Turning to the bacteriology of cheese, Miss M. E. Sharpe and Miss J. Naylor (Shinfield) commented on the desirability of adding bacteria to maintain particular flavours, and emphasized the importance of the starter in this respect. They examined the survival of lactic bacteria in Cheddar cheeses over periods up to six months and found that the streptococcal types declined in number but the lactobacilli grew slightly. Of the three media used for isolating the various types, acetate agar was best for the lactobacilli. In a similar vein, and on the assumption that farm-house cheeses have a better flavour than factory-made cheeses because they are made under less rigorously controlled conditions and with less pure cultures, Miss N. J. Hall (Reading) examined the associated growths of *Streptococcus lactis*, an organism found normally in cheese, and *Escherichia coli*, a potential common contaminant. Mixed cultures added to the cheese vats undoubtedly affected the flavours according to the amounts of the cultures used, and fortunately the *E. coli* always died out. In mixed cultures maintained in continuous daily subculture at 30° and 37°, *E. coli* disappeared in a few days, and it was not detected in cheese a few weeks after manufacture. The influence of rennet on bacteriophage multiplication in milk prior to making cheese was discussed by L. J. Meanwell and Miss N. Thompson (London). They found that rennet added to milk within 30 min. of inoculating with a starter culture protects the culture against phage attack by stimulating cell production and suppressing phage multiplication. This prolongs the time before phage numbers equal cell numbers and so allows acid production to continue for some hours.

H. B. Hawley (Yeovil) gave two papers, one of which was in collaboration with G. Bourne (London), on the bacteriological deterioration of processed cheese, and its micro-structure and fat distribution. The papers were well illustrated by slides which clearly demonstrated the effects of different contaminating bacteria on the appearance of the cheese, such as 'eyes' in Cheddar cheese due to propionic acid bacteria and deformation in packet cheeses due to bacterial spores. Histologically, the micro-structure has many resemblances to pathological specimens, and bacteria can be seen associated with the fat globules.

Having disposed of the papers on milk and cheese, the conference heard M. Lev and C. A. E. Briggs (Shinfield) describe their investigations into the establishment of the gut flora in the newly hatched chick. Somewhat surprisingly, they found a balanced flora to be present after two days, and even after 24 hr. the broad groupings are established. Highest counts are found in the cæcum, and the next highest in the crop.

The effect of various detergents on the activities of a number of quaternary ammonium compounds at different temperatures and in waters of different hardness was the subject of a paper by Miss C. M. Cousins and L. F. L. Clegg (Shinfield). In general, lower temperatures meant lower activities, although the temperature coefficients varied with the compounds. Water hardness was very significant, to the extent that a mixture active at 50 p.p.m. in distilled water may not be completely effective in a hard water at 200 p.p.m. The activity of the quaternaries themselves bore little relation to their activities in detergent mixtures.

Another topic discussed was the preservation of organisms of the *Pseudomonas* type under mineral oil. Miss M. E. Rhodes (Reading) emphasized the need for cultures to be totally sealed with the oil to effect preservation and described it as an improved method because only slight changes occurred in the saccharolytic and proteolytic properties of the cultures so treated. She preferred it to freeze-drying. Of 170 organisms examined, only 6 per cent changed their reactions to sucrose and 2 per cent to galactose, whereas those maintained in continuous culture underwent significant changes. W. B. Hugo (Nottingham) described a new, or rediscovered, *Pseudomonas* species which is very similar to, or identical with, *Ps. lemonnieri*. It occurred as a contaminant and was singled out for investigation because it produces a characteristic blue pigment which is different from pyocyanin as shown by ultra-violet absorption spectra. The pigment is protein in nature, insoluble in water, and is only produced aerobically in the presence of carbohydrates.

The last two papers dealt, in effect, with the systems of classification of organisms. S. T. Cowan (Colindale) discussed the biochemical and other characteristics of various members of the coli-aerogenes group of bacteria, showing how irregular are some of the divisions of the different genera. This was illustrated by examples such as *Klebsiella pneumoniae*, *Kl. aerogenes*, *Cloaca* and *Citrobacter* spp. He pointed out that any system of nomenclature depends on the system of classification used, and added that utility is another factor to be considered. In a similar way, Joan Taylor (Colindale) discussed a subject on which opinions have varied from time to time, namely, the pathogenicity of *E. coli*. This organism as an infective agent is essentially confined to babies three to six months old. It is infectious in close communities; but the same serotypes are found universally. These serotypes may differ slightly in their biochemical characteristics; but fundamentally they are all typical *E. coli*. At the same time, they may have serological identities with certain of the *Salmonella* group. So what of their classification ?

These papers will be published in full at a later date in the *Journal of Applied Bacteriology.*

INTERNATIONAL LIGHT METALS CONGRESS AT LEOBEN

THE international Light Metals Congress, held in Leoben, Austria, during June 7–9, was the third such meeting there, the previous ones being in 1934 and 1948, and as on the former occasions, the purpose of the Congress was to give a comprehensive picture of the present state of the light metals industry and to permit informal discussion and exchange of views among the delegates. Organized by the Montanistische Hochschule with the assistance of the Austrian light metals industry, the Congress was attended by more than three hundred and fifty representatives from nineteen countries. The programme included an exhibition of the applications of aluminium, various visits and social functions, and six technical sessions at which more than thirty papers were read. In addition to the usual facilities for lantern slides and films, arrangements were made for the whole proceedings to be televised to a second audience in the overflow meetings.

The opening session was devoted to reviewing the part played by light metals in the economy of the major countries represented, which included Austria, France, Great Britain and the British Commonwealth, Italy, the German Federal Republic, Switzerland and the United States. The papers were contributed by W. C. Binz, R. Carmina, Th. Dirksen, A. Dumas, F. C. Frary, B. K. Klein, G. V. Schulthess and W. J. Thomas, respectively. All told much the same story of rapid post-war growth of the industry, encouraged by the continuing strong demand for light metal products. An interesting fact brought out by these papers is that the present and estimated future demand for aluminium exceeds existing supplies of electrical energy and bauxite—the chief raw materials of the industry—so that attention is being turned to additional sources, notably those in undeveloped areas of western Canada and Africa.

In the session dealing with advances in metallurgy, M. O. Sem (Oslo) described the importance of the Söderberg electrode in modern large electrolytic cells, and P. Gross (Stoke Poges) examined the conditions to be fulfilled in the sub-halide distillation of aluminium. A. Brenner (Lend) gave an account of the production, properties and uses of super-purity aluminium—a material which is of growing industrial importance. The single paper devoted to magnesium was presented by C. J. P. Ball (London); this was a comparative survey of the methods currently used for the extraction of magnesium.

Interest in titanium, the latest member of the light metals family to be used industrially, was evidenced by the five papers dealing with this metal. Two of these described extraction processes: R. Kieffer (Reutte) summarized the present methods of production, with figures illustrating the astonishing growth in output during the past few years, and E. Fitzer, H. Hofbauer and H. Hohn gave an account of a process in which an alkali amalgam is used to reduce titanium tetrachloride to titanium amalgam, the mercury being afterwards removed by distillation. M. Hansen (Frankfurt) dealt with the physical metallurgy of titanium and its alloys.

An encouraging sign of improved international relations was the participation of scientists from the U.S.S.R., who contributed two papers on the metallurgy of titanium alloys, including one by Dr. M. A. Pavlov, of the Moscow Academy of Sciences.

Papers dealing with the technology of light metals included one on foundry practice by Prof. A. von Zeerleder, a pioneer of the light metals industry, who discussed the advances in foundry technique from the historical point of view, with emphasis on recent improvements in gating systems. K. Schneider (Nuremberg) described the methods used in the recovery and treatment of secondary metals, and M. Lamourdedieu (Paris) dealt with current practice in the rolling of light metals. Much interest was aroused by R. D. Hamer's paper on experience with the continuous casting and rolling of aluminium strip, which was supported by a short film depicting the operation of installations at Rorschach and Banbury. During recent years a demand has arisen from the aircraft industry for large structural forgings to replace members which otherwise would be built up from extrusions and sheet, and G. W. Richards and C. Wilson (Birmingham) discussed some of the metallurgical problems which arise in the production of these forgings, particularly the control of internal stresses. An account of recent advances in welding practice, including inert gas welding, cold welding and the high-frequency welding of tubes, was given by E. Zurbrügg (Neuhausen), and G. Luft and F. Sacchi (Novara) read a paper on surface treatment with reference to Italian experience.

Six papers were devoted to topics in physical metallurgy and metallography. R. Mitsche (Leoben) described the effect of superheating on the structure of as-cast metals, while E. M. Onitsch-Modl (Winterthur) surveyed the powder metallurgy of aluminium, magnesium and titanium. P. Brenner (Lend) discussed an urgent engineering problem, that of the fatigue strength of aluminium alloys and its relation to other properties of the material. The connexion between processing conditions and the properties of extrusions was considered by E. Nachtigall (Ranshofen), and G. Siebel (Singen) discussed a perennial production problem—the earing of certain aluminium alloys during deep drawing and the influence of processing variables on this behaviour. E. Schmid (Vienna) contributed a necessarily brief account of the part played by lithium, beryllium, magnesium, aluminium, silicon and titanium in certain applications to physics, with particular reference to nuclear energy.

The final session was devoted to applications of the light metals. The way in which new applications are evolved, developed and finally established was discussed by de Ridder, and M. Langegger (Ranshofen) described the various applications of semi-finished products in Austria. L. Kirste (Vienna) examined the essential requirements to be met for successful light-weight construction, and C. Panseri (Novara) mentioned some of the problems which arise when aluminium is used in architecture; he also described a new magnesium-silicide alloy which has been developed in Italy for spandrel sections. A comprehensive paper on the use of aluminium for transport by land, sea and air was contributed by J. J. Baron (Paris), in which details were given of the various applications. A. Taranger (Oslo) discussed another field of use, that of rigid wall cans for processed foods; he concluded that the technical obstacles to the use of aluminium in canning have been largely overcome, and therefore wider employment is a matter of economics. J. C. Bailey (London) dealt with electrical engineering, a field in which aluminium has made, and is still making, great strides and in which it occupies a favourable economic position.

In addition to the foregoing, the following papers were submitted in summary form: improvements in the quality of aluminium–silicon alloys (W. Thury); reactivity and specific consumption of anode carbon in the industrial electrolytic production of aluminium (A. Vajna de Pava); and chemical background to the wet alkaline process of Bayer for extracting aluminium oxide hydrate from bauxites (F. Heyd).

The full text of all the papers will be published, in German, in the journals *Aluminium* (Aluminium-Verlag GmbH., Düsseldorf) and *Berg- und Hüttenmännischen Monatsheften* (Springer-Verlag, Vienna) this autumn.

THE MEDICAL RESEARCH COUNCIL

REPORT FOR 1954–55

THE report of the Medical Research Council for the year 1954–55* follows the plan used in recent years of giving summaries only of the work of the Council's many research establishments, the main part of the report being devoted to a discussion of selected aspects of the general trend of medical research. As the report emphasizes, every conspicuous advance in medical research depends on a mass of unspectacular work and on team work, to which every individual taking part, whatever his status, contributes essential skill or knowledge.

Among the subjects selected for discussion this year the control of poliomyelitis is of popular interest, and an account is given of the vaccines now in use as prophylactics against this disease. The results of the American trial of the Salk vaccine, so admirably conducted, showed that this vaccine reduced paralytic poliomyelitis among children aged 6–9 years by 28 per cent, the protection increasing with age. After revision of the safety tests, many millions of children in the United States and Canada have been vaccinated. The report describes the work being done in Britain on the manufacture of a somewhat different vaccine and on tests of its safety and on trials of it. It then goes on to discuss the epidemiology of poliomyelitis and the increased risk of development of the disease in children who have recently been inoculated with a combined prophylactic against diphtheria and whooping-cough or who have recently had their tonsils removed.

Other subjects discussed in this part of the report are recent research on influenza, vaccination against tuberculosis, antibody immunity, the mechanism of allergic reactions, the causes and control of œdema due to diseases of the kidneys, human genetics, developments in biophysics and the fallacies of the design of industrial work.

The rest of the report, after outlining the administration of the Council's work, epitomizes its research programme and gives the names of its personnel, summaries of the programmes of the many research units and a list of the many publications reporting the work of the Council's staff and the work of the staffs of the Institute of Cancer Research and the Public Health Laboratory Service. The report is, in fact, a complete guide to the Council's many-sided activities. It would be hard to find anywhere a finer record of the devoted efforts of many people of different skills to better the health of man to-day and to make the world a better place for generations to come.

CRYSTALLINE CYTOCHROME C

Preparation of Crystalline Cytochrome c from Yeast

THE first crystallization of cytochrome *c* was reported from muscle of the king penguin by G. Bodo[1]. Cytochrome *c* has been crystallized by us from more convenient sources, such as baker's yeast, beef heart[2] or pig heart[2]. In this communication is reported the isolation from yeast of crystalline cytochrome *c*, which was shown to be a homogeneous protein by electrophoretic, ultracentrifugal and chromatographic criteria[2].

Baker's yeast, treated with ethylacetate (1/7 vol.) for one hour, was twice washed by suspending in tap water (5 vol.) for one hour while keeping the suspension at *p*H 7–8 with ammonia. The washed yeast was twice extracted with 10 per cent ammonium sulphate solution (the same volume as the yeast cake) for fifteen hours. The ratio of extinction at 550 mμ of the reduced pigment to the extinction of 280 mμ of oxidized pigment which is abbreviated to R^{550}_{280} was 0·01. The extract, after being dialysed against tap water for two days, was passed through a column of cation exchange resin, 'Duolite *CS*-101' (buffered at *p*H 7·0), which has a greater capacity for adsorption of cytochrome *c* than the 'Amberlite' *IRC*-50 (*XE*-64) ordinarily used[3-5]. After washing the column with dilute ammonium sulphate solution (0·05 *M*), the cytochrome *c* was eluted with 0·2 saturated ammonium sulphate solution (eluate: $R^{550}_{280} = 0·2–0·3$). The solution containing about 0·05 per cent oxidized cytochrome *c* was saturated with ammonium sulphate at *p*H 5·0 and the resulting precipitate was removed (filtrate: $R^{550}_{280} = 0·4–0·7$). The filtrate was dialysed and cytochrome *c* further concentrated using *CS*-101 as before except that ammonium phosphate buffer solution (1·0 *M*, *p*H 7·0) was used for the elution.

The cytochrome *c* was purified by the method of Margoliash[4] with some modifications in which the resin, *XE*-64, treated with sodium hypochlorite and ammonium phosphate buffer solution (0·4 *M*, *p*H 7·0) was used. The cytochrome *c* eluted in the oxidized form at about four hold up volumes was collected and highly concentrated using a small column of *CS*-101 (eluate: $R^{550}_{280} \doteqdot 1·15$). The solution, containing more than 10 per cent oxidized cytochrome *c*, was nearly saturated (about 0·85 saturation) with ammonium sulphate at *p*H 5·0 and the slight amount of resulting precipitate was removed (supernatant: $R^{550}_{280} \doteqdot 1·2$).

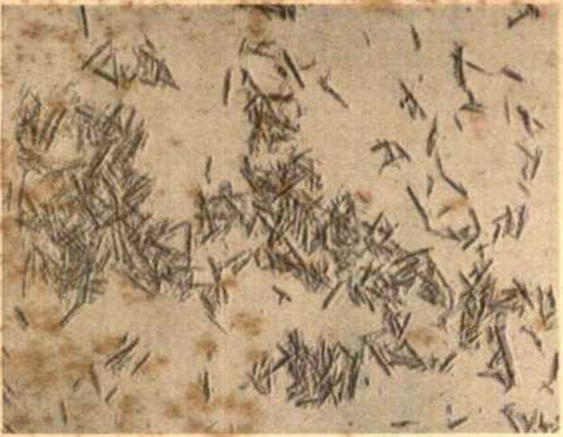

Fig. 1. Crystalline yeast cytochrome *c* (rod form, × 1,500)

The cytochrome *c* contained in the supernatant was reduced with the minimum amount of ascorbic acid, adjusted to about *p*H 9·0 with 30 per cent ammonia (about 1/30 vol.), and then saturated by the addition of finely powdered ammonium sulphate in order to precipitate cytochrome *c*. When the resulting suspension was allowed to stand for 3–5 days, the precipitated cytochrome *c* changed into very small crystals. After centrifugation, the crude crystals were dissolved in the minimum amount of water (about 1/3 vol. of the crystals) (crude crystals: $R^{550}_{280} = 1{\cdot}25$). When finely powdered ammonium sulphate was added to the above solution until it became slightly turbid (about 0·8 saturation), small needle-like crystals appeared after one or two hours and then gradually changed into fairly large needles or rods as shown in Fig. 1 (first crystals: $R^{550}_{280} = 1{\cdot}28$). All the work was carried out at room temperature (10–15° C.). Recrystallization was carried out in the same way; but the purity was not increased.

The crystallization of oxidized cytochrome *c* was performed in almost the same way, and the crystals with the same shape and purity as in the case of reduced cytochrome *c* were obtained. Crystallization was also carried out from a mixture of oxidized and reduced cytochrome *c*. However, it seems to be most convenient to crystallize the protein in its reduced form, since the solubility of the reduced protein in ammonium sulphate solution appears to be somewhat smaller than that of the oxidized form.

This method was quite reproducible and also applicable to the crystallization of the hæmoprotein from dry yeast with a few modifications. The yield of the crystals was about 50 mgm. from 1 kgm. of compressed yeast or 0·3 kgm. of dry yeast.

We wish to express our thanks to the Oriental Yeast Co., Ltd., for the supply of the source material, to the Japan Organo Co., Ltd., for the resin *XE*-64, and to the Nippon Kiko Co., Ltd., for *CS*-101.

Preparation of Crystalline Cytochrome c from Beef and Pig Heart

CRYSTALLINE cytochrome *c* was prepared from beef and pig heart by a method similar to that used for yeast[1] with a few modifications. Each of these two crystalline preparations was shown to be a homogeneous protein by electrophoretic, ultracentrifugal and chromatographic criteria[2] and to give the highest ratio of the extinction coefficient of the reduced form at 550 mμ to that of the oxidized form at 280 mμ ($R^{550}_{280} = 1{\cdot}29$ in beef, $R^{550}_{280} = 1{\cdot}28$ in pig).

Heart muscle, freed of fat and ligaments and washed with tap water, was minced and then extracted twice with 0·1 saturated ammonium sulphate solution. The residue was removed by filtration through a cloth using a press. In the case of beef heart, the residue was stored as a source of cytochromes *a* and *b*. In the case of pig heart, crystalline fumarase and lactic dehydrogenase were obtainable together with cytochrome *c* from the extract by separating the former two enzymes by a fractionation with ammonium sulphate at 0·8 saturation. In the case of both beef and pig, cytochrome *c* was concentrated by the slightly modified methods of Keilin and Hartree[3,4] from the filtrate from 0·8 saturated ammonium sulphate.

The concentrated cytochrome *c* was dissolved, dialysed against ammonium phosphate buffer solution (0·05 *M*, *p*H 7·0), and then further concentrated using 'Duolite' *CS*-101 as in the case of yeast[1] (concentrate: $R^{550}_{280} = 1{\cdot}1$–$1{\cdot}15$). The procedure followed exactly that used in the preparation of cytochrome *c* from yeast except that when the concentrated cytochrome *c* was chromatographed on *XE*-64 the buffer solution contained 0·25 *M* ammonium instead of 0·4 *M* (main peak: $R^{550}_{280} = 1{\cdot}2$). The cytochrome *c* thus obtained was more soluble in concentrated ammonium sulphate solution than that obtained from yeast, but the shapes of the crystals in various stages of the crystallization were almost identical.

This method was quite reproducible and the yields of the crystals from 1 kgm. of beef and pig heart were about 30 mgm. and 20 mgm., respectively.

The shapes of the cytochrome *c* crystals may be divided into four types: needle, rosette (Fig. 2), leaflet (Fig. 3) and slender rod-like forms. All these types have also been observed in crystals obtained from yeast, though the shape of the second type,

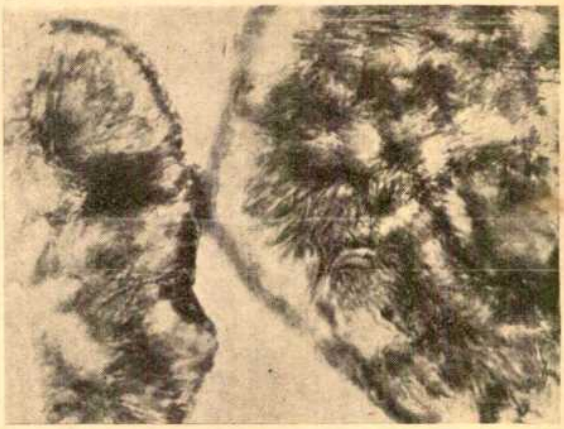

Fig. 2. Crystalline pig heart cytochrome *c* (rosette form, × 1,500)

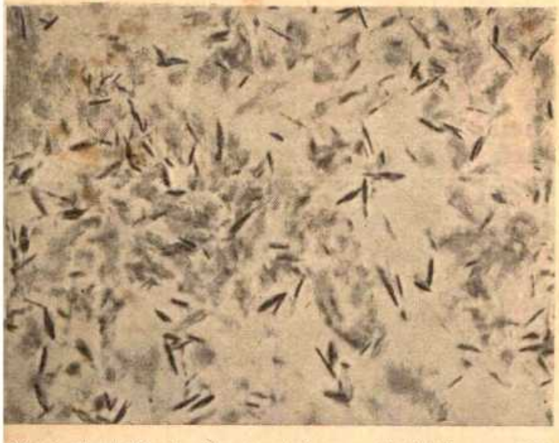

Fig. 3. Crystalline beef heart cytochrome *c* (leaflet form, × 900)

osette, of yeast was somewhat different from the ther. Needle and rosette crystals have usually ppeared in the earlier period in the first crystallizaion and then changed into the leaf-like type which ppeared also in the earlier period of the recrystalzations. These three types have often been changed nto the slender rod-like form by careful recrystalzations and by allowing the suspension of crystals o stand for a very long time. It was supposed from hese observations that the needle type might be a ery small form of the rod type, while the rosette nd leaflet types might comprise grouped forms of he needle. No other shapes of true crystalline cytohrome *c* have yet been obtained from the above hree different sources. These cytochromes *c* have ever been crystallized from a dilute solution, as in he method of Bodo[5] using king penguin muscle, lthough crystals of some other substance with clear dges slightly coloured (presumably by the adsorpion of cytochrome *c*) have sometimes appeared, ogether with an amorphous precipitate of cytohrome *c*, under the conditions used by him.

Comparison of Properties of Crystalline Cytochrome c from Yeast, Beef Heart and Pig Heart

A few physical and biological properties of the rystalline cytochrome *c* obtained from baker's yeast, eef heart and pig heart by the methods previously escribed[1] are here recorded.

Absorption spectra of the three crystalline cytohrome *c*'s were found in the ultra-violet and visible egions to be practically identical with one another, nd also with non-crystalline samples prepared from orse heart by the method of Keilin and Hartree[2] hrough the visible range. However, in the ultraiolet region at about 280 mμ, a difference was bserved between the crystalline preparations and the non-crystalline preparations (Fig. 4). This suggests the impurity of the latter.

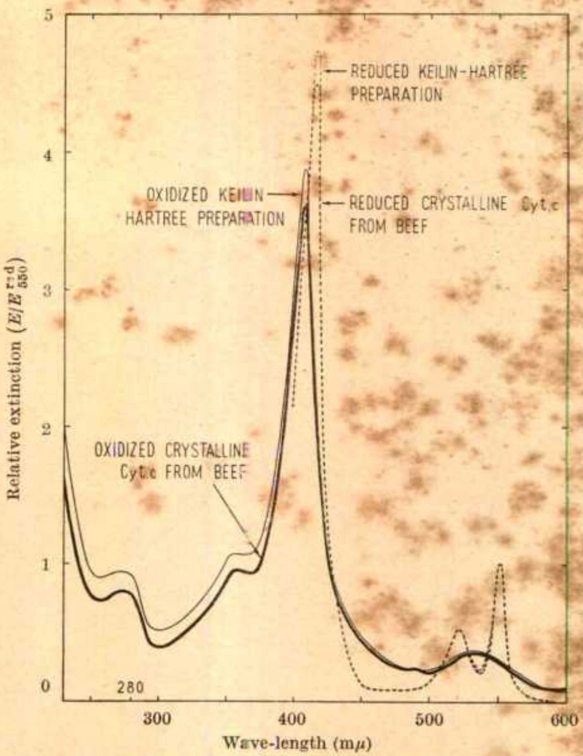

Fig. 4. Absorption spectra of crystalline cytochrome *c* from beef and Keilin–Hartree preparation from horse heart

Electrophoreses were performed at *p*H 9·0 using a sodium glycine–sodium chloride–hydrochloric acid buffer system of ionic strength 0·1. Each of the crystalline preparations in the oxidized form migrated in the electrical field as a homogeneous substance. Further analyses are now in progress under other conditions in order to confirm the homogeneity of these preparations and also to determine their isoelectric points.

Ultracentrifugal experiments were performed by Dr. K. Fukai, of the Institute for Microbial Diseases, University of Osaka, using a 'Spinco' Model-*E*; the runs were carried out in sodium chloride solution of *p*H 6·0 and ionic strength of 0·2 at a protein concentration of 0·5–0·2 per cent. All the above three crystalline preparations showed only one peak in the centrifugal field at 59,780 r.p.m. (Fig. 5).

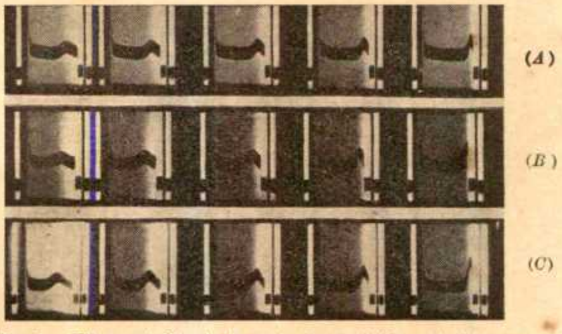

Fig. 5. Ultra-centrifugal diagram of crystalline cytochrome *c* from (*A*) yeast, (*B*) beef heart, and (*C*) pig heart. Solvent, 0·2 *M* sodium chloride; protein concentrations, (*A*) and (*B*) 0·2 per cent, (*C*) 0·45 per cent; 59,780 r.p.m. in a 'Spinco' Analytical *A* rotor with 12-cm. cell; interval, (*A*) 16 min., (*B*) and (*C*) 34 min.

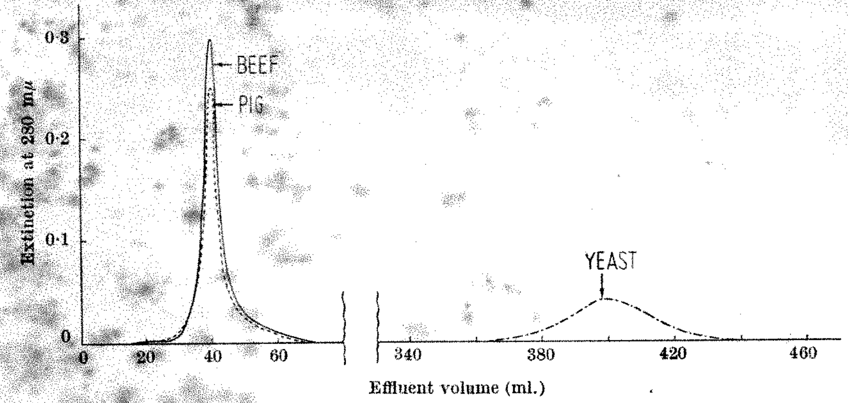

Fig. 6. Chromatograms of crystalline cytochrome *c* from yeast, beef heart and pig heart. Column, 'Amberlite' *XE*-64, 150–300 mesh, 1 cm. × 26 cm.; buffer, ammonium phosphate pH 7·0, 0·3 M ammonium; rate of flow, 10 ml./hr.

Analytical chromatography of the oxidized forms was carried out on a column of ion exchange resin, 'Amberlite' *XE*-64, according to the method of Hirs, Moore and Stein[3], except that resin treated with sodium hypochlorite, and ammonium phosphate buffer solution of pH 7·0 containing 0·3 M ammonium were used. In each case only one clear peak was obtained, though the elution volumes for the yeast preparation were very different from the other two (Fig. 6).

Biological activities of the three cytochromes *c* were tested in the succinic oxidase system and the cytochrome oxidase system prepared from beef heart muscle by the method of Keilin and Hartree[4]. The efficiencies of the three preparations in these systems were almost the same based on the extinction a 550 mμ in the reduced form.

DETERMINATION OF INTERMEDIARY METABOLITES BY ENZYMIC FLUORIMETRY

By Dr. P. GREENGARD
National Institute for Medical Research, Mill Hill, London, N.W.7

WORK now in progress on the metabolism of the peripheral nervous system requires more sensitive methods than are generally available for the assay of various intermediary metabolites. In recent years increasingly widespread use has been made of the difference of ultra-violet absorption properties of oxidized and reduced pyridine nucleotides for the determination of intermediary metabolites. These compounds also differ in their fluorescence properties. Reduced diphosphopyridine nucleotide and reduced triphosphopyridine nucleotide are fluorescent, whereas the corresponding oxidized forms are not. This difference in the fluorescence properties of the reduced and oxidized forms has been used in the determinations to be described as the basis of a direct method for the estimation of intermediary metabolites at levels as low as 2×10^{-10} mole. This is about 100 times the sensitivity of the ultra-violet absorptiometric methods hitherto used for such determinations.

Any of the large number of compounds capable of being enzymatically coupled, by one or more enzymes, either to the oxidation or to the reduction of either of the two nucleotides should be amenable to assay by this method. So far, this fluorimetric method has been found suitable for the determination of a number of compounds, including pyruvic acid, phosphoenolpyruvic acid, adenosine diphosphate, adenosine triphosphate and glucose-6-phosphate. The problem of non-absolute enzyme specificity, such as keto-acids other than pyruvate reacting with lactic dehydrogenase[1] and nucleotides other than adenine nucleotides reacting with 'adenine nucleotide enzymes', are of course, similar to those encountered in the spectrophotometric assay methods.

The measurements reported here were made with a Hilger 'Spekker' absorptiometer modified in this laboratory to serve as a fluorimeter using an *E.M.I* 6097*B* photomultiplier as the light detector.

Pyruvic acid. This compound was estimated, as in the spectrophotometric method of Ochoa *et al.*[2], in the presence of lactic dehydrogenase and excess reduced diphosphopyridine nucleotide. One molecule of the latter is oxidized for each molecule of pyruvate present, according to the following reaction:

$$\text{pyruvate} + \text{reduced diphosphopyridine nucleotide} \rightarrow \text{lactate} + \text{diphosphopyridine nucleotide} \quad (1$$

The disappearance of reduced diphosphopyridine nucleotide, determined by decrease in fluorescence is proportional to the pyruvate present. It can be seen from Fig. 1 that pyruvate can be estimated in amounts of $2{\cdot}5 \times 10^{-10}$ mole in a volume of 1 ml

Although diphosphopyridine nucleotide and triphosphopyridine nucleotide do not ordinarily fluoresce, they can be made to do so by condensation with ketones in an alkaline medium[3]. These condensation products are many times more fluorescent than the reduced pyridine nucleotides, the fluorescence of which is not increased by this treatment. The

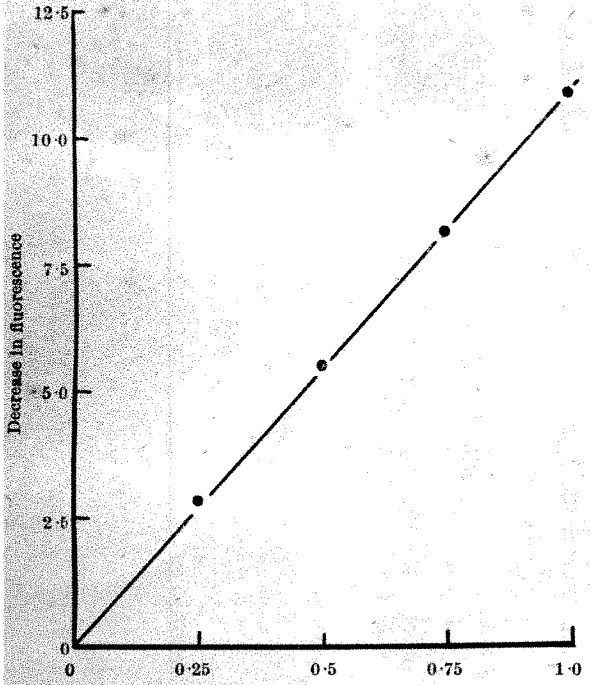

Fig. 1. Assay of pyruvate: Reaction mixture (1 ml.) contained 10 μmol. triethanolamine, *p*H 7·7, 0·5 μmol. ethylenediaminetetra-acetate, *p*H 7·4, 1·6 mμmol. reduced diphosphopyridine nucleotide and indicated amounts of pyruvate. Reaction started by addition of 0·01 ml. (40 Bücher units) of lactic dehydrogenase. Readings taken every minute at room temperature until stable value is obtained. Blank corrections (no added pyruvate) have been applied

combined use of lactic dehydrogenase, excess pyruvate and this ketone procedure was previously employed for the estimation of reduced diphosphopyridine mucleotide[4]. The procedure has now been used for estimating pyruvate by using an excess of reduced diphosphopyridine nucleotide. Following the completion of reaction (1) the diphosphopyridine nucleotide formed is measured by the fluorescence of its ketone condensation product. With this procedure, pyruvic acid was estimated in amounts as small as $2 \cdot 5 \times 10^{-11}$ mole (Fig. 2).

The ten-fold greater sensitivity of the ketone procedure suggests it as the method of choice for the estimation of pyruvate and other compounds when such extra sensitivity is desired. On the other hand, the direct use of reduced diphosphopyridine nucleotide fluorescence for these estimations has certain advantages. One is the greater simplicity of the procedure. Another is that the progress of the reaction can be followed continuously, with the result that the termination of the reaction can be ascertained with greater ease and accuracy. Finally, a second compound can be estimated on a given aliquot (see estimation of adenosine diphosphate and phosphoenolpyruvate).

Adenosine diphosphate and phosphoenolpyruvate. By a simple extension of the fluorimetric method for the assay of pyruvate, either adenosine diphosphate or phosphoenolpyruvate may be estimated at similar low levels. As in the spectrophotometric procedure of Kornberg and Pricer[5], the addition of Mg^{++}, K^{+} and pyruvic phosphokinase to the reaction mixture used for the determination of pyruvate permits the estimation of either of these compounds according to the reaction:

adenosine diphosphate + phosphoenolpyruvate →
adenosine triphosphate + pyruvate (2)

the pyruvic acid formed reacting according to equation (1). In the presence of excess phosphoenolpyruvate, the decrease in fluorescence gives a measure of the adenosine diphosphate present. As shown in Fig. 3, the sensitivity of the method is such as to allow for the estimation of less than 2×10^{-10} mole of adenosine diphosphate in a 1·0 ml. volume. If pyruvate is present, it can be estimated separately as above and the adenosine diphosphate content obtained by difference. Alternatively, pyruvate and adenosine diphosphate can be determined on a single aliquot by first estimating the pyruvate in the presence of lactic dehydrogenase and then adding pyruvic phosphokinase, Mg^{++} and K^{+} for the estimation of adenosine diphosphate. It was found necessary to withhold the addition of Mg^{++} until the pyruvate estimation was completed, since even highly purified samples of lactic dehydrogenase contain small traces of pyruvic phosphokinase and therefore some adenosine diphosphate might be estimated along with the pyruvate.

The same principle when applied to the determination of phosphoenolpyruvate by adding adenosine diphosphate in excess gave a similar sensitivity.

Glucose-6-phosphate and adenosine triphosphate. Glucose-6-phosphate is estimated, as in the spectrophotometric method of Ochoa *et al.*[6], in the presence of glucose-6-phosphate dehydrogenase (*Zwischenferment*) and excess triphosphopyridine nucleotide. One molecule of triphosphopyridine nucleotide is reduced for each molecule of glucose-6-phosphate present according to the reaction:

glucose-6-phosphate + triphosphopyridine nucleotide
→ 6-phosphogluconic acid + reduced triphosphopyridine nucleotide (3)

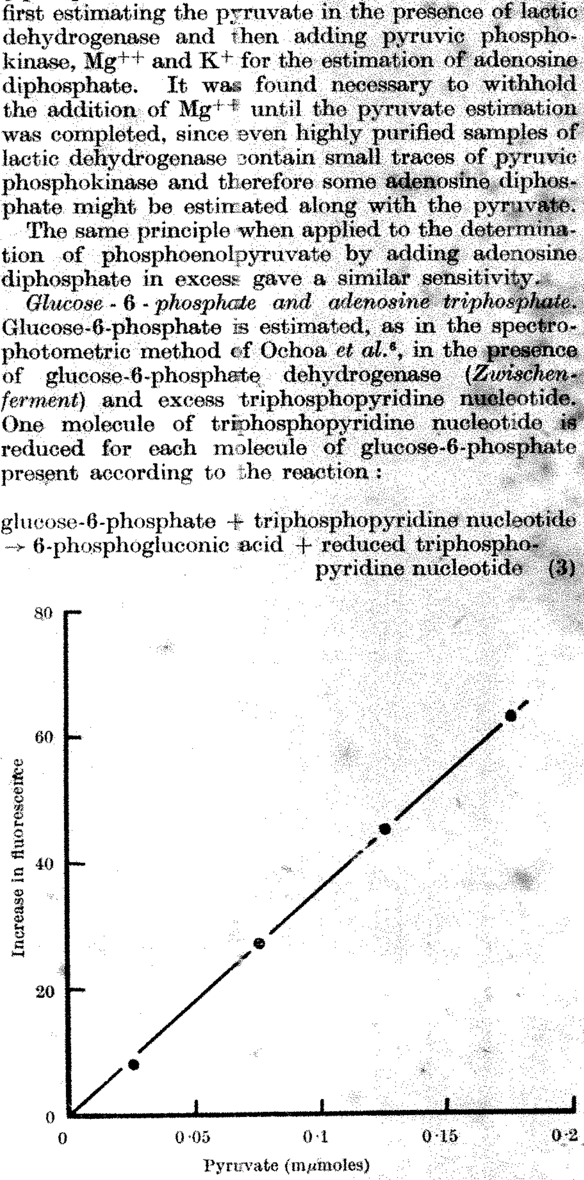

Fig. 2. Assay of pyruvate, ketone method. Reaction mixture (0·5 ml.), containing 5 μmol. triethonalamine, *p*H 7·4, 0·2 μmol. ethylenediaminetetra-acetate, *p*H 7·4, 0·25 mμmol. reduced diphosphopyridine nucleotide, indicated amounts of pyruvate and 40 Bücher units of lactic dehydrogenase, was incubated at 39° for 15 min., followed by addition, with mixing, of 0·2 ml. of 0·0002 *M* manganous chloride in methyl ethyl ketone, 0·2 ml. of 4·2 *N* sodium hydroxide, and, after waiting 5 min., 0·95 ml. of 1·0 *N* hydrochloric acid. Solution boiled 5 min., cooled and readings taken. Blank corrections (no added pyruvate) have been applied

The formation of reduced triphosphopyridine nucleotide, determined by increase in fluorescence, is proportional to the glucose-6-phosphate present.

As in the spectrophotometric procedure of Kornberg[7], the addition of hexokinase and glucose to the reaction mixture used for the estimation of glucose-6-phosphate permits the estimation of adenosine triphosphate according to the reaction:

adenosine triphosphate + glucose → adenosine diphosphate + glucose-6-phosphate (4)

the glucose-6-phosphate formed reacting according to equation (3). This is illustrated in Fig. 4; less than 2×10^{-10} mole of adenosine triphosphate was estimated in a 1·0 ml. volume. If glucose-6-phosphate is present, it can be estimated separately as above in the absence of reaction (4) and the adenosine triphosphate content obtained by difference.

Alternatively, glucose-6-phosphate can be estimated, according to the procedure of Slater[8], in the presence of excess reduced diphosphopyridine nucleotide and adenosine triphosphate using an enzyme system from rabbit muscle. In this procedure, glucose-6-phosphate is measured by the oxidation of reduced diphosphopyridine nucleotide. By measuring the decrease in fluorescence as the reduced diphosphopyridine nucleotide was oxidized, 4×10^{-10} mole of glucose-6-phosphate was readily estimated in a volume of 7·3 ml.

A limitation in the estimation of metabolites at the level of sensitivity potentially available by fluorimetry is the purity of the enzymes used. Among the many substances which should be readily estimated by this fluorescence method are isocitrate, α-ketoglutarate and the triose phosphates, since the respective enzymes catalysing reactions between these intermediates and the pyridine nucleotides have been crystallized.

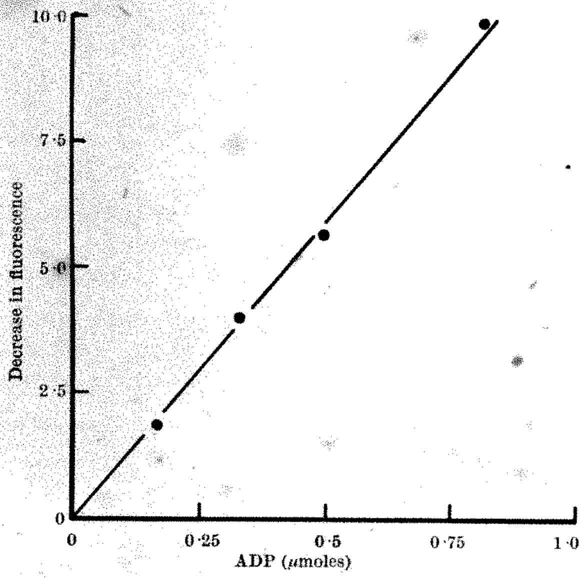

Fig. 3. Assay of adenosine diphosphate. Reaction mixture (1·0 ml.) contained 10 µmol. triethanolamine, pH 7·7, 0·5 µmol. ethylenediaminetetra-acetate, pH 7·4, 1·6 mµmol. reduced diphosphopyridine nucleotide, 20 µmol. magnesium sulphate, 80 µmol. potassium chloride, 1·6 mµmol. phosphoenolpyruvate and indicated amounts of adenosine diphosphate. Reaction started by addition of 0·01 ml. (40 Bücher units) of lactic dehydrogenase and 0·03 ml. (40 Bücher units) of pyruvic phosphokinase. Readings taken every minute at room temperature until stable value was obtained. Blank corrections (no added adenosine diphosphate) have been applied

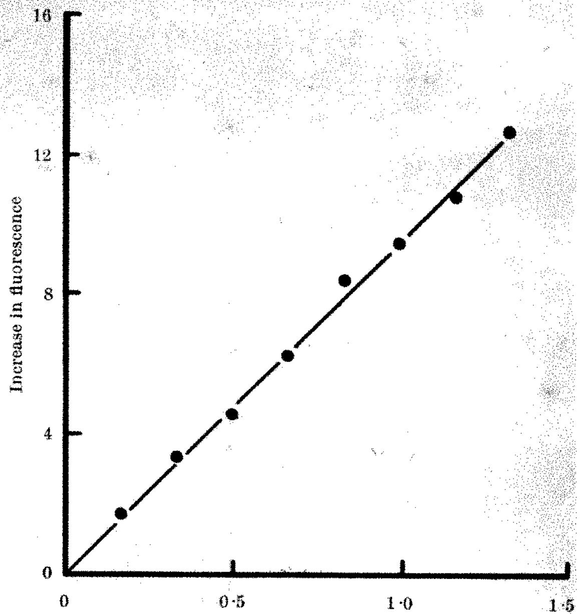

Fig. 4. Assay of adenosine triphosphate. Reaction mixture (1·0 ml.) contained 35 µmol. triethanolamine, pH 8·2, 0·2 µmol. ethylenediaminetetra-acetate, pH 7·4, 2·2 mµmol. triphosphopyridine nucleotide, 5·0 µmol. magnesium chloride, 100 µmol. glucose and indicated amounts of adenosine triphosphate. Reaction started by addition of 0·1 ml. (0·075 Kornberg units) of glucose-6-phosphate dehydrogenase containing hexokinase. Blank corrections (no added adenosine triphosphate) have been applied

Just as the spectrophotometric assay methods have been suitable for the estimations both of intermediary metabolites and of the activities of the related enzymes catalysing the reactions between these metabolites, so the fluorimetric methods described here for the estimation of intermediary metabolites can be used, with slight alterations, for the very sensitive estimation of enzyme activities. In fact, the activities of the enzymes used in this work were usually tested fluorimetrically. Theorell *et al.*[9] have found the sensitivity of fluorescence measurements to be very useful in their study of the reaction mechanisms of pyridine nucleotide enzyme systems.

Note added in proof: Lowry *et al.*[10] have used a similar procedure for the estimation of tissue-levels of glutamic dehydrogenase.

I am grateful to Prof. Th. Bücher for a gift of crystalline lactic dehydrogenase and pyruvic phosphokinase. It is a pleasure to thank Prof. Th. Bücher, Dr. W. Feldberg, Prof. E. C. Slater and Dr. T. S. Work for stimulating discussions. This work was carried out during the tenure of the Doris Duke Foundation Fellowship of the National Paraplegia Foundation, U.S.A.

Electron Microscope Observations of Periodicities in the Surface Structure of Tobacco Mosaic Virus

X-RAY diffraction data and chemical evidence suggest that the protein content of tobacco mosaic virus rods is built up of small sub-units[1]. A model has been proposed[2] in the form of a helix of pitch of 23 A. and repeat distance of 69 A.

By electron microscopy using the carbon replica technique[3] we have obtained direct evidence for a structure repeating at 46 A. along the axis of the virus. A longitudinal structure of ridges and furrows has also been resolved which may indicate a polygonal cross-section for the virus rod. This is difficult to reconcile with recent deductions[4] from X-ray diffraction experiments that the virus rod has a hollow centre of radius 20 A. and a concentration of nucleic acid at a radius of 40 A.

A 'type' strain of tobacco mosaic virus was grown in tobacco plants and the virus isolated by the usual ammonium sulphate precipitation procedures. The suspension was dried on carefully cleaned glass surfaces and carbon was evaporated directly on to the preparation at an angle of about 30° from the horizontal. After stripping the carbon from the slide, the replica was placed in $2N$ potassium hydroxide at 60° C. to remove any virus rods remaining attached to the carbon. Finally, the replica was washed using the methods described by Bradley[3]. Direct suspensions shadowed with metal[5,6] and pre-shadowed replicas[7] were not found to be successful for studies at high resolution. Very thin evaporated metal films, normally used in electron microscopy to enhance contrast, are then found to consist of very small particles which confuse rather than reveal much of the fine detail in the specimen. The type of structure produced by shadowing is in agreement with that found by Sennett and Scott[8].

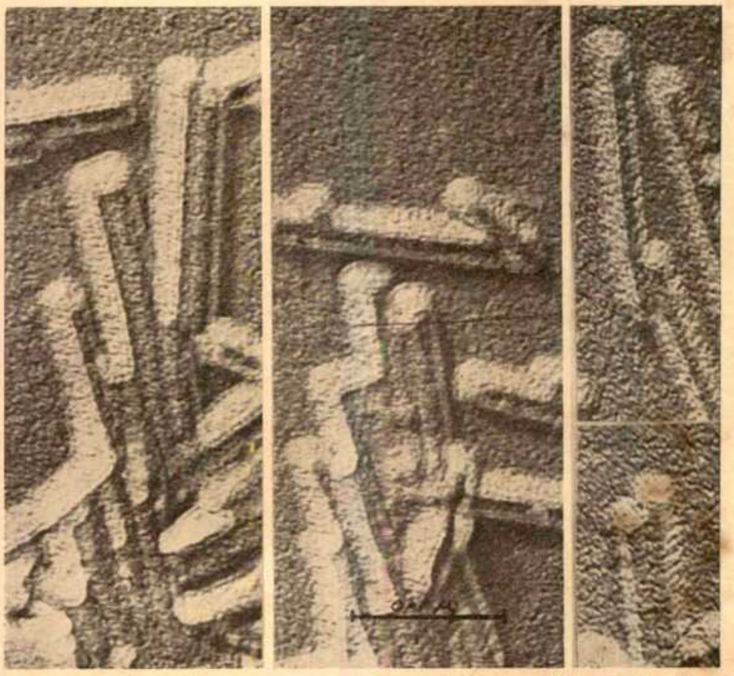

Fig. 2. Carbon replica of tobacco mosaic virus rods lying parallel to the direction of evaporation, showing 'herring-bone' structure and also longitudinal structure. (Original magnification × 40,000; reproduced at × 200,000.) Scale = 0·1μ

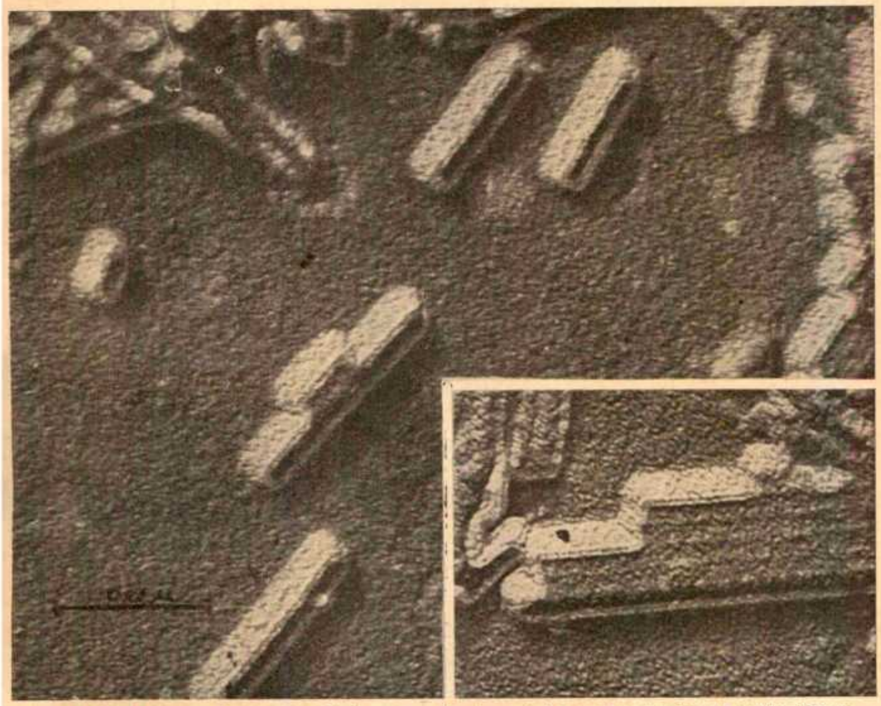

Fig. 1. Single-stage carbon replica of tobacco mosaic virus rods lying across the direction of incidence of the evaporated carbon, showing longitudinal structure along the rods. (Original magnification, × 40,000; reproduced at × 200,000.) Scale = 0·1μ

The replicas were examined in the electron microscope at instrumental magnifications of × 40,000 and × 80,000. In Fig. 1, where numerous rods lie across the direction of incidence of the evaporated carbon, a longitudinal structure is visible running the full length of the virus rod. The same longitudinal structure is also resolved in Fig. 2, in rods lying parallel to the direction of incidence of the carbon. Fig. 2 also shows a 'herring-bone' structure in some of these rods. Measurements made from prints enlarged to × 400,000 gave a mean value of 46 A. for the axial repeat-distance of this structure, which is almost exactly double that of the pitch of the helix deduced from the X-ray data. In the few rods which show evidence of helical structure, the angle of advance was found to be between 80° and 85°, as compared with the value of 82·5° required by the model proposed by Franklin[1]. The width of the rods, measured in regions of close packing, is found to be 150 ± 5 A.

One of the most striking features is the angular appearance of the virus rod in cross-section, suggesting a hexagonal form with a groove at the corners. A series of electron micrographs through the focus has been taken to ensure that the pronounced ridges are not due to electron optical fringe effects. Mixed preparations of tobacco mosaic virus and turnip yellow mosaic virus have been examined under the same conditions. These observations showed that the structures described were confined to the tobacco mosaic virus.

This work has been carried out with the assistance of a grant from the Agricultural Research Council, to which we are indebted. We also wish to thank Dr. R. Markham for supplying some of the tobacco mosaic virus and for several valuable discussions.

Fine Structure of Tobacco Mosaic Virus

ALTHOUGH tobacco mosaic was one of the first viruses to be examined in the electron microscope, electron microscopy has failed to reveal any fine structure, even though it has been repeatedly looked for[1,2], especially since the introduction[3] of metal shadow casting in 1945.

The present findings result from a study directed at increasing the visibility of macromolecules in the electron microscope, and in particular from evaporating heavy metal at angles (with respect to the substrate) close to 0°.

A sample of the *U*1 strain[4] of tobacco mosaic virus, buffered to *p*H 6·8 in cacodylic acid, was diluted with distilled water to a concentration of 0·005 mgm./ml. and then sprayed on to the collodion-covered convex face of a plano-convex lens of 250 mm. radius of curvature. Thorium was evaporated at a pressure 10^{-4} mm. of mercury from a tungsten filament, the height of the lens being adjusted so as to give grazing incidence of the metal beam near the pole of the lens.

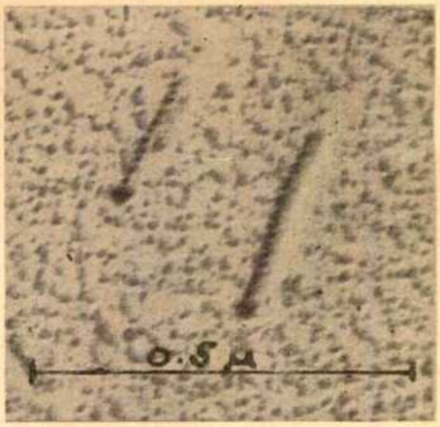

Fig. 1. Electron micrograph of tobacco mosaic virus (*U*1 strain) air-dried on collodion substrate and shadow-cast with thorium at low angle. The direction of shadowing is from lower left. (× 100,000)

The collodion was then stripped from the glass and mounted on 200-mesh copper screens. This technique offered a range of incidence angles in the neighbourhood of 0°, the exact angle depending on the original position on the glass surface.

At angles of incidence near 0°, tobacco mosaic rods which lay perpendicular to the direction of the incoming beam appeared normal, with thorium piling up on the incident side. Rods which lay parallel to the incoming beam, however, showed a periodic density variation along the long axis, in addition to the metal cap on the end which would be expected (Fig. 1). The visibility of the striations decreased as the orientation of the rod varied from parallel to perpendicular. The visibility of the striations was also very sensitive to shadowing angle, the striations disappearing completely for angles greater than approximately 5°.

The period of the density fluctuations along the rod axis, as measured from a number of rods, averaged 136 A. As seen in Fig. 1, the individual striations are not perpendicular to the long axis of the rod, and the net effect is that of a right-handed helix.

Franklin and Klug[5] have recently published X-ray evidence for the existence of a helical groove or helical array of protuberances on the surface of the tobacco mosaic virus rod. The X-ray data can be interpreted as showing a discontinuity 30 A. deep, with the pitch of the underlying protein. While no agreement exists on the value of the pitch, the X-ray value for depth of groove is of the same order as that deduced in this work.

From the variation in contrast as a function of shadowing angle, it can be deduced that the slope of the discontinuity responsible for the deposition of metal must be no more than a few degrees, and the height of the discontinuity is of the order 15–30 A. A simple calculation based on the shadowing angle and the amount of thorium evaporated shows that migration and crystallization of thorium atoms on the rod surface will not account for the observed effect.

Similar results for the *U*2 strain of virus have been obtained, with some differences which will be reported on more fully elsewhere.

I wish to thank Dr. A. Siegel for furnishing the tobacco mosaic virus used in this investigation, which

was supported by the U.S. National Institutes of Health.

Differences in the Chemical Composition of the Phage Nucleic Acids

IT has been known for some time that the nucleic acids of the coli-dysentery phages, T_2, T_4 and T_6, contain hydroxymethylcytosine and that the composition of their purine and pyrimidine bases is essentially identical[1]. More recently it was found in this laboratory that a hexose is present in T_4 phage[2]. This sugar was identified as glucose and was shown to be a constituent of the viral nucleic acid[3]. It was afterwards demonstrated that T_2 and T_6 nucleic acids also contain glucose and that enzymatic hydrolysates of T_2 and T_4 nucleic acids contain small quantities of the glucoside of hydroxymethylcytidylic acid[4,5]. In the present communication it will be shown that the nucleic acids of T_2, T_4 and T_6 phages differ in their content of glucose and that this hexose is attached to the acid-resistant part of nucleic acid, the apurinic acid.

The wild type (r^+) strains of T_2, T_4 and T_6 viruses were used in this study. They were grown on *E. coli B* in synthetic medium and purified by procedures already described[6]. In order to obtain the viral nucleic acids, aqueous suspensions of the phages were repeatedly frozen and thawed and then deproteinized with chloroform and octyl alcohol in presence of 1 *M* sodium chloride. The nucleic acids were precipitated with ethanol, then dialysed and dried from the frozen state.

The materials thus obtained formed viscous solutions and showed adsorption spectra characteristic of nucleic acid. Their atomic extinction coefficients ($\varepsilon(P)$ at 260 mμ) varied between 7020 and 7280. From Table 1 it can be seen that the nucleic acids derived from T_2, T_4 and T_6 phages differed slightly yet significantly in their nitrogen and phosphorus content. Colorimetric and chromatographic analyses revealed that deoxypentose as well as glucose were components of each. The purine-bound deoxypentose was determined quantitatively with diphenylamine using deoxyribose as a standard. Glucose was determined by means of the anthrone reaction. Since deoxyribose produces a colour with this reagent, absorption was measured at 620 and at 500 mμ and the content of glucose calculated according to the procedure of Knudson, Meloche and Juday[7]. The amount of deoxyribose in the three nucleic acids varied but slightly (18·8–19·8 per cent), whereas differences in glucose content were considerable. The T_2, T_4 and T_6 nucleic acids were found to contain 6·7, 8·4 and 12·0 per cent of glucose respectively. Thus, for each mole of phosphorus there was present 0·14 moles of glucose in the T_2 nucleic acid, 0·18 moles in the T_4 nucleic acid and 0·28 moles in the T_6 nucleic acid. Since each nucleic acid contained approximately 0·17 mole of hydroxymethylcytosine per mole of phosphorus[1] it is evident that the amount of glucose in the nucleic acids derived from T_4 and T_6 exceeds that of the pyrimidine. In the case of T_2 nucleic acid this amount is less.

Table 1. CHEMICAL COMPOSITION OF THE NUCLEIC ACIDS AND THE APURINIC ACIDS OF T_2, T_4, T_6 VIRUSES

	N (per cent)	P (per cent)	Glucose (per cent)	$\frac{[\text{Glucose}]}{[\text{P}]}$
T_2 nucleic acid	14·1	8·4	6·7	0·14
T_4 ,, ,,	13·8	8·0	8·4	0·18
T_6 ,, ,,	12·8	7·4	12·0	0·28
T_2 apurinic acid	5·9	9·8	7·9	0·14
T_4 ,, ,,	5·7	9·7	9·9	0·18
T_6 ,, ,,	5·2	9·0	14·0	0·27

In order to gain some information concerning the nature of the glucose linkage in the viral nucleic acids, the latter were hydrolysed with dilute sulphuric acid at *p*H 1·6 and at 37° C. After dialysis to remove purine bases, the apurinic acids were recovered by lyophilizing the residues[1].

The three viral apurinic acids showed typical absorption spectra when measured at *p*H 6·8, with maxima at 267–68 mμ and minima at 235–38 mμ; their atomic extinction coefficients ($\varepsilon(P)$ at 260 mμ) varied from 4050 to 4280. Chemical analyses revealed that each contained considerably less nitrogen and more phosphorus than the intact nucleic acids from which they were derived. The low molar ratio of N/P (1·3) indicated that on hydrolysis the bulk of the purines was split off. The content of deoxyribose and glucose was increased to 23·0–23·8 and 7·9–14·0 per cent respectively. The molar ratios of glucose to phosphorus were similar to those found in the viral nucleic acids themselves. This fact indicates that glucose is attached mainly to the acid-resistant part of the nucleic acid molecule.

From the data which have been presented, it is apparent that the nucleic acids of T_2, T_4 and T_6 phage differ from the usual nucleic acids in that they contain not only hydroxymethylcytosine but glucose as well. The amount of this saccharide in the three viral nucleic acids appears to be different. The evidence at hand indicates that glucose is bound to the apurinic part of the molecule, probably in the form of a glucoside of hydroxymethylcytidylic acid. Where more glucose than hydroxymethylcytosine is present, it is apparent that part of the sugar must be linked to the pyrimidine in a different manner, perhaps as a disaccharide. The confirmation of this must await further experimentation.

Since this communication was submitted for publication, a report describing variations in the glucose–deoxyribose ratio in r^+ and r variants of *T*-even phages has appeared[8].

Physical Basis of Insect Repellency

The physical basis of insect repellency being unknown, the search for new repellents has had to be conducted on an essentially hit-or-miss basis. With the accumulation of evidence that the odours of substances may be correlated with the low-frequency, fundamental vibrations of their molecules[1], it seemed worth while to examine the absorption of some typical insect repellents in the far infra-red part of the spectrum.

The following commercial insect-repellent substances were available: dimethyl phthalate, indalone, 2-ethyl hexanediol-1,3, benzyl benzoate, *n*-propyl-N,N-diethyl succinamate and butoxy propylene glycol. In order to increase the statistical weight of the results, additional substances were chosen on the basis of ready availability from the extensive list of repellent chemicals published by Morton, Travis and Linduska[2].

These workers tested 6,241 chemicals as mosquito repellents. The tests were made by covering the forearms of test subjects from wrist to elbow with the chemical or with a treated cloth, and then exposing them in cages containing some thousands of unfed mosquitoes (*A. aegypti*). The substances were graded on the basis of the duration of protection they afforded, the most effective substances being placed in group 4 and the least effective in group 1. This method of screening could only have been approximate, and individual substances may now and then have been wrongly classified (benzyl benzoate, for example, was placed in group 1 and has since found application as a repellent); yet a random selection of compounds from group 4 may be expected to consist mainly if not entirely of repellents, and a similar selection from group 1 will be mainly non-repellent.

Fourteen substances showing grade 4 repellency were collected from available chemical stocks to give a test set of twenty repellents altogether. A control group of twenty non-repellent (group 1) substances was also assembled from available chemical stocks. Infra-red absorption curves were recorded in the region from 700 to 400 cm.$^{-1}$ using a Perkin-Elmer Model 21 infra-red spectrophotometer equipped with a potassium bromide prism and a linear wave-number cam. Liquids were examined as received. Solids were usually examined as mulls in 'Nujol' (which is transparent in this region) or, in a few cases, as compressed films with potassium bromide.

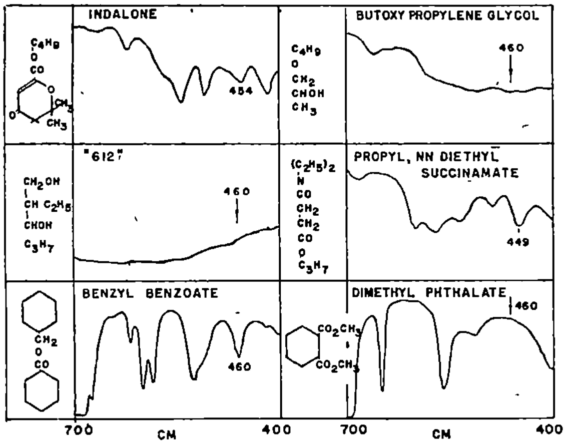

Fig. 1

The absorption curves of the six commercial repellents are shown in Fig. 1. The results exhibit a striking correlation in the part of the spectrum near 460 cm.$^{-1}$. Of the whole group of twenty repellent substances, thirteen have peaks between 449 and 471 cm.$^{-1}$, three of the remainder show strong continuous absorption in this region, and three have nearby broad bands which overlap this region. Of the non-repellent substances, only one has a peak between 449 and 471 cm.$^{-1}$ and the rest with few exceptions show very little absorption in the neighbourhood of 460 cm.$^{-1}$.

The only marked exception in the repellent group is dimethyl phthalate, the repellent properties of which are well known; it has no absorption peak near 460 cm.$^{-1}$. This substance is, however, one of the few members of the repellent group the structure of which is sufficiently symmetrical for certain vibrational modes to be inactive in the infra-red. It may be significant that the Raman spectrum of this substance[3] has a line at 230 cm.$^{-1}$.

Thus the conclusion seems inescapable that the physical basis of mosquito repellency is a molecular vibrational mode capable of giving rise to infra-red absorption or Raman scattering near 460 cm.$^{-1}$ (or 21·7μ). Whether other species of insect are repelled by molecules exhibiting this or some other characteristic frequency is not yet known. The practical value of these results in screening new substances for mosquito repellency will be evident at once. Their bearing on the general problems of olfaction is to lend support to the hypothesis that the low-frequency vibrations of molecules provide the physical basis of their odours. A discussion of the mechanism whereby such vibrations may be able to trigger nerve discharges will be published elsewhere.

I thank the Van Ameringen Co., Firmenich, Inc., and Dr. Hubert Martin for the gift of samples.

Effect of Fungicides on Fungus Enzymes

Evidence has already been obtained to show that an important mechanism of the toxic action of fungicides is the inhibition of fungus enzymes. Copper and mercury are known to inhibit different systems, including those concerned with carbohydrate metabolism[1]. Rich and Horsfall[2] have investigated the action of phenols and quinones upon polyphenol oxidase, while Owens[3] has examined the effect of organo-sulphur compounds, phenols, quinones and metal compounds upon amylases, polyphenol oxidase and catalase. Attention has been given to the mode of action of different types of derivatives of thiocarbamic acid. Weed, McCallan and Miller[4] found that ferbam (ferric dimethyldithiocarbamate) inhibited urease, whereas nabam (disodium ethylene bisdithiocarbamate) had little effect. Sisler and Cox[5] attribute the toxicity of thiram (bis(dimethylthiocarbamoyl) disulphide) largely to the inhibition of the enzyme triosephosphate dehydrogenase. The activity of 8-hydroxyquinoline has been ascribed[6] to chelation with metal ions essential for enzyme action. Owens[7] has shown that captan (N-trichloromethylthio-*cyclo*hex-4-ene-1,2-dicarboxyimide) prevents the assimilation of inorganic phosphate, and Hochstein, Cox and Sisler[8] have reported that this compound affects cellular metabolism by blocking key decarboxylation reactions.

We have examined the effects of four fungicides upon enzymes of *Sclerotinia laxa* Aderh. and Ruhl., the fungus responsible for the blossom wilt disease of fruit trees. The fungicides used were captan, copper (as sulphate), lime sulphur and *o*-phenyl phenol. Cultures of the fungus were grown on dextrose–peptone–phosphate liquid medium, in which the fungicides were incorporated in amounts found by trial to produce approximately 50 per cent inhibition of growth after incubation at 25° C. for seven days. The fungus felts were washed with water and frozen at −17° C. for 12 hr. or more before grinding them with three times their weight of cold 0·1 *M* phosphate buffer, *p*H 7·5, in a mortar and then in a Ten Broeck glass macerator at 0° C. The homogenate was centrifuged at 2,000 *g* for 10 min. at 4° C. The cell-free extracts were dialysed for 12 hr. against the buffer in which they were prepared, so as to reduce the endogenous rates of the enzymes examined. The following enzymes were determined in 'phosphate' extracts: catalase, peroxidase, cytochrome *c* oxidase and reductase, diphosphopyridine nucleotide oxidase (diaphorase), succinic, *iso*citric and glutamic dehydrogenases, fumarase and polyphenol oxidase. Tris(hydroxymethyl)aminomethane (0·1 *M*, *p*H 7·5) extracts of the felts were used for the determination of hexokinase, aldolase and alkaline phosphatase.

Protein was determined in the extracts by the method of Folin, and enzyme activities were expressed in units per milligram protein (specific activities). The results are shown in Table 1.

Lime sulphur markedly depressed the iron enzymes, but showed little further effect beyond a stimulation of aldolase. Copper treatment appreciably reduced aldolase and fumarase and stimulated diphosphopyridine nucleotide oxidase and hexokinase. Treatment with captan enhanced diphosphopyridine nucleotide oxidase and depleted glutamic dehydrogenase. *o*-Phenyl phenol depressed the flavoprotein diphosphopyridine nucleotide oxidase system.

It is interesting to note that while copper depressed cytochrome *c* oxidase, it exerted a compensating effect by stimulating the alternative diphosphopyridine nucleotide oxidase system for electron transport. The reverse, however, is seen with *o*-phenyl phenol, where a reduction in the activity of diphosphopyridine nucleotide oxidase was accompanied by an increase in that of cytochrome *c* oxidase.

Table 1. EFFECT OF FUNGICIDES ON ENZYMES OF *S. laxa*

Enzyme	Captan	Copper	Lime sulphur	*o*-Phenyl phenol
Catalase	+	−	− −	−
Peroxidase	−	0	− −	−
Cytochrome *c* oxidase	0	− −	− −	+ +
Cytochrome *c* reductase	+	−	− −	+
Diphosphopyridine nucleotide oxidase	+ +	+ +	+	− −
Succinic dehydrogenase	0	0	−	−
*iso*Citric dehydrogenase	−	−	−	0
Glutamic dehydrogenase	− −	−	+	0
Hexokinase	0	+ +	−	0
Aldolase	−	− −	+ +	0
Alkaline phosphatase	0	0	−	0
Fumarase	−	− −	−	0
Polyphenol oxidase	−	−	0	+

−, Some depression; − −, marked depression; 0, no effect; +, some stimulation; + +, marked stimulation.

Further studies may lead to a more rational selection of toxicants for the control of pathogenic fungi. The work is being extended to include other fungi and fungicides.

Antibacterial Substances in Seeds

WHILE investigating the physiology of germination, it was noted that micro-organisms occurring on the seeds of certain species proliferated rapidly during germination, whereas the seeds of some other species, germinating under the same conditions, remained sterile. It seemed obvious that certain seeds must contain and release—during germination—compounds that are able to inhibit the growth of certain micro-organisms. In order to examine this hypothesis, the antibacterial effect of seeds of several species and varieties of plants has been investigated.

To carry out these examinations the agar-diffusion method[1] seemed to be the most adequate. In a Petri dish fresh bacterium suspension was run on to a solid, 5 mm. thick bouillon agar-plate, containing 2 per cent agar at *p*H 7. After removing the excess and having dried the surface, the experimental seeds were sunk into the culture medium. As the micro-organisms to be tested have been selected from the rapidly proliferating species, a previous disinfection of the seeds that might dissolve the antibacterial compounds was unnecessary. The time of incubation was 20 hr. at 30° C. The clear zones occurring during this time indicated the presence of antibacterial compounds and their size gave information about the intensity of the effect.

Whole seeds were examined, as the natural process of germination was considered to be of chief importance. The only exceptions were the species of *Fraxinus*, the seeds of which, cut transversely, were placed on the agar plate in order to see whether the compound within the seeds inhibiting the germination[2] inhibited growth of the bacteria as well.

The behaviour of seeds not more than a year old of four hundred species and varieties of higher plants belonging to seventy families has been observed by the method above described. In every case eight bacterial strains were used as test micro-organisms. Gram-positive: *Bac. cereus* var. *mycoides*, *Bac. megatherium* 208, *Bac. subtilis* var. *panis*, *Staphylo-*

coccus aureus; and Gram-negative: *Aerobacter aerogenes*, *Erwinia carotovora*, *Shigella flexneri VI* and *Xanthomonas malvacearum*.

The seeds of thirty-six species of plants yielded positive results. In most cases the effect was selective, the diffusing compounds inhibiting the increase of only the Gram-positive bacteria. The inhibitor of the *Fraxinus* species proved effective also against most Gram-negative test micro-organisms. The effect on the Gram-positive bacteria was of similar intensity.

With *Bac. cereus* var. *mycoides*, clear zones of a diameter of more than 1 cm. were produced by the seeds of the following species: *Abies alba*, *Aristolochia clematitis*, *Geranium silvaticum*, *Hypericum elegans*, *Juniperus chinensis*, *Kniphofia aloides*, *K. hybrida*, *K. praecox*, *K. tuckii*, *K. uvaria*.

Zones of 5 mm. diameter or more: *Aristolochia fimbriata*, *Atriplex hortensis*, *A. nitens*, *Cannabis sativa*, *Chenopodium polyspermum*, *Consolida ajacis*, *C. orientalis*, *C. regalis*, *Fraxinus excelsior*, *F. pennsylvanica*, *Maclura aurantiaca*, *Pinus strobus*.

Zones of less than 5 mm.: *Amaranthus ascendens*, *Chenopodium album*, *Ch. bonus*, *Ch. urbicum*, *Kochia scoparia*, *Picea alba*, *P. excelsa chlorocarpa*, *Pinus nigra*, *Pseudotsuga douglasii*, *P. taxifolia*, *Stachis annua*, *Verbena canadensis*, *V. officinalis*.

Certain seeds—generally known to contain antibacterial compounds (*Gynocardia*, *Hydnocarpus*[3], Cruciferae[4–6])—gave no positive results in the present study. The reason is that the active compounds are located in the inner parts of these seeds and are, as a rule, released only by ferments[5,6].

The diffusing compounds observed in the present cases, except the inhibitor of the *Fraxinus* species, are localized in the seed-coat. The active substance of the seeds of *Kniphofia* species has been isolated. Isolation of active substances from other seeds has been started. The detailed results will be dealt with elsewhere.

Alternaria within the Pericarp of the Wheat Seed

In 1951, Miss Hyde[1] obtained from the basal internode (about 1–2 in. long) of flowering stems of Barsée wheat and from stems immediately below the inflorescence, under aseptic conditions in culture plates, *Alternaria tenuis* in 40 and 43 stems out of 70. In 1953, I[2] published a note on the apparent symbiotic nature of *Alternaria tenuis* within the pericarp of some local wheat seeds. Since then, in the winters of 1953 and 1954, I carried out aseptic culture of our common wheat seeds within two sterilized glass chambers where aseptic seedlings from malt agar tubes were planted on sterilized manured soil, making provision for circulation of pure air which was sucked through cotton-wool in glass tubes by means of a water tap suction pump, and sterilized water, passing through a horizontal glass tube inserted through an air-tight hole on the chamber wall, dropped direct on the seedlings half an hour every day for two and a half months from early November. The two glass chambers were quite similarly fitted. In one glass chamber aseptic seedlings were prepared in the following way: wheat seeds were surface-sterilized with 0·1 per cent mercuric chloride for six minutes, washed three times in sterilized distilled water and planted in malt-agar tubes where they germinated into seedlings in the course of four days. In the other glass chamber, *Alternaria tenuis* was eliminated from the aseptic seedlings in the following way: wheat seeds in sterilized water in a test-tube were exposed to a temperature of 53·5°–54° C. in a water-bath for ten minutes to kill *Alternaria* within the seed coat; they were then cooled, surface-sterilized with 0·1 per cent mercuric chloride for six minutes as before, washed three times in sterile distilled water and planted into malt-agar tubes for germination into seedlings. The temperature of two glass chambers was 10–15 degrees higher than that of the laboratory and they were usually in a very humid condition during the experiment. In the course of a month and a half it was found that the growth of plants and number of tillers under sterilized conditions in the glass chamber where *A. tenuis* was not eliminated were more vigorous and more numerous than those of the plants in the chamber where the *Alternaria* was eliminated by hot water treatment. Thus, the presence of *Alternaria tenuis* within the wheat plants in this case seems distinctly helpful.

Discussing the black point disease of wheat in the United States, Hansen and Christensen[3] in 1953 held from replicated tests that "*Alternaria* infection does not cause any appreciable reductions in stand or any seedling blight and that *Alternaria* has little, if any, deleterious effect on the value of the infected grain for seed". Their final conclusion was that "*Alternaria*, although the most prevalent fungus, was either non-pathogenic or weakly pathogenic and never caused seedling blight of wheat in the greenhouse or field".

But in February 1955 there was a report[4] of severe leaf spot disease of 'durum' wheat by an *Alternaria* sp. from Cuttack (Orissa), Central Rice Research Institute; the brown spotting on leaves, which from a distance looked like rust, was so extensive that ultimately the yield was considerably reduced, leading to almost a complete failure of wheat crop. In this case the disease was strictly confined to 'durum' wheat and common varieties of wheat were free from it. A similar outbreak of severe leaf spot disease of 'durum' wheat by *Alternaria* sp. was noted by Mehta[5] in 1950 from the Research Farm of Kanpur, Uttar Pradesh of India. He established the parasitic nature of that *Alternaria* sp. by inoculation experiment on 'durum' variety with pure culture of his isolation of *Alternaria* from leaf-lesions of the wheat. Mehta held that the disease was seed-borne. Some data, however, are lacking, if the seeds sown in the field in both cases originally harboured the same *Alternaria* sp. within the seed coat of 'durum' wheat, and the species of *Alternaria* here has not been determined. In this connexion it may be remarked that no sharp lines of demarcation can be drawn between symbiotic interrelationship and antagonistic effects and that symbiosis and parasitism (antagonism) have much in common both physiologically and morphologically; the one may be converted into the other by a comparatively slight change of circumstances.

Studying spore production by *Helminthosporium avenae*, Grainger[6] found "no correlation between spore-liberation and general climatic conditions, i.e., temperature, relative humidity and wind velocity", ontrary to the experience of plant-pathologists in any plant diseases. He suggests that as the factor annot be climatic in this case, "an investigation of onditions within the host plant itself is most likely o provide an explanation". I think in wheat rust imilar study of conditions of growth within the wheat lant may yield some clue to the main problem of radication. So far, at wheat rust study centres no ttention in this direction seems to have been paid.

Effect of Crowding during the Larval Period on the Determination of the Wing-form of an Adult Plant-hopper

The effect of crowding on the physiological and orphological characters of larvæ or adult has ttracted much attention. Comprehensive reviews ave been published by Allee[1], and recently by hauvin[2]. The latter distinguished two categories in he general effect of crowding, "l'effet de masse" and l'effet de groupe", which had been proposed by rassé. Bonnemaison[3], in his studies on the factors ffecting the appearance of the winged form in phids, and Badonnel[4], working on the complete evelopment of the wings in Psocoptera, found that he most important effect of crowding occurs during he developmental period.

I am investigating the factors determining the ing-form, macropterous or brachypterous, of plant-oppers, and I have found that crowding during he larval period plays an important part in the etermination of wing-form in the brown plant-opper, *Nilaparvata lugens* Stål.

The brown plant-hopper is a serious pest of the ce plant in Japan. The macropterous form has ormal fore- and hind-wings; but the brachypterous rm has the fore-wings of half the normal length d rudimentary hind-wings, and this form conquently cannot fly. Macropterous males and females ppear at first in the paddy fields in early summer. rachypterous females appear afterwards and inrease in number during the summer and autumn. y late autumn, when the rice plants ripen, the acropterous form becomes prevalent again. Brachyterous males appear in late summer and autumn ut are less frequent than females.

Larvæ were put into test-tubes (2 cm. in diameter nd 17·5 cm. in length) within 24 hr. of hatching, ith a leaf blade of rice plant in each for food. A w drops of water were poured into each tube. Food d container were renewed at intervals of 1, 2 and days in each series of density.

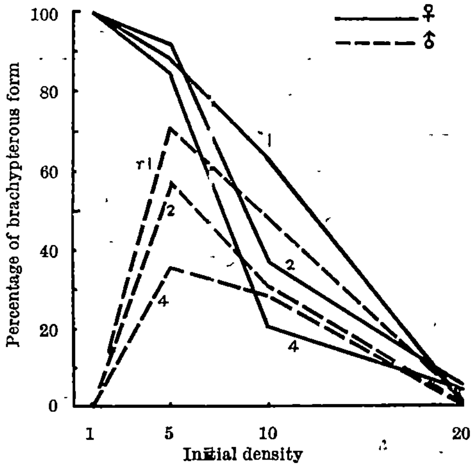

Fig. 1. Percentage of the brachypterous form of both sexes resulting from a breeding experiment in which the initial density and interval of renewal of the food and container were varied

The result is shown in Fig. 1. At the lowest density e figures differ extremely with sex; all emerged males are brachypterous and males are macroterous. With increase of density, the percentage of e macropterous females increases and reaches almost 00 per cent at a density of 20. On the other hand, in the males, the brachypterous form appears in the middle range of density. At greater densities, the macropterous form increases again with the density in parallel with the females. Therefore, the optimal density for the appearance of the brachypterous male can be determined.

On the other hand, the effect of freshness of food and change of container has also to be appreciated. When the interval of renewing food and container is prolonged, the appearance of the macropterous form is accelerated in both sexes. This effect is most clearly shown in the middle range of density. It seems probable that the larvæ are at the critical state for determining their form at that density.

The larval period of the various forms is shown in Table 1; that for the brachypterous form of both sexes is shorter than that for the macropterous form. The former shows a rather constant period even at high densities, whereas that of the latter shows a lengthening effect. Examined in more detail, it is found that at the density of 5 at which the brachypterous male appeared in highest proportion, this form is the group having the shortest period of larval development. This larval period is shorter than that of the macropterous male, which appeared exclusively at a density of 1. This acceleration of

larval development seems to be due to mutual stimulation among the members in a tube.

Other experiments have shown that the wilting of the host plant produces the macropterous female without the effect of crowding, accompanied by the considerable elongation of the larval period. This fact seems to be responsible for the prevalent appearance of the macropterous female in the field in late autumn.

Various solutions of salts were used instead of water in the test-tubes for examining their effectiveness for the determination of the various forms. The concentration of each solution was 0·05 mol. The initial density used was 5. Food and container were renewed every day and no wilting of the leaf blade was observed, except when copper sulphate solution was used; in that case all larvæ died in a few days (Table 2). These solutions show, more or less, the effectiveness on the production of the macropterous form in both sexes. Parallel decrease in the percentage of the brachypterous form is clearly shown in both sexes, though the absolute figures for the brachypterous females in each treatment always exceed those of males.

The observations lead to the following conclusions.

(1) Low density under favourable conditions of food supply during the larval period is necessary for the appearance of the brachypterous female. On the other hand, optimal density under favourable conditions of food supply produces the brachypterous male. The mechanism of the different responses of the sexes to crowding remains to be found.

(2) Optimal crowding accelerates the development of the larvæ, and this fact seems to be responsible for the mechanism inducing the appearance of the brachypterous male at the optimal density.

(3) Wilting of the host plant, overcrowding, contamination due to crowding and solutions of several salts have the effect of producing the macropterous form, and this effect is followed by lengthening of the developmental period of the larvæ subjected to these conditions.

(4) Factors causing the appearance of the brachypterous form must be studied in parallel with those leading to the appearance of the macropterous form, especially the males, as shown in the present communication.

An Apparent Reaction of Fish to Linear Accelerations

IT has been reported that fish do not appear t react to rectilinear accelerations[1]. However, the have the sense organs to detect such movements ; th otolith organs of the thornback ray are sensitive t linear translations in all three planes of space[2] an teleosts take up compensatory positions when subjected to centrifugal force[3]. Some experiments wer therefore made to re-examine the reactions of fish t rectilinear accelerations, blinded minnows, goldfis and naturally blind cave characins, *Anoptichthy jordani*, being used in the preliminary observation The fish were placed in an enclosed 'Perspex' tank completely filled with water, and mounted on rubber-wheeled chassis. They appeared to turn abou when the tank was accelerated along a bench b hand.

The reactions of blind goldfish were then studie in a more quantitative manner. A fish was introduced into an enclosed 'Perspex' tank, 60 cm. long 30 cm. × 15 cm. in section, which was filled with wate The tank was housed in a welded angle-iron chassi fitted with flat rubber-tyred wheels running on 4-m. long railway made from ¾-in. steel rod firml attached to sleepers. The chassis was attached to rope which ran over two pulley wheels so arrange that the vertical fall of heavy weights would accelera the tank horizontally along the railway. When th weights hit the ground, the forward movement of th tank was checked by a rope attached at one end t a wall and at the other to the tank by a short lengt of rubber tubing. A range of accelerations an decelerations was covered by varying the weight and the forward run of the tank. The movemen of the tank relative to the ground and that of th fish relative to the tank was recorded by a 16-mm ciné camera mounted vertically above the railway Releases were only made when the fish was in mid water and well clear of the sides of the tank, an when it was swimming more or less in a straigh line either with or against the movement of the tank

The results showed that blind goldfish would tur about when suddenly stopped going forward, or whe suddenly started backwards, but not when starte going forwards or when stopped going backwards An analysis of two typical results is given in Figs. and 2. The orientation of the fish is given relativ to the longitudinal axis of the tank, a bearing of 0 indicating that the fish was facing in the directio of the tank's movement. In Fig. 1 the tank wa released so that the fish was accelerated backward and it turned about. When the tank slowed down the fish was decelerated while travelling forwards an turned again. In Fig. 2 there was no reaction to a acceleration when the fish was going forward, bu the fish turned on deceleration. A positive reactio was thus only observed when the otolith organs wer displaced anteriorly, as indicated diagrammaticall in the figure.

The threshold acceleration to induce a reactio was high, positive results being obtained only wit accelerations or decelerations greater than 160-200 cm./sec./sec. In both Figs. 1 and 2 it will b seen that the tank recoiled after its forward movement was checked. In some experiments a fish wa observed to turn both when the tank slowed dow and when the recoil movement slowed down.

While there is an apparent reaction of blind goldfis to linear accelerations, the results do not show con-

Reactions of Blind Goldfish to Accelerations

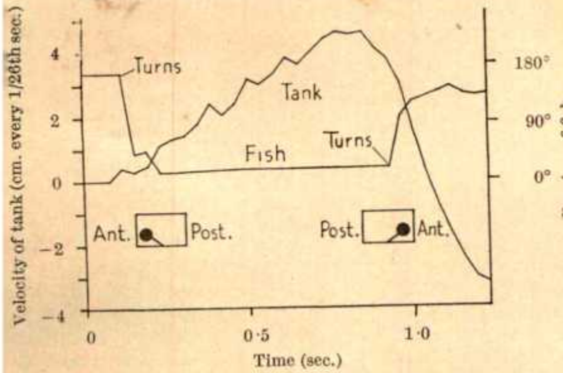

Fig. 1. Fish accelerated backwards. Acceleration, 170 cm./sec.^{2}; deceleration, 364 cm./sec.^{2}.

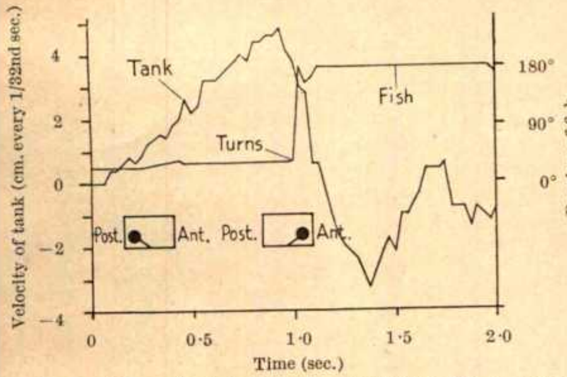

Fig. 2. Fish accelerated forwards. Acceleration 176 cm./sec.^{2}; deceleration, 710 cm./sec.^{2}.
The fish only appears to turn when the otolith organs are displaced anteriorly

clusively that the stimulus to which the fish responds is labyrinthine in origin. With these particular fish it was not possible to release the tank when they were at right angles to its line of movement, as they swam for the most part up and down the length of the tank. Furthermore, unless the ciné camera is mounted on the chassis itself, it is not possible to detect movement of the water relative to the fish, or to study the nature of any eddies or swirls that might be set up in the tank, all of which might stimulate the fish. In the early stages of this work, it was thought unwise to risk the camera in this way; but further experiments with other fish are now planned to look into these points.

The Basement Membrane – Elastica System of the Dermo-Epidermal Junction

Reports (based on electron microscopy)[1] of the presence of a subepidermal basement membrane in human skin conflict with the orthodox histological view[2] that dermo-epidermal adhesion is effected by an interlocking of the subepidermal 'reticular fibres' with the foot processes of the basal cells, and that no basal membranous structure apart from this layer of reticulin exists.

A more satisfactory account of the stabilizing mechanism of the human dermo-epidermal junction can now be offered.

The basic dye alcian blue used in buffered aqueous solutions of *p*H 1·2–2·0 will stain certain tissue structures which are not generally basophilic even at higher *p*H levels. These structures comprise collagenous and reticular tissue, and various basement membranes (for example, subepidermal, vascular sub-endothelial, glomerular, renal tubular); and while previous treatment with testicular hyaluronidase prevents staining of the fibro-reticular tissue, basement membrane staining is unaffected. These results may indicate the presence of two chondroitin sulphate – protein complexes, one sensitive and the other resistant to hyaluronidase, like those isolated from rabbit skin[3]. The subepidermal basement membrane is also morphologically distinct from subepidermal reticulin; it appears as a delicate continuous tightly wrinkled band which is regular in thickness and discrete, whereas the reticulin forms a coarser interrupted layer of variable thickness which merges on its deep aspect with the fine dermal collagenous tissue.

Basement membranes are usually found in close association with reticulin; but in other respects (discreteness, optical homogeneity, apparent tenacity) basement membranes seem to have more in common with elastic tissue and even stain as elastica in certain sites (for example, around sweat glands).

It has been found that in tissue sections treated with the 'Mallory bleach', alcian blue will reveal certain additional tissue structures, some keratinous and others elastic. The elastic group comprises the sheaths of all those relatively coarse elastic fibres and laminæ demonstrable by recognized methods together with other very fine membranes and fibres, which in sections counterstained with orcein are often clearly continuous with the coarser fibres or their sheaths. In particular, the thin elastic fibres, which fan out as branches of the papillary layer of the dermal elastic plexus and run up towards the epidermis, are seen to consist of a brown orcein-

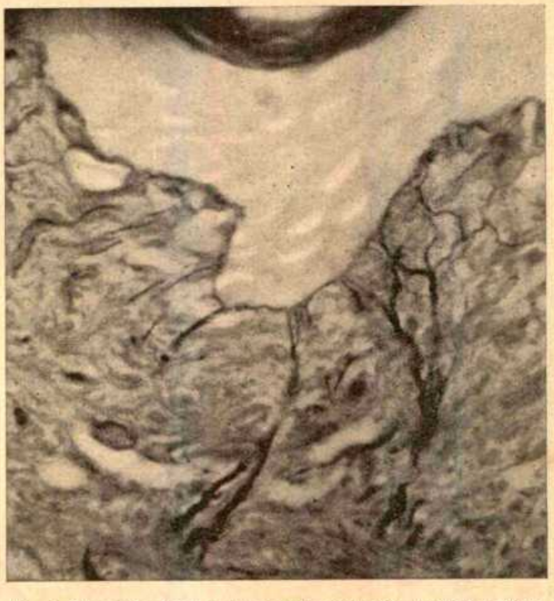

Fig. 1. The subepidermal basement membrane – elastica system. Hyaluronidase; permanganate bleach; alcian blue, *p*H 1·2 orcein. × 870

stained core (which tapers away into invisibility before the dermo-epidermal junction is reached) and of a blue sheath, which terminally remains visible as a delicate band and carries on to fuse with the blue subepidermal basement membrane.

Thus it appears that the epidermis is attached to the corium by continuity of the dermal elastic plexus with the subepidermal basement membrane, which itself must either be cemented to, or actually incorporate, the cell membrane of the inferior surface of each basal cell.

Finally, as basement membranes stain more strongly with alcian blue if the bleaching procedure is first performed, they may also contain that elastic tissue component which binds alcian blue after oxidation by permanganate. Basement membranes and elastica may form a morphological and chemical continuum analogous in some ways with the reticulin–collagen system.

Demethylation of Dimethylnitrosamine in Rats and Mice

Dimethylnitrosamine is a powerful liver poison and carcinogen[1,2], the mode of action of which is being studied in these Laboratories. As part of this programme, we have investigated the metabolic products from rats and mice using (^{14}C) dimethylnitrosamine[3].

From both rats and mice the main radioactive product is expired carbon dioxide. Thus 50 mgm. of dimethylnitrosamine/kgm. were injected subcutaneously into a mouse, and 6 hr. after injection 65 per cent of the injected carbon-14 was recovered as expired carbon dioxide. The carbon-14 recovered as carbon dioxide from rats injected at the same dose-rate is shown in Table 1. About 40 per cent is recovered in the first 8 hr., after which only trivial amounts are expired. The remainder of the carbon-14 appears to be fairly evenly distributed in the tissues at the end of the experiment, except for some 7 per cent which appears in the urine.

Table 1. Percentage of Total Carbon-14 injected into Rats recovered as Expired Carbon Dioxide

Time (hr.)	0·5	1	2	4	8	12	24
Per cent recovered	1·1	4·1	11·3	29	41	42	45
	0·9	3·3	10·5	21	37	42	44·4

These results indicate that dimethylnitrosamine is demethylated, presumably via formaldehyde, which would explain the expiration of much of the carbon-14 and the very general distribution of the remainder. The metabolism is thus closely analogous to that of the several N-methyl substituted aminoazobenzenes studied by Miller *et al.*[4].

The rapidity with which dimethylnitrosamine is metabolized makes it necessary to consider the possibility that the biochemical lesion is produced by a metabolite, and not by dimethylnitrosamine itself. The first signs of histological damage[1] to the liver have been observed only at a time when the degradation of dimethylnitrosamine is practically complete, which is not inconsistent with such a hypothesis.

It is hoped to publish this work more fully elsewhere.

Active Secretion of Sodium Ions from Isolated Sodium-rich Skeletal Muscle

The isolated sartorius of the frog, when immersed in Ringer fluid with normal potassium content, loses potassium and gains sodium rather rapidly at room temperature[1]. This also occurs at 0° C., but at a slower rate, the gain of sodium being greater when potassium-free Ringer is used[2]. When this potassium-free Ringer fluid has the same average inorganic composition as frog plasma[1] with a sodium content of 104 mM, the change in muscle sodium overnight is from its normal content of 24 m.equiv./kgm. to 47 m.equiv./kgm. (the average change in weight being only $-1·2$ per cent). If companion muscles are similarly treated and then immersed at room temperature for 2 hr. in similar fluid containing 10 m.equiv. potassium / litre, but the same concentration of sodium, there is no appreciable excretion of sodium. Steinbach's conclusions[3] to the contrary have been shown to depend very largely, if not altogether, on a faulty statistical procedure.

Similarly, if the potassium-free fluid contains 120 m.equiv. sodium/litre and the re-immersion fluid has the same sodium concentration but 10 m.equiv. potassium/litre, there is no net excretion after two hours[4].

Confirming the observations of Desmedt[5], on the other hand, we found that if the potassium-free Ringer fluid contained 120 m.equiv. sodium/litre and the companion muscles are re-immersed in fluid containing 104 m.equiv. sodium/litre with 10 m.equiv. potassium/litre, there is a marked excretion of sodium, far beyond what could be explained simply by passive diffusion from interspace fluid or injured fibres.

The magnitude of the changes are shown in the accompanying diagram (Fig. 1, *A*, *B* and *C*). The heights of the columns express the average sodium content of the fibre water. In calculating this concentration, an effective interspace volume of 0·13 litre per kilogram muscle is assumed[1]; also an additional 8 m.equiv. of sodium is considered as held in some external fibre region[4]. The total sodium external to the fibre water and represented as m.equiv./kgm. muscle is thus approximately 20 per cent of the external sodium concentration. (For the relative changes described here it makes no essential difference whether the above procedure is adopted or whether one regards the total sodium minus the interspace sodium as existing in the fibre water.)

The number of experiments and muscles used in Fig. 1 is as follows: *A* (120/120) 12 experiments,

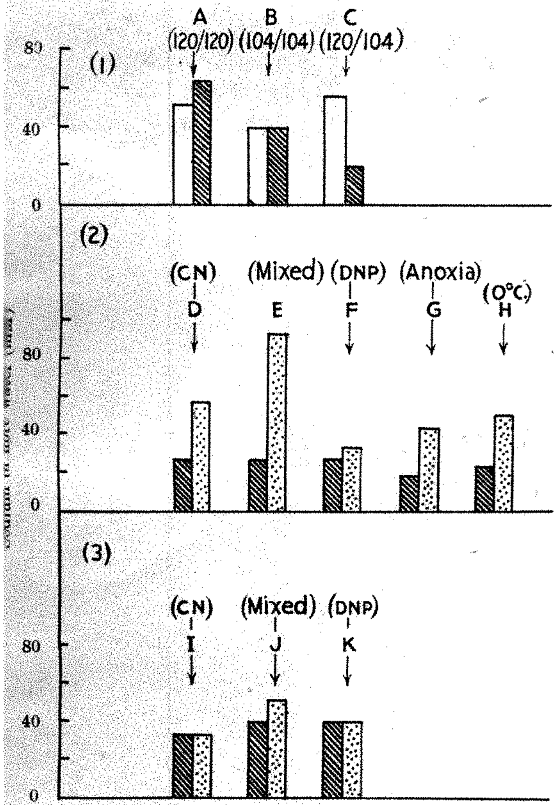

Fig. 1. (*A*) (120 : 120): Muscles immersed in potassium-free Ringer–Conway fluid (containing 120 m.equiv. sodium/litre) and reimmersed at room temperature for 2 hr. in similar fluid containing 120 m.equiv. sodium/litre and 10 m.equiv. potassium/litre. (*B*) (104 : 104): As in (*A*); the first and second fluids containing 104 m.equiv. sodium/litre and 10 m.equiv. potassium/litre. (*C*): (120 : 104): As in (*A*); the second fluid containing 104 m.equiv. sodium/litre and 10 m.equiv. potassium/litre

Fig. 2. (*D*): As in (*C*); one second immersion fluid containing 2 mM cyanide. (*E*): As in (*C*); mixed inhibitors (cyanide, 2.4-dinitrophenol and iodoacetate, each 5 mM) in one second fluid. (*F*): As in (*C*); 2.4-dinitrophenol (2 mM) in one second fluid. (*G*): As in (*C*); one second fluid free of oxygen. (*H*): As in (*C*); one second fluid at 0° C.

Fig. 3. (*I*): As in (*B*); cyanide (2 mM) in one second fluid. (*J*): As in (*B*); mixed inhibitors in one second fluid. (*K*): As in (*B*); 2.4-dinitrophenol (2 mM) in one second fluid

muscles; *B* (104/104) 51 experiments, 306 uscles; *C* (120/104) 55 experiments, 330 muscles. he symbol 120/120 signifies that the sodium connt of the potassium-free Ringer was 120 mM, as so that of the second immersion fluid, and similarly ith the other symbols.)

The considerable fall of muscle sodium in *C* is ery striking and such excretion we have found variably under these conditions. The active nature this excretion involves metabolic energy, as is own by the effect of inhibitors (Fig. 2). The contions were as in Fig. 1*C*, that is, immersion in e potassium-free Ringer fluid containing 120 .equiv. sodium/litre and re-immersion in 104 m.equiv. dium/litre with 10 m.equiv. potassium/litre. The tched columns give an average sodium content ter 2 hr. of the second immersion without inhibitor. will be seen from Fig. 2*D* that when 2 mM anide is present in the re-immersion fluid, there is nsiderable inhibition of the sodium excretion, the vel after 2 hr. being practically unchanged with spect to the muscle content after overnight imersion (13 experiments, 78 muscles). Fig. 2, *G* and show the effect of anoxia and of 0° C. (4 experiments in each, 48 muscles). It will be seen that there is considerable inhibition here also and very little, if any, active excretion. Fig. 2*F* shows the effect of 2.4-dinitrophenol inhibition (10 experiments, 60 muscles) and is of particular interest because, although the inhibitor is in 2 mM strength, its effect is very slight. Fig. 2*E* shows the effect of 5 mM cyanide, 5 mM 2.4-dinitrophenol and 5 mM iodoacetate present together (20 experiments, 120 muscles). In this case, not only is there no active excretion, but there is an increased uptake of sodium, possibly due to some degree of damage to the membranes.

The series in Fig. 3 are in striking contrast to these results. In these experiments, the re-immersion fluid contains the same sodium content as the potassium-free Ringer, namely, 104 m.equiv. sodium/litre. It will be seen that 2 mM cyanide has no effect (13 experiments, 78 muscles), neither has 2.4-dinitrophenol (10 experiments, 60 muscles). Also the mixed inhibitors have a comparatively small effect, the sodium content being somewhat increased (20 experiments, 120 muscles).

The results shown in Figs. 1*A*, 1*B*, 3*I*, 3*J* and 3*K* are quite in accordance with the results of Keynes and Maisel[6], and although these showed a considerable flux of sodium-24 across the membrane, the above results suggest that such fluxes are largely, if not entirely, explained by exchange diffusion as described by Ussing[7].

The sodium content of the muscles has been expressed on the weights after the first immersion. If one considers here that the active net extrusion of sodium from sodium-rich muscles depends on the presence of oxygen and is practically completely inhibited by cyanide (2 mM) but very little, if at all, by 2.4-dinitrophenol (2 mM), it is in full accord with what one would expect from the action of a redox pump[8].

In a recent communication in *Nature*[9], Shaw and Simon reported results of experiments in which sodium-rich muscles were immersed in Ringer fluid, diluted 1 : 1 with isotonic glucose solution, and sodium-levels were expressed in a somewhat similar manner to the way adopted here. They found considerable emergence of sodium from the sodium-rich muscles. This, however, was not appreciably inhibited by cyanide, and hence would seem to be different in kind from the results described here, in which even 2 mM cyanide completely inhibits excretion. The sodium emergence described by these workers may be largely of a passive kind, though it would appear to be much reduced by low temperature. The findings are considered in greater detail elsewhere[10].

Concentration of Thiocyanate labelled with Sulphur-35 in the Thyroid of the Hamster

THIOCYANATES are known to inhibit the concentration of iodide by the thyroid. We have found that labelled thiocyanate is concentrated in the follicles of the hamster's thyroid. Adult hamsters were given ^{35}S-thiocyanate (150 μc. with 100 μgm. of carrier) by intramuscular injection. The thyroid was removed 1 hr. later and dried from the frozen state at − 40° C. Contact autoradiographs were then made from sections of the dried tissue[1]. Patches of blackening were seen on the autoradiographs, corresponding to the areas of colloid in the section (Fig. 1). The density of the photographic grains over the centres of the follicles varied from 2·1 to 4·9 times the density over the centres of blood-vessels, the density over the smaller areas of colloid tending to be greater than that over the larger areas.

Thyroids were removed from other hamsters 1 hr. after injection of ^{35}S-thiocyanate and the radioactivity compared with that in the plasma and whole blood (unpublished work). The ratio of the concentration of sulphur-35 in the thyroid to that in the plasma averaged 0·57, and in the thyroid/blood it averaged 0·56. Portions of thyroid taken from the same hamsters were homogenized with water, and the whole homogenate chromatographed on paper with the solvents recommended by Pollard and McOmie[2]. The radioactivity on the chromatogram was found to be confined to two well-defined peaks, one at R_F 0·10 (the R_F value of sulphate ion in the solvents used) and the other at R_F 0·75 (the R_F value of thiocyanate ion) (Fig. 2). The first peak of radioactivity accounted for 5–15 per cent and the second peak for about 85 per cent of the total on the chromatogram. Chromatograms made from plasma taken at similar intervals after injection of ^{35}S-thiocyanate showed 95 per cent of their radioactivity at R_F 0·75.

We conclude that thiocyanate ions are concentrated in the follicles of the thyroid as the unbound ion, some of them undergoing chemical change in the thyroid, probably by oxidation to unbound sulphat The low value of the ratio of the concentration sulphur-35 in whole thyroid to that in the plasn may be explained by the small proportion of tl total mass of thyroid tissue in which selective co centration occurs, and by the presence of muscle ar connective tissue removed with the thyroid.

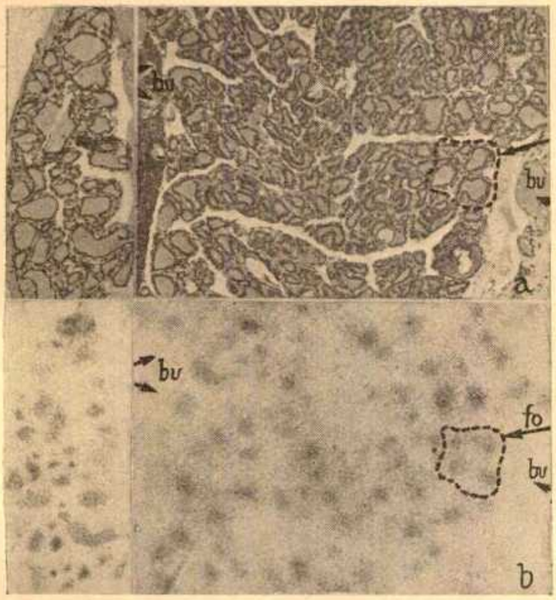

Fig. 1. Thyroid of hamster. (*a*) Sections stained with hæmotoxylin and eosin. (*b*) Autoradiographs from same sections. *fo*, Group of follicles; *bv*, blood-vessel. Corresponding areas shown on autoradiograph

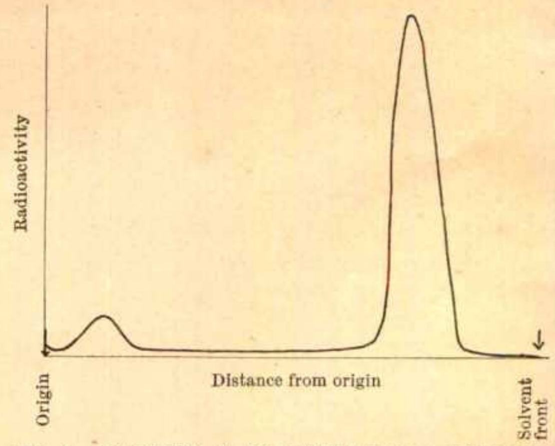

Fig. 2. Distribution of radioactivity along ascending paper chromatogram made from homogenate of thyroid 1 hr. after injection of ^{35}S-thiocyanate. Solvents: butanol, pyridine, water and ammonia

The pattern of blackening shown by ^{35}S-thi cyanate is similar to that shown by radioiodide wh thyroxine synthesis is blocked by propyl thiouraci This suggests that the inhibitory action of the thi cyanate ion on the concentration of iodide by tl thyroid is due to competition between the two io for the same transport mechanism.

Octadecadienoic Acids of Lamb Caul Fat

IN the course of investigations on the fat of rum contents[1], it was observed that the iodine valu of C_{18} unsaturated fatty acid fractions were su stantially higher than could be accounted for by tl content of diene and triene acids determined l alkali isomerization[2]. However, the amounts material isolated were small, and in order to invest gate further the acids responsible for this anomal the methyl esters of the C_{18} unsaturated acids fro the caul fat of lambs two to three weeks old, earli described[3], were used.

Crystallization of 52·5 gm. of the C_{18} concentra three times at −60° C. from ten volumes of aceto yielded 12·0 gm. (iodine value 145·3) of solub constituents. These were chromatographed[4] silica gel to yield concentrates of diene acids.

ble 1. COMPOSITION OF C_{18} DIENE CONCENTRATES FROM LAMB CAUL FAT

raction	Weight (gm.)	Iodine value (Wijs 1 hr.)	Diene (%)* (a)	Diene (%)* (b)	Triene (%) (a)	Triene (%) (b)
1	0·65	110·7	—	—	—	—
2	0·66	150·7	—	—	—	—
3	0·50	163·1	33·8	89·5	Nil	Nil
4	0·54	165·7	29·4	92·4	Nil	Nil
5	2·30	182·0	29·5	89·0	12·7	11·0
6	0·53	237·6	—	—	—	—

* In all cases conjugated diene acids amounted to less than 0·6 per nt.
(a) From isomerizations.
(b) Calculated from iodine values, assuming fractions 3 and 4 to ntain mono-ene and diene, and fraction 5, diene and triene acids nly.

It is apparent that the content of diene acids stimated by isomerizations is about one-third that lculated from the iodine values. This suggests the resence of considerable proportions of non-conjugable iene acids.

To obtain further information 0·21 gm. of fraction 5 as ozonized in 15 c.c. of chloroform at −10° C., nd the ozonides taken to dryness *in vacuo* at room mperature. After standing for two days with erhydrol, the aqueous solution was extracted with ght petroleum (boiling point 40–60°). The water-luble acids were taken to dryness and chromato-raphed on silica gel according to the procedure of Marvel and Rands[5]. The acids were identified by means of their peak effluent volumes as compared with those of a standard mixture. Expressed as a ercentage of the original ester ozonized, they were : malonic 1·6, succinic 8·2, glutaric 2·9, adipic 3·1.

The identity of succinic acid was confirmed by means of its melting point, along with that of its iphenacyl ester.

Since free dicarboxylic acids could only come from xidative cleavage of the double bonds, the presence f such acids of longer chain-length than malonic n the products of ozonolysis of fraction 5 suggests hat there are present in lamb caul fat isomers of noleic acid having double bonds separated by two r more methylene groups. Van der Veen[6] has shown hat isomers of linoleic acid are produced on catalytic ydrogenation of methyl linolenate, while Rebello nd Daubert[7] demonstrated that three of these iso-ners were the 8,14-, 9,15- and 10,14-octadecadienoic cids. Since Reiser[8] has shown that polyunsaturated cids are hydrogenated by rumen micro-organisms, he presence of isomers of linoleic acid in lamb caul at could be explained by assuming their formation n the rumen and deposition in the depot fat.

The isomers of linoleic acid present in the caul fat mount to 1·2 per cent of the total fatty acids.

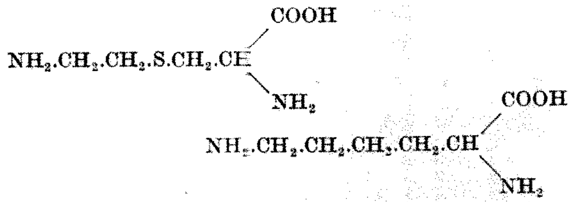
A New Synthetic Substrate for Trypsin and its Application to the Determination of the Amino-acid Sequence of Proteins

THE problem of the determination of the amino-acid sequence of a protein would be greatly simplified if methods were available for specifically hydrolysing peptide bonds involving a particular amino-acid. No satisfactory chemical method of doing this has been found, and the only controlled methods of hydrolysis available at present are digestion by proteolytic enzymes, in particular chymotrypsin and trypsin. It seemed possible that useful results might be obtained if a particular amino-acid side-chain could be modified in such a way as to resemble as closely as possible the side-chain involved in the specificity requirements of some enzyme. If the resemblance could be made sufficiently close, the enzyme might then hydrolyse the adjacent bond.

The hypothesis has been tested by studying the action of trypsin on the polymer of S-(β-aminoethyl-) cysteine. The side-chain of this amino-acid bears a strong resemblance to that of lysine, a —CH_2— group being replaced by a sulphur atom :



$NH_2.CH_2.CH_2.S.CH_2.CH(COOH)(NH_2)$

$NH_2.CH_2.CH_2.CH_2.CH_2.CH(COOH)(NH_2)$

S-(β-aminoethyl-) cysteine Lysine

A sulphur atom occupies much the same volume as a —CH_2-group, and the bond angle for sulphur is 100° compared with the 109·5° for a tetrahedral carbon atom. The preparation of the amino-acid polymer followed standard procedures and in outline was as follows. Cystine was reduced by sodium in liquid ammonia and coupled with N-carbobenzoxy β-bromo-ethylamine to give S-(β-carbobenzoxyaminoethyl-) cysteine. This was then converted to the dicarbo-benzoxy derivative and hence via the acid chloride to the N-carboxyanhydride of S-(β-carbobenzoxy-aminoethyl) cysteine, which was polymerized by heating at 110°. Removal of the protecting carbo-benzoxy group gave the hydrobromide of the polymer of S-(β-aminoethyl-) cysteine. This was soluble in water but could be precipitated from aqueous solution by the addition of ethanol. Fig. 1 shows chromato-graphic evidence that the polymer is an excellent substrate for trypsin.

It has also been shown that the thiol groups of reduced wool will react quantitatively with β-bromo-ethylamine in 0·5 *M* sodium carbonate at room temperature overnight. S-(β-aminoethyl-) cysteine resembles lysine so closely in its chromatographic behaviour that it is not possible to separate them on a two-dimensional chromatogram using butanol/acetic acid and phenol/ammonia. However, it was shown that the hydrolysate of wool treated in this way gave a spot which reacted with iodoplatinate and occurred in the position occupied by lysine, which suggests strongly that the cysteine residues of the reduced wool have been converted to S-aminoethyl cysteine residues by the treatment. Although direct evidence on a protein has not yet been obtained, it would seem likely that peptide bonds involving

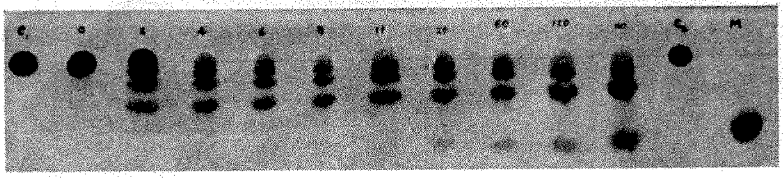


Fig. 1. Chromatogram showing hydrolysis of polymer of S-(β-aminoethyl-) cysteine by trypsin. Experimental conditions: 19·4 mgm. polymer hydrobromide/ml., 0·08 mgm. crystalline trypsin (Worthington)/ml., 0·1 M sodium bicarbonate (final pH 7·4), T = 26°. The numbers 0–120 refer to the time in minutes before spotting the sample on the paper, the reaction being stopped by the prior application of a spot of glacial acetic acid. The ∞ symbol refers to a solution from a similar experiment which had been left at laboratory temperature for twelve days. C_1 and C_2 refer to control solutions of the polymer in the absence of enzyme at times 0 and 120 min. respectively, while M is a sample of the monomer S-(β-aminoethyl-) cysteine. The chromatogram was run on Whatman No. 1 paper for five days using butanol/acetic acid/water/pyridine (30 : 6 : 24 : 20) as solvent (ref. 2)

cystine or cysteine residues in proteins will be specifically split by trypsin if they are converted to S-aminoethyl cysteine residues.

It is proposed to use this technique, first in an attempt to confirm earlier conclusions on the mode of reduction of insulin[1], and secondly in an endeavour to obtain information on the location of cystine residues in the wool proteins.

It might well be that the analogous O-β-aminoethyl derivative of serine would behave in a similar fashion if some simple method of converting the serine side-chains were available. It is not intended to investigate this possibility at present.

The Major Anthocyanin Pigments of the Wild Strawberry (*Fragaria vesca*)

ALTHOUGH it has been definitely established that cultivated strawberries contain pelargonidin-3-monoglucoside as the major anthocyanin[1,2] and cyanidin-3-monoglucoside as a minor component[3], there is still some question about the identity of the pigments of *Fragaria vesca*. As a result of qualitative tests, Robinson[4] suggested in 1934 that the anthocyanin of *F. vesca* is pelargonidin-3-monogalactoside. In a more recent paper, Robinson and Smith[2] described a chromatographic procedure for distinguishing pelargonidin-3-monoglucoside and the galactoside, but left the identity of the anthocyanins of wild strawberries as an open question.

Strawberries from *F. vesca*, grown at Geneva, N.Y., were harvested in 1955 and stored at −18° for four months. These plants originated from one clone from East Malling, England. The thawed berries were pressed, and 300 ml. juice which had been saturated with sodium chloride was extracted with n-butanol; the extract was concentrated and the crude pigments precipitated with ether, yielding 0·6 gm. of red powder with an anthocyanin content of 7·5 per cent. The pigments were separated chromatographically by a procedure similar to that of Li and Wagenknecht[5]. The crude mixture, 120 mgm. in 0·75 ml. of the first aqueous phase plus 1·5 gm. silicic acid, was separated on a silicic acid column. The column was p pared from a slurry of 18·5 g silicic acid, 10·5 ml. of the fi aqueous phase and excess orga phase. The first developing s vent was 250 ml. of the orga phase from n-butanol, acetic ac chloroform and water (4 : 1 : 2·7 v/v), followed by 250 ml. the organic phase of the abo solvents in the ratio 4 : 1 : 5 v/v). 10-ml. fractions we collected and the optical densi determined at 525 mμ. As Fig. shows, resolution into four co ponents was accomplished. T two major pigments account for 93 per cent of t light absorption of the crude pigment extract 525 mμ. Recovery of the pigments from the colun was quantitative.

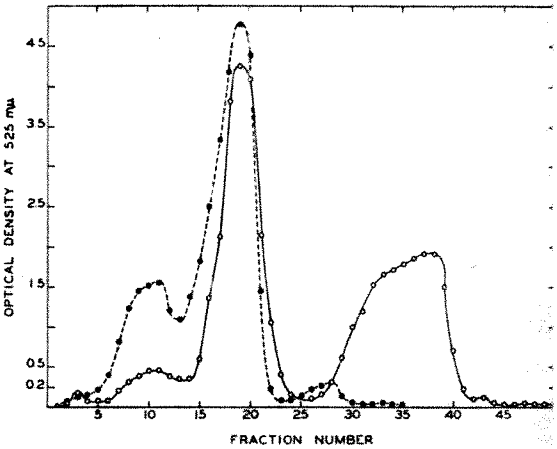

Fig. 1. Chromatographic separation of the anthocyanin pigments of wild and cultivated strawberries. ○——○, Pigments from *Fragaria vesca*, 120 mgm. crude pigments. ●——●, Pigments from cultivated strawberries, variety Culver, 40 mgm. crude pigments. In these solvent systems pelargonidin-3-monoglucoside, 1 mgm./10 ml., had an optical density of 4·38 and cyanidin-3-monoglucoside, 1 mgm./10 ml., had an optical density of 4·10 at 525 mμ

Fractions 14–26, band III, from two experimen were combined, the solvent evaporated and t residue converted to a crystalline picrate by trea ment with aqueous picric acid. Recrystallizatio from water and conversion to the chloride yielde 4·0 mgm. of chromatographically homogeneo material; R_F 0·40, on Whatman No. 1 paper an the solvent system n-butanol, acetic acid and wat (4 : 1 : 5)[6]. A mixture of this material and authent pelargonidin-3-monoglucoside yielded only one ban on the silicic acid column, and only one spot on pap chromatograms with the above solvent system. Th absorption spectra of band III and pelargonidin- monoglucoside in acidified ethanol also were identica Acid hydrolysis of the pigment from band III yielde a crystalline anthocyanidin which was shown to b indistinguishable from pelargonidin chloride by c chromatograming the aglycones (R_F 0·81 wit n-butanol saturated with 2 N hydrochloric acid), b comparison of their absorption spectra and by th usual colour tests. Chromatography with wate saturated phenol showed the sugar moiety to b indistinguishable from glucose, R_F 0·41, but readil separable from galactose, R_F 0·46. By analogou procedures the pigment from band IV (fractions 27 46) was shown to be indistinguishable from cyanidi nonoglucoside, R_F 0·32, and its drolysis products from cyanidin, $_F$ 0·68, and glucose.

On the basis of this evidence, it suggested that the major pig- ents of the fruit of *F. vesca* are largonidin-3-monoglucoside and anidin-3-monoglucoside. In the iits we examined, these pigments re present in a 1 : 1 ratio in wild rawberries, and 1 : 0·05 (pelar- nidin-3-monoglucoside to cyan- n-3-monoglucoside) in cultivated rawberries. Thus, the major dif- ence in the pigment composition wild and cultivated strawberries pears to be in the ratio of pelar- nidin to cyanidin glucosides.

Incidental to this study, evidence s obtained for the presence of other anthocyanin, band II, actions 7–12. This may be a cond pelargonidin derivative since has the same absorption spectrum pelargonidin-3-monoglucoside, but can be sep- ated from it on the silicic acid column. This material s absent in a pelargonidin-3-monoglucoside sample ich had been isolated from cultivated straw- rries and purified by recrystallization of its picrate[1]. e substance accounts for 6·5 and 21 per cent of e absorption at 525 mμ of the *n*-butanol extracts m wild and cultivated strawberries respectively. nd I, fraction 3, from the wild strawberries pears to be an anthocyanidin.

Crystal Structure of Biotin

BIOTIN (vitamin H) is a substance of considerable ological interest. It has been found to have the ructural formula[1] shown in Fig. 1; but chemical vestigations have not elucidated with certainty e configuration about the three asymmetric carbon oms.

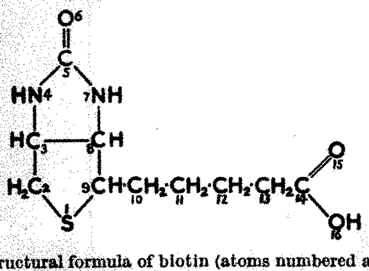

Fig. 1. Structural formula of biotin (atoms numbered arbitrarily)

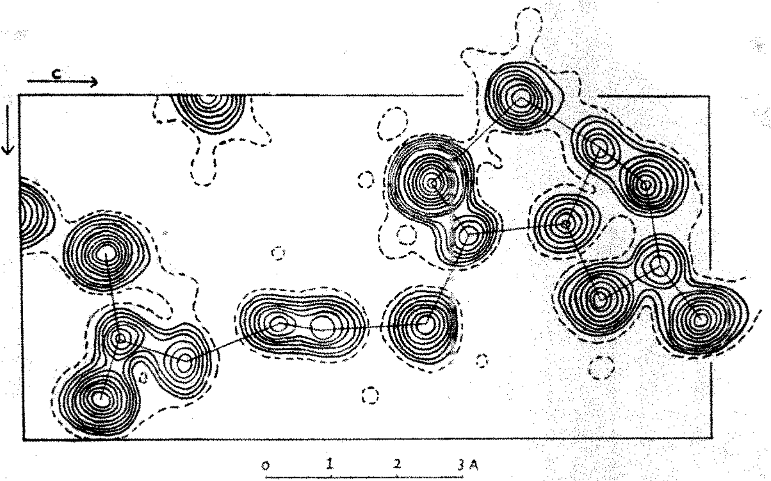

Fig. 2. Electron density projection on (100). Contours at intervals of one electron per A.^{2}, except for sulphur atom, where intervals are two electrons per A.^{2} after the seven-electron line. The two-electron line is broken

Crystals of biotin were found to be orthorhombic with unit-cell axes $a = 5{\cdot}19$ A., $b = 10{\cdot}33$ A., $c = 21{\cdot}00$ A., in good agreement with values previously reported by Fankuchen[2] and Crocombe (unpublished work). The density of the crystals, as found by flotation in a chloroform–benzene mixture, is 1·42 gm./cm.^{3}, necessitating the presence of four molecules of biotin in the unit cell. An examination of the X-ray spectra for systematic absences showed the space group to be $P2_12_12_1$.

Equi-inclination Weissenberg photographs were taken about the *a*- and *b*-axes up to the third and seventh reciprocal-lattice layers respectively. Some 70 per cent of the spectra falling within the sphere of reflexion for copper radiation were actually recorded, and a visual estimation made of their intensities.

As a first attempt at structure analysis, the Patterson projections along the *a*- and *b*-axes were calculated. However, in view of the large number of interatomic vectors arising from the 16 atoms (other than hydrogen) in the asymmetric unit, their interpretation proved very difficult, and it was not found possible to locate even the sulphur atom unequivocally. Seven sections of the three-dimensional Patterson function were then evaluated. These were at $u = 0, \frac{1}{4}, \frac{1}{2}$; $v = 0, \frac{1}{2}$; $w = 0, \frac{1}{2}$ (where u, v, w are expressed as fractions of the unit-cell axes a, b, c). The position of the sulphur atom was now easily found from an examination of the three Harker sections ($u = \frac{1}{2}$, $v = \frac{1}{2}$, $w = \frac{1}{2}$), and this was used to produce superposition maps from the Patterson projections by the method of Buerger[3]. Though even the *bc* Buerger map was not sufficiently well defined to enable the location of individual atomic positions, it gave a general outline of the shape of the molecule and proved a valuable guide during the subsequent analysis of the three-dimensional Patterson diagram. Because of the short *a*-axis and the fact that the Patterson diagram was not sharpened, all the sixty relatively heavy peaks corresponding to vectors between the sulphur and the other atoms in the molecule were in fact recorded on one of the sections $u = 0$, $\frac{1}{4}$ or $\frac{1}{2}$ (though several were very small and poorly resolved). A systematic correlation of these peaks (four for each atom) enabled a satisfactory trial structure to be obtained.

The *a*-axis projection was refined by a series of four Fourier syntheses in the course of which the reliability index, $R = (\Sigma \|F_0| - |F^c\| / \Sigma |F_0|$, decreased from 0·41 to 0·20. The final electron density projection is shown in Fig. 2. As a Fourier projection along the *b*-axis showed very poor resolution, the *x*-parameters alone were refined by the method of least squares. This was done in three stages, in the last of which all the observed *h0l* reflexions were used. The final value of *R* for this projection is 0·23.

The analysis confirms the accepted structural formula for biotin. The molecule has the *cis* configuration at the junction of the two five-membered rings, and though the configuration about bond C_8—C_9 is somewhat staggered, the aliphatic chain is *cis* with respect to the ureido ring system. These results are in accord with the suggestions of Grob and von Sprecher[4].

Within the limits of error, the six atoms of the ureido ring system are planar, as are the four carbon atoms of the adjacent ring; the two planes making an angle of approximately 120°. The sulphur atom lies 0·75 A. off the second plane, thus giving the ringed portion of the molecule a boat-shaped configuration. Whereas the four carbon atoms in the aliphatic chain follow approximately the normal planar zigzag configuration, the bond C_9—C_{10}, which links the chain to the ring system, does not conform to this pattern and consequently the molecule is considerably elongated. Hydrogen bonds O_6—O_{16}, O_{15}—N_4 and O_{15}—N_7 serve to bind all the molecules in the crystal together.

A further refinement of the structure using the full three-dimensional data is now in progress, and when this is completed a more detailed account of this work will be published elsewhere.

Surface Tension as the Cause of Bénard Cells and Surface Deformation in a Liquid Film

IN 1900, Bénard[1] described his observations of a cellular deformation produced on the free surface of a liquid film the bottom surface of which (in contact with a floor) was uniformly heated and hotter than its top surface. He also observed a cellular flow associated with the deformation. These studies were made on films of thicknesses in the range 0·5–1·0 mm.

Rayleigh[2] and others analysed this phenomenon as an instability due to the density increasing from bottom to top. They obtained a critical film thickness below which there is stability.

This explanation in terms of density variation may be sufficient in the case of films thicker than about 1 mm. or when the liquid film has no free surface. Indeed, experimental investigations by Schmidt and Milverton[3] reveal a cellular motion in a liquid film bounded by horizontal plates, when the bottom plate is hotter than the top plate, that in agreement with the analyses. However, Béna cells, specifically defined here as the hexagonal ce in films (thinner than about 1 mm.) with a free su face, may not be due to convective instability.

We have carried out the following experimer with a number of liquids. Bénard cells were esta lished, for example, in a hydrocarbon liquid. needle point was wetted with a silicone insoluble the hydrocarbon. The needle point was then ma to touch the surface of the hydrocarbon film e hibiting Bénard cells. A skin or layer was there floated off and the effects observed as it spread ov the surface. Wherever and as soon as the layer pass over the Bénard cell, the surface deformation d appeared and the flow stopped. Clearly the variati of vertical density could not be affected so rapid by the covering by the layer.

Consider now that both the Bénard cell moti and deformation are produced by variations in t surface tension; which are in turn due to variatio in temperature. We may then apply the work Hershey[4], who analysed the flow and the deformati produced by a uniform surface stress arising fro a surface tension gradient (due to a temperatu gradient). Hershey also observed that the deform tion caused by a local cooling disappeared when insoluble monolayer covered it, explaining that t monolayer "takes up the tangential stress". Hershey analysis can be extended, for example, to accou for Bénard's observation that the colder parts the surface are the higher parts. On the other han Jeffreys[5] predicted, on the basis of free convectic that the hotter part should instead be the higher pa

I have therefore carried out the following expe ments. Bénard cells were first produced and th removed by covering with a monolayer. Then t thickness of the liquid film (covered by a monofil was increased until cellular surface deformation a circulation could again be seen. The thickness which this occurred was 2 mm., which is, in tl case, about the predicted critical depth for the ons of convective instability. The cellular deformati that occurred at 2 mm. did not have as regular pattern as the hexagonal Bénard cells previous obtained with a clean liquid surface. This irregul pattern occurred both when the surface was cle and when it was covered with the monofilm. Howeve decreasing the temperature at the base of a fil showing an irregular pattern caused the producti of the typical hexagonal Bénard pattern.

Bénard cells were observed, during these expe ments, for a thickness as small as 50 microns. that thickness, there was no indication that t limiting thickness, below which there would stability, had been reached. This thickness is least an order of magnitude smaller than the predict critical depth for convective instability.

Finally, I carried out an experiment in which liquid film (about 0·8 mm. thick) with a free surfa was cooled at its base and should therefore ha been convectively stable. Nevertheless, cellul patterns were observed, the more regular patter having the appearance of Bénard cells. It wou therefore appear that the instability causing Béna cells is quite different from the Rayleigh instabilit

Convection has also been considered, erroneousl in another case. Heintz[6] made an experiment study of the surface deformation caused by a te perature variation in liquid films (0·3–1·0 m thick). In a qualitative way he ascribed the effe convection. I have obtained similar experimental futation as in the case of the Bénard cells, again ing a floating layer. The importance of considering e role of surface tension in this phenomenon is ustrated by the failure of Heintz to obtain the fect he describes in water. However, whenever fficient care was used so as not to contaminate the ater surface, we obtained the effect.

A New Uncertainty Relation

ONE of the consequences of the introduction of a ometry of four dimensions as a basis of physical ieory has been to reveal relations between certain uantities which had previously appeared to differ indamentally in character, the simplest being the elation between space and time. In geometries which itroduce new parameters or new dimensions, a milar unexpected unification may appear. This is articularly the case in the theory based upon the se of projective geometry associated with the names f Veblen and Hoffmann, and with the five-dimenonal theory introduced by Kaluza. It is necessary o express any results obtained in this way in a form hich satisfies the requirements of relativistic inariance; but the development of both these heories has proceeded in such a way as to make this ossible.

In this framework the principles of conservation of nergy and momentum are seen to be parts of a ider principle which embraces that of electric harge also. It was suggested also that an additional ondition should be added to the relations $\int p\,dq = nh$ f the old quantum theory, and this was interpreted s expressing the quantization of electric charge[1]. In he light of a recent discussion[2] concerning the fourimensional interpretation of such results, a new ncertainty relation is suggested. To the four familiar onditions it seems natural to add $\Delta m_0 \Delta\tau \sim \hbar/c^2$. he interpretation would be that in order to measure rest-mass m_0 to the accuracy Δm_0, an interval of roper time $\Delta\tau$ must elapse, the two quantities Δm_0 nd $\Delta\tau$ satisfying the above inequality.

This condition is also suggested by a work by K. H. zou[3] on the relativistic form of Heisenberg's quanum equation, in which the quantities m_0c and $c\tau$ ccur in such a way as to suggest a pair of conjugate uantities.

An application of it would be to cases of the ransformation of nuclear particles in which the time f decay, being the time available for observation, ould limit the observable change of rest mass.

At first sight the relation appears to be a special ase of the energy relation:

$$\Delta E\,\Delta t \sim \hbar$$

which for a particle of mass m in the absence of a field of force becomes,

$$\Delta m\,\Delta t \sim \hbar/c^2$$

This is usually applied to cases where the rest mass does not change. If it be assumed that it applies to the case of a particle which changes its rest mass while at rest, Δm is a change of rest mass and Δt a change of proper time.

The two conditions are the same in this case. Prof. P. Caldirola[4] has applied the energy relation in this way. Adopting the view that a μ-meson is an electron in a higher energy state, he points out that

$$(\mu_0 - m_0)\,\Delta t \sim \hbar/c^2$$

μ_0 and m_0 being the respective rest masses, and discusses the significance of the relation on the assumption that a minimum interval of time Δt exists. But the relation proposed here is not essentially an energy relation, and its application is not restricted to cases where the particle under consideration is at rest. When no restriction is placed upon the motion of the particle, the two conditions do not coincide. It is suggested that the rest mass condition is an independent one.

Fixation of Carbon Dioxide into the Carboxyl Carbon of Glycine

IT has been observed that carbon dioxide is a precursor to the carboxyl carbon of glycine in incubations with a hen-oviduct mince. Carbon 2 of the glycine is completely unlabelled when determined as the formaldehyde dimedone complex obtained after ninhydrin degradation. Carboxyl-labelled acetate is also formed in this system from carbon dioxide[1]. Acetate 1,2-^{14}C, however, was found to be a poor precursor to glycine, although it was converted to glutamic acid much more efficiently than carbon dioxide.

These observations appear to diminish the likelihood that carbon dioxide is entering glycine through acetyl coenzyme A or acetate directly. There appear two possible explanations. Glycine may be formed directly from an activated acetyl compound arising from the carbon dioxide fixation previous to acetyl coenzyme A, or carbon dioxide may be fixed independently to two distinct acceptors, one of which yields acetate and the other glycine.

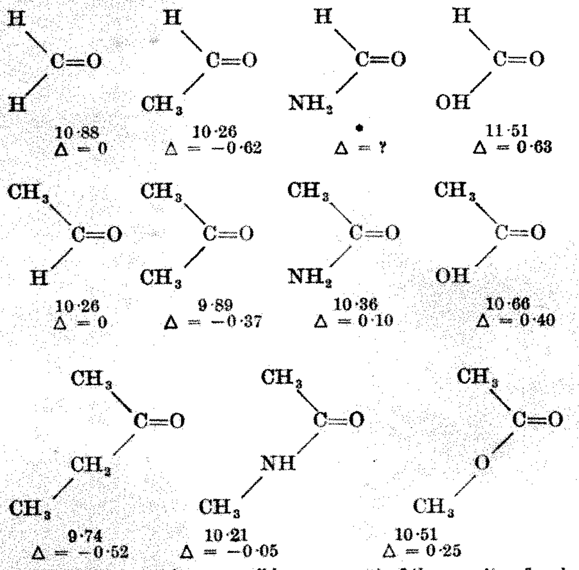
Ionization Potentials of Carbonyl Molecules

THE first ionization energies of carbonyl molecules are largely determined by the non-bonding electrons at the oxygen atom of the carbonyl group. If electric charge flows from the other part of the molecule into the oxygen, the effective electro-negativity of that atom will become decreased, and hence the ionization potential of the molecule will be reduced[1]. From this point of view, it is expected that the magnitude of the ionization potential will serve as a clue to the state of electron transmission in a carbonyl molecule.

In the present work, measurements were made of the first ionization potentials by use of a Hagstrum type mass-spectrometer[2]. The evaluation of the potentials was made according to the critical slope method[3], argon being employed as the calibration gas. The results are recorded in Table 1.

Table 1. FIRST IONIZATION POTENTIALS (eV.)



* No measurement was possible on account of the scarcity of molecular ion formed.

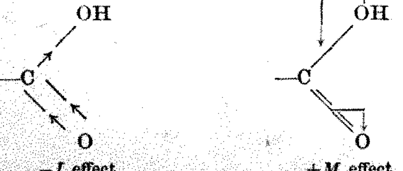
It will be seen that the replacement of a hydrogen atom in H·CHO and H·COCH$_3$ by CH$_3$ or CH$_2$·CH$_3$ lowers the potential values, while replacement by NH$_2$, OH or OCH$_3$ tends to raise them. This trend in the potentials may be accounted for if the inductive mechanism is taken into consideration. That is, the Ingold's sequence[4] of $-I$ effect is:

(a) $OH > NH_2 > H$; $OCH_3 > NHCH_3 > H$

and that of the $+I$ effect is

(b) $CH_2(CH_3) > CH_3 > H$

This is rather surprising, since the mesomeric effect of the group (a) which counteracts the $-I$ effect is supposed to be more important. Both effects are illustrated for the group —CO·OH.



$-I$ effect $+M$ effect

Effects of Pressure on the Superconductin Transition in Tin

RECENTLY, Muench[1] has investigated the displac ment of the critical temperatures T_c of tin and indiu produced by pressures of up to 100 atmospher (obtained by compressing helium gas), and by pressure of 1,900 atmospheres (obtained by the ic expansion bomb technique); and he has measure the value of $(\Delta H_c/\Delta p)_T$, where H_c denotes the critic magnetic field and p the pressure, at temperatur between 1° K. and T_c for each of these metals. The experiments are important in that they provide t most complete data yet obtained on the effects pressure on the superconducting transition.

In analysing his results, however, Muench assume that $(\partial H_c/\partial p)_T$ is independent of pressure. There no satisfactory experimental evidence in support this hypothesis: the earlier work of Kan, Sudovsto and Lasarew[2] at pressures of 1,350 and 1,700 atm spheres was not sufficiently accurate to allow on to deduce that $\partial^2 Hc/\partial p^2$ is negligibly small, whi Muench's own work only suffices to show that, at given temperature, H_c is a linear function of pressu within experimental error over the very restricte range between 0 and 100 atmospheres. Indeed, review of experimental results concerning secon order partial derivatives shows that the evidence i favour of $(\partial H_c/\partial p)_T$ being substantially independe of pressure is much less convincing than is that i favour of $(\partial T_c/\partial p)_H$ being substantially independe of pressure. Chester and Jones[3], for example, hav succeeded in extending almost tenfold the pressur range over which the superconducting transition i tin has been observed without thereby being ab to detect lack of linearity in the relationship betwe T_c and p; and, although their accuracy was not a high order at a pressure of 17,500 atmospheres, it significant that, within experimental error, the results conform to the same straight line as do the le extensive measurements of Kan, Sudovstov an Lasarew.

By making use of a consistency relation betwe the first- and second-order partial derivatives whic holds at any typical point on the H_c—T—p surfa separating the superconducting and the norm phases, it is possible to devise an iterative comput tional procedure whereby the Muench assumption pressure-independence of $(\partial H_c/\partial p)_T$ can be dispense with, and values for $\partial^2 H_c/\partial p^2$ can be deduced fro his data. Preliminary calculations made on this bas for the case of tin show that $\partial^2 H_c/\partial p^2 = -8 \times 10^{-}$ gauss dyne^{-2} cm.[4] at the zero-pressure critical ten perature of 3·73° K. The value of $\partial^2 H_c/\partial p^2$ increase as the temperature is reduced, becomes zero at abou

4° K., and remains positive between this latter mperature and 1° K. The work so far completed ggests that $\partial^2 H_c/\partial p^2$ may become as large as $\times 10^{-19}$ gauss dyne^{-2} cm.[4] at the lower end of the mperature-range covered by Muench's experiments. From the zero-pressure values computed for $H_c/\partial p)_T$ it is possible to deduce that, for any fixed mperature in the neighbourhood of T_c, it would be cessary to apply a pressure of at least 2,000 atmoheres to tin in order to produce an overall departure om linearity of 1 per cent in the relationship between $_c$ and p. It would, of course, not be easy to check perimentally such a small deviation from linearity, cause of the difficulty of measuring pressures of is order of magnitude with adequate precision.

A fuller account of the work will be presented in ie course.

Interior Deformation Markings in Copper Fatigue Specimens

A METALLOGRAPHIC investigation of several fracred low-stress rotating cantilever specimens of lowygen copper was carried out, employing various chants, in an attempt to detect metallographically y evidence of deformation in the interior. Average mposition of the specimens was 0·0027 per cent ygen, 0·0007 per cent nitrogen, 0·8 c.c./100 gm. drogen, 99·95 per cent copper.

Wadsworth and Thompson[1] have electropolished pper fatigue specimens at various stages during e fatigue life, and have shown that, although most p bands are removed by polishing off 2μ, some slip nds persist, and that it is from these "persistent p bands" that fatigue cracks ultimately develop. heir observations have been restricted to the surface specimens.

In the present experiments, the specimens were pper plated, sectioned diametrically by a slitting heel flooded with coolant, polished mechanically d finally electrolytically polished in orthophosioric acid. The sections were then etched in each ten etchants in turn, an intermediate light polish ing given to remove completely the previous etch.

The etchants employed were those listed by muels[2] as capable of developing deformation markgs in copper and copper-base alloys. Briefly, they e:

1)	Potassium dichromate	5 gm.
	Sulphuric acid (conc.)	8 ml.
	Water	50 ml.
	Hydrochloric acid (conc.)	2 ml./50 ml.
2)	Ammonium hydroxide	1 vol.
	Hydrogen peroxide (3 per cent)	2 vol.
	Water	2 vol.
3)	Ferric chloride	5 gm.
	Hydrochloric acid (conc.)	10 ml.
	Water	100 ml.

4) 10 per cent phosphoric acid at 90° C.
5) 10 per cent ammonium persulphate at 50–60° C.
6) 10 per cent cupric chloride plus ammonia to alkalinity.
7) Electrodes of standard electropolishing bath short-circuited at end of polishing cycle.
8) Washed and dried specimen immersed in standard orthophosphoric acid polishing bath at 0·6–0·8 V.
9) 0·25 per cent sodium thiosulphate solution at 3·5 amp./dm.^{2}.
) 0·5 per cent sodium thiosulphate solution at 1 amp./dm.^{2}.

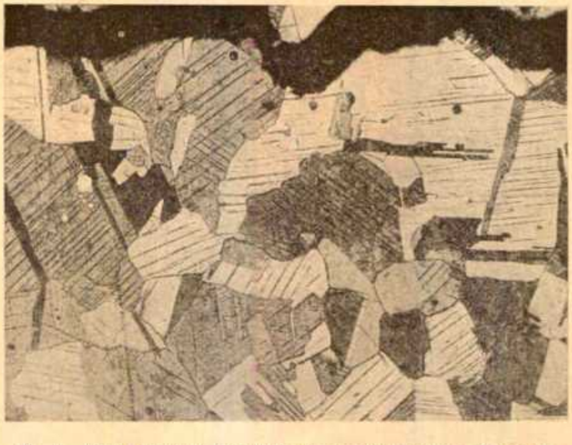

Fig. 1. Microstructure of rotating-cantilever specimen of copper, taken at the main fracture (black band) and on a section approximately 1 mm. under the original surface. Specimen fractured at 14,000 lb./sq. in. after 632,400 cycles at 21 c./min. Specimen axis vertical. Etched with acid ferric chloride. × 100

The results of using each of these etchants in turn showed that: (*a*) etchants (1), (4), (7), (9) and (10) produced a normal etch by developing grain boundaries, twin boundaries and oriented lustre in varying degrees; (*b*) etchants (2), (3), (5) (6) and (8) produced a similar etch, but in all cases the grains showed striations.

An area was selected on a specimen exhibiting these striations, and photographs were taken of this area after etching with each of the etchants in group (*b*) above. The striations observed were the same with each of these etchants, and simply varied in intensity. It was possible to arrange these etchants in order of decreasing effectiveness in developing striations, as follows: acid ferric chloride, cupric ammonium chloride, ammonium persulphate, electrolytic polishing cell etch, ammonium hydroxide – hydrogen peroxide.

An example of the striations is shown in Fig. 1. The area illustrated includes the main crack (black irregular band), and is approximately 1 mm. under the original curved surface of the specimen. This specimen had fractured at 14,000 lb./sq. in. after 632,400 c./min. Striations were observed in the area up to 5 mm. on either side of the main crack.

It will be noted that the striations bear no relation to the specimen axis, but are definitely crystallographic in nature, because: (i) they change direction when crossing an annealing twin; (ii) one or more parallel sets may be present in one crystal; (iii) they are essentially straight.

Samuels[2] has classified the deformation marks produced by compression in copper and copper-base alloys into four types, based on differences in visual appearance and on the orientation of the marks relative to the axis of compression. The striations shown in Fig. 1 do not correspond to any of these four types, and thus presumably indicate that deformation has occurred in the fatigue specimens in a different mode from that in compression.

The acid ferric chloride etch was used on specimens of the same copper, initially annealed and then deformed in tension to 1, 2, 4, 8, 10, 20, 30 and 40 per cent elongation, and also on a specimen cut from the compression side of a bent bar. Again in no case did the striations shown in Fig. 1 correspond to the deformation marks in the tension and compression specimens, a further indication that deformation has

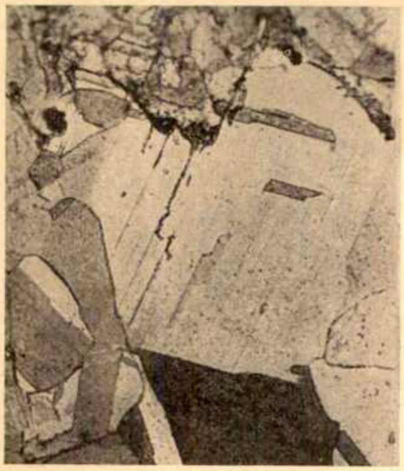

Fig. 2. Cross-section of the surface of a machined rotating-cantilever specimen of copper, showing short fatigue cracks running along striations. Specimen had fractured completely some 3 mm. from this point at 16,000 lb./sq. in. after 476,000 cycles at 170 c./min. Specimen axis horizontal. Etched with acid ferric chloride. × 370

occurred in the fatigue specimens in a different mode from that in tension and compression.

The striations are not produced by the sectioning technique, since they may also be readily developed on the polished surface of a similar fatigue specimen, free of striations before the fatigue test. Neither are the striations produced by gradual application of the stress during loading, since they do not develop until a later stage in the fatigue life.

Fig. 2 shows small cracks in a surface crystal of a low-stress rotating-cantilever specimen. The cracks run along the striations revealed by etching, indicating that these, or the mode of deformation which results in their development, may play an important part in the formation of fatigue cracks. Similar striations have also been observed in fractured low-stress push–pull specimens of copper. Thus, they appear to be characteristic of low-stress fatigue-deformation in copper. Experiments concerning the variations in intensity of the striations due to stress and to testing frequency are to be described shortly. Also, the nature of the markings is being investigated by annealing experiments and by electron microscope investigations.

This work forms part of the research programme on fatigue at the Aeronautical Research Laboratories, Department of Supply, Melbourne. Acknowledgment is made to the Chief Scientist, Department of Supply, for permission to publish this communication.

Mechanism of the Electrolytic Deposition of Titanium

ONE of the commercial methods of manufacturing pure titanium metal involves the high-temperature electrolysis of either K_2TiF_6, $TiCl_4$ or $TiCl_3$ in a molten alkali halide eutectic. Several such processes have been in operation for some time, and certain details of the preparative techniques have been published[1]. The mechanism of these electrolytic methods has, however, remained in doubt. Of the two possibilities, (1) primary deposition of a titanium ion, complex or otherwise, on to a suitable cathode or (2) secondary deposition where the titanium species are reduced by electrolytically produced alkali metal, the latter has seemed more probable because of the amorphous nature of the resultant titanium. It is true that fairly large dendritic crystals of titanium are produced during the electrolysis, but such dendrites are also found in the commercial preparation of titanium where $TiCl_4$ is reduced with liquid sodium. The current–voltage relations observed during electrolysis are also in keeping with a predominantly secondary process.

Recently, we have obtained direct evidence that the metal is finally produced by a secondary process but, depending on the starting materials, this can be preceded by one or more primary steps. Using the gas-flushed tungsten micro-electrode, recently developed by Inman[2], polarographic analyses have been made of solutions of K_2TiF_6, $TiCl_4$, $TiCl_3$ and $TiCl_2$ in the LiCl—KCl eutectic at temperatures between 380° and 550° C. Excellent reversible polarograms have been obtained for the primary reduction of $TiCl_3$ to $TiCl_2$, the half-wave potential with respect to platinum being $-2 \cdot 58$ V. at 400° C., that for the decomposition of the eutectic being $-2 \cdot 79$ V. The wave-height is strictly proportional to the concentration of $TiCl_3$ up to 0·01 weight per cent corresponding to ~ 200 μamp., the highest current measurable with the recorder. The log $i/i_d - i$ against E relation indicates a one-electron reduction step. That the reduction is to $TiCl_2$ and not to titanium metal is also evident when, after complete reduction, the reverse process is clearly indicated from the corresponding anodic polarogram.

$TiCl_4$ gives a cathodic wave at $E_{1/2} = -1 \cdot 4$ V. at 400° C., although its form is distorted because of the difficulty in maintaining any concentration of $TiCl_4$ in the melt.

Neither $TiCl_2$ nor K_2TiF_6 gives a detectable cathodic wave or limiting current. A finite current only flows when the applied voltage exceeds $-2 \cdot 79$ at 400° C. that is, the decomposition potential of the pure eutectic. It is therefore clear that K_2TiF_6 and $TiCl_2$ in this melt at least, can only be secondarily reduced to titanium by chemical reaction with alkali metal.

FORTHCOMING EVENTS

Tuesday, September 25

Institution of Civil Engineers (at Great George Street, Westinster, London, S.W.1), at 5.30 p.m.—Mr. F. R. Farmer: "The roblem of Liquid and Gaseous Effluent Disposal at Windscale".

Society of Instrument Technology (at Manson House, Portland lace, London, W.1), at 6 p.m.—Presentation of Bowen Prize by r. G A. Whipple. Dr. E. A. Spencer and Mr. A. T. J. Hayward: The Accurate Calibration of Flowmeters".

Wednesday, September 26

British Institution of Radio Engineers (at the London School f Hygiene and Tropical Medicine, Keppel Street, Gower Street ondon, W C.1), at 6.30 p.m.—Dr. H. W. Loeb: "Some Aspect f Transistor Progress".

Friday, September 28

Association of Applied Biologists (in the Mining Lecture heatre, Royal School of Mines, Prince Consort Road, London, S.W 7), t 10.30 a.m.—Symposium on "The Use of Antibiotics Against Plant, iseases".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or efore the dates mentioned:

Lecturer or Assistant, Grade B (with special qualifications in lant physiology and preferably teaching and research experience) Botany—The Clerk to the Governors, Chelsea Polytechnic, Manresa oad, London, S.W.3 (September 28).

Biochemist, Senior Grade (with a first- or second-class honours egree), for duties which include both routine hospital biochemistry nd work connected with the investigations into the uses of radioctive isotopes in medicine—The Secretary, Liverpool Radium nstitute Management Committee, 1 Myrtle Street, Liverpool 7 September 29).

Chemist (with a first- or good second-class honours degree or quivalent qualification and at least three years experience, and referably a knowledge of liquid fuels and lubricants) in the Central aboratory, Chiswick—The Recruitment and Training Officer (F/EV. 97), London Transport, 55 Broadway, London, S.W.1 (September 29)

Demonstrator (with a first- or second-class degree in chemistry) in the Department of Organic Chemistry—The Registrar, The niversity, Liverpool (September 29).

Entomologists (with at least a second-class honours degree in ntomology, and preferably a knowledge of botany and plant ecology echniques) in the Department of Tsetse and Trypanosomiasis ontrol and Reclamation, Federal Ministry of Agriculture, Federaion of Rhodesia and Nyasaland, for duties which will include field tudies and surveys in tsetse fly areas as a preliminary to land eclamation—The Public Service Attaché, Rhodesia House, 429 Strand, ondon, W.C.2 (September 29).

Physics Graduate in the Department of Radiotherapy, for vork which will include developments connected with rotation therapy, nulticurie cobalt units and the use of radioactive isotopes—The ssistant Administrator, Churchill Hospital, Oxford (September 29).

Scientific Officer (honours graduate) in the Plant Pathology ection to work mainly on seed-borne diseases—The Secretary, ational Vegetable Research Station, Wellesbourne, Warwick September 29).

Assistant Lecturer or Lecturer (with special qualifications n palæontology) in Geology—The Registrar, King's College, Strand, ondon, W.C.2 (October 1).

Lecturer (preferably with either (*a*) knowledge and experience f servo mechanisms or process control; or (*b*) research experience some branch of electronics) in Applied Electricity—The Secreary and Registrar, University College of North Wales, Bangor October 1).

Assistant (preferably with a special interest in vertebrates) in oology—The Secretary of University Court, The University, Glasgow October 5).

Lecturer in the Department of Metallurgy—The Registrar, he University, Liverpool (October 6).

Research Assistant (with a first- or second-class honours degree n chemistry) in the Chemistry Department—The Principal, Derby nd District College of Technology, Normanton Road, Derby (October)

Assistant Lecturer (Grade III) or Demonstrator in Pharmcology—The Registrar, The University, Bristol (October 8).

Staff Tutor in the Department of Adult Education—The egistrar, University College, Leicester (October 13).

Veterinary Bacteriologist (with a university degree in science r veterinary science, with honours, together with postgraduate research xperience in bacteriology, or equivalent qualifications) in the ivision of Animal Health and Production, Commonwealth cientific and Industrial Research Organization, Sydney, to participate n a research programme on the bacteriology of footrot and foot bscess, including studies on the pathogenesis and immunology of hese diseases; investigations on mycotic dermatitis and fleece rot f sheep will also be undertaken—Chief Scientific Liaison Officer, ustralian Scientific Liaison Office, Africa House, Kingsway, London, V.C.2, quoting Appointment No. 202/115 (October 13)

Lecturer in Inorganic Chemistry at the University College of hodesia and Nyasaland—The Secretary, Inter-University Council or Higher Education Overseas, 29 Woburn Square, London, W.C.1 October 15).

Lecturer (with a good honours degree, including heavy current subjects) in Electrical Engineering—The Secretary and Registrar, The University, Southampton (October 15).

Lecturer (Chemist) in the Department of Municipal Engineering—The Registrar, College of Science and Technology, Manchester 1 (October 20).

Director of the Computing Unit—The Secretary of Faculties, University Registry, Oxford (October 30).

Lecturer or Senior Lecturer in Fluid Dynamics at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Professor (with high academic qualifications and considerable experience in research or development work in metallurgy or generally in the science of materials) of Materials and Metallurgy—The Principal, College of Aeronautics, Cranfield, Bletchley, Bucks (October 31).

Reader in Marine Biology in the Department of Biology, University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 31).

Senior Lecturer in Mineral Engineering at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Director of the Medical Physics Unit—The Secretary to the University, Old College, South Bridge, Edinburgh (November 1).

Agronomist (preferably with a good honours degree and practical experience) at Gambia Rice Farm (H.M. Oversea Civil Service), to undertake experiments in the cultivation of irrigated rice and of alternative crops suitable for dry-season cultivation under irrigation—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/12/08.

Assistant Conservator of Forests (with a university degree in forestry or a degree in natural science supplemented by at least one years training in forestry) in Tanganyika (H.M. Oversea Civil Service)—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/8/01.

Assistant (Grade B) in the Department of Physics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W 3.

Assistant Lecturer in Agricultural Zoology—The Registrar, The University, Nottingham.

Bacteriologist, Scientific Officer or Senior Scientific Officer grade, to assist in work on the nutritional significance of micro-organisms of the digestive tract—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Bleachers' Association Limited Fellow in the Department of Textile Industries, for research on cellulosic fibres—The Registrar, The University, Leeds 2.

Graduate in Biological Science, to assist in research on mass culture of marine algae—The Professor of Zoology, The University, Southampton.

Laboratory Technician (with experience and skill in general bacteriological methods, and preferably special experience in methods applicable to studies on viruses and tissue culture work)—The Secretary, The Research Institute (Animal Virus Diseases), Pirbright, Surrey.

Lecturer or Assistant Lecturer (Grade B) in the Department of Mathematics—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Lecturers (with an honours degree) in Electrical Engineering, Physics and Mathematics—The Principal, Paisley Technical College, 28–40 George Street, Paisley

Leverhulme Senior Research Fellow (preferably with experience of bio-assay or radioisotope techniques), to work on the effects of steroid hormones in ruminants, and in particular, to investigate the physiological bases for the improvement of growth-rate resulting from hormone treatment—The Registrar, The University, Nottingham.

Physics Technician (preferably with a knowledge of vacuum technique)—The Director, Radiobiological Research Unit, Medical Research Council, Atomic Energy Research Establishment, Harwell, Berks.

Records Officer (with a university degree in natural science or agriculture or a related biological science, and preferably experience in publishing, collecting or abstracting scientific work) in the Department of Agriculture, Federation of Nigeria, to assist in the collection and dissemination of information on agricultural research within the Federation of Nigeria, and to assist in the preparation of scientific publications and memoranda—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/14/041.

Research Officer (Cyto-Geneticist) (with a good honours degree and at least two years postgraduate experience in plant genetics, and preferably training and experience in cytology) with the East African Agriculture and Forestry Research Organization, Kenya, to undertake genetical studies of crop plants aimed at providing basic knowledge for the breeding of plants for disease resistance and other qualities—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/151/01.

Research Worker (physics graduate), for investigations on physical properties of rubber-like materials—The Secretary, Research Association of British Rubber Manufacturers, Shawbury, Shrewsbury.

Science Graduate (metallurgy, chemistry) for administrative and technical duties—The Assay Master, Assay Office, Newhall Street, Birmingham 3.

Senior Laboratory Technician—The Secretary, Research Station, Long Ashton, Bristol.

Senior Lecturer (with a good honours degree and industrial or research experience) in the Strength of Materials—The Secretary, The Royal Technical College, Glasgow.

Senior Scientific Officer (with a first- or second-class honours degree in electrical engineering or physics, and three years postgraduate experience, and preferably some experience in any of the following. (*a*) millimicrosecond pulse techniques, (*b*) weapon firing trials, or (*c*) the development of weapon test instruments) to lead a team responsible for the development trials of electrical and electronic equipment for use in weapons—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. A.1059/94.

STATISTICIAN (with at least a second-class honours degree and not less than two years postgraduate experience in the application of modern statistical procedures to biological experimentation) with the East African Agriculture and Forestry Research Organization, to take charge of the Statistical Section of the Organization, to study and to advise on the design of biological experiments, to advise on the procedures for the statistical analysis of results, and to collaborate in experiments to study sampling techniques, etc.—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. BCD.195/151/05.

TECHNICIAN IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

New Books

Thermodynamic Functions of Gases

Edited by F. DIN, Ph.D., The British Oxygen Company Ltd. Price 63*s.* per volume.

This series of independent volumes deals with a number of industrially important gases. Vol. I covers Carbon Dioxide, Carbon Monoxide, and Ammonia. Vol. II covers Air, Propane, Acetylene, Ethylene and Argon.

Publication has been carried out under the auspices of the Department of Scientific and Industrial Research, H.M. Government, and the series forms the official publications of the surveys conducted by the Thermodynamics Committee of the Mechanical Engineering Research Board of D.S.I.R.

The temperature-entropy diagrams published in these volumes are also available, from the publishers, as enlarged wall-charts.

Gas Chromatography

By C. G. C. PHILLIPS, M.A., Demonstrator in Inorganic Chemistry, Oxford Price 25*s.*

This book is designed to give a broad survey of the work in the field but is especially designed with the object of assisting those who are using, or intend to use, gas chromatographic techniques themselves.

Valency and Molecular Structure

By E. CARTMELL, B.Sc., and G. W. A. FOWLES, B.Sc., Ph.D., Southampton. Price 32*s.* 6*d.*

This book is written by chemists for chemists, and will fill the need for an introductory text in which an elementary account of the development of the quantum theory is combined with a survey of its application to structural chemistry. It is mainly intended for first-year honours students, although Part III, which discusses recent work on the nature of the bonds in many molecules, is more suitable for advanced courses.

OFFICIAL APPOINTMENTS

NATIONAL COLLEGE OF FOOD TECHNOLOGY

CRANWOOD STREET, CITY ROAD, LONDON, E.C 1

Principal · J. D. Mounfield, M.Sc.Tech, Ph.D, F.R.I.C.

Applications are invited for the post of Lecturer in the College from science graduates, preferably in Microbiology, who have had experience in dairy technology. Facilities for research work are available. Teaching experience desirable but not essential. Salary scale (awaiting approval): £1,260 by £30 to £1,460. Starting salary dependent on qualifications and experience.

Application forms (obtainable from the Registrar), to be returned to Principal as soon as possible

LIVERPOOL RADIUM INSTITUTE MANAGEMENT COMMITTEE

1 MYRTLE STREET, LIVERPOOL, 7

Applications are invited for the post of Biochemist (Senior Grade) in the Pathological Department of the Institute First- or second-class honours degree essential. The appointment includes both routine hospital biochemistry and work connected with the investigations into the uses of radioactive isotopes in medicine Ample opportunity and facilities are available for work of a research nature into the problems of the biochemistry of neoplastic disease. Salary and conditions of service in accordance with the recommendations of the Whitley Council.

Applications, stating age, qualifications and experience, together with the names and addresses of two referees, to reach the Secretary by September 29, 1956

UNITED OXFORD HOSPITALS

A Physics Graduate is required in the Department of Radiotherapy The Department is expanding and the work will include developments connected with rotation therapy, multicurie cobalt units and the use of radioactive isotopes. Some research facilities will be available but candidates should be interested in a career in hospital physics Previous hospital experience is not essential and candidates taking degrees this year will be considered. Initial salary will be on the National Health Service (£475 to £625) Probationary scale according to qualifications and relevant experience.

Applications, giving full details and names of two referees, should reach the Assistant Administrator, Churchill Hospital, within two weeks from the date of this advertisement.

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

Applications are invited for the post of Temporary Research Assistant in the Physiology Department to carry out research on the assay and physiology of prolactin Applicants should hold a good honours degree, preferably in biochemistry, and should possess a good biological background The appointment is for a year in the first instance. Salary within the range £650 to £850 per annum according to qualifications.—Applications, with names of two referees, to the Secretary, N I R.D, Shinfield, Reading Quote reference 56/10.

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Lecturer in the Department of Metallurgy at an initial salary within the range £650 to £1 350 per annum, according to qualifications and experience The successful candidate will be required to lecture in x-ray metallography and thermodynamics of alloys.

Applications stating age, qualifications, and experience, together with the names of three referees, should be received not later than October 6 1956, by the undersigned, from whom further particulars of the conditions of appointment may be obtained

STANLEY DUMBELL,
Registrar

NATIONAL VEGETABLE RESEARCH Station requires Scientific Officer (honours graduate) in Plant Pathology Section to work mainly on seed-borne diseases Starting salary according to age and experience in scale £565 to £995. Superannuation under F S.S U.—Applications (four copies), giving three referees, to the Secretary N V R S. Wellesbourne, Warwick, by September 29, 1956

CYCLOTRON ENGINEER OR PHYSICIST

Graduate in light electrical engineering or physics required to work on cyclotron at Hammersmith Hospital. Opportunities will be provided for gaining experience in engineering mechanics, including cyclotron beam measurements, high vacuum work, target design and ion source development The appointment will be Grade IV Scientific Staff, £500 to £690 per annum.—Write, stating age, academic qualifications and experience, to Senior Cyclotron Engineer, Medical Research Council, Hammersmith Hospital, Ducane Road, W 12

UNIVERSITY COLLEGE HOSPITAL

Gower Street, W C 1

Applications are invited from biochemical or chemical graduates for the post of Research Assistant in the Department of Clinical Pathology.

Apply to Administrator and Secretary

UNIVERSITY COLLEGE

IBADAN, NIGERIA

Applications are invited for appointment to the Chair of Agriculture from candidates with suitable experience in agricultural teaching or with high scientific qualifications coupled with interests in the field of agriculture. Salary £2,450 per annum. Appointment to retiring age (normally 60). Child allowance £50 per annum per child resident in Nigeria (maximum £150 per annum), or £100 per annum per child resident elsewhere (maximum £300 per annum). Part furnished accommodation at rent up to 7 7 per cent of salary Passages for appointee, wife and up to three children under 11 years on appointment, overseas leave and termination F S S U. Outfit allowance £60

Applications (6 copies), detailing qualifications and experience, and naming three referees, by October 9, 1956, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

GOVERNMENT OF CYPRUS GEOLOGICAL SURVEY

PALAEONTOLOGIST

Qualifications · first- or good second-class honours degree in geology and at least six years' postgraduate work in palaeontology and a fair knowledge of micro-palaeontology Duties · To identify fossils and micro-fauna in order to determine the age of sedimentary formations To assist in the mapping of fossiliferous horizons. Other suitable duties as assigned by the Director Terms of appointment: On contract for four years in the first instance with salary according to experience in the scale £1,236 to £1,548 per annum, plus overseas allowance of 20 per cent of salary. Cost of living allowance of 11½ per cent of salary. £30 outfit allowance Gratuity Free passages Quarters provided at rental Generous leave Income tax at local rates. Free medical attention.

Apply to Director of Recruitment, Colonial Office, London, S W 1 State age, qualifications, and experience, quote BCD 105/17/03.

UNIVERSITY OF EDINBURGH

MEDICAL PHYSICS UNIT

Applications are invited for the post of Director of the Medical Physics Unit with status of Senior Lecturer. This Unit is being established jointly by the University and the South-Eastern Regional Hospital Board, Scotland Salary scale £1 750 by £100 to £2,250 per annum, with superannuation benefit and where applicable, family allowance

Further particulars may be obtained from the Secretary to the University, Old College, South Bridge Edinburgh with whom applications, giving the names of three referees, should be lodged by November 1, 1956

SENIOR SCIENTIFIC OFFICER REquired by the Atomic Weapons Research Establishment, Aldermaston, Berks, to carry out scientific planning of overseas trials of atomic weapons and to co-ordinate the scientific effort of all groups participating in the trials. Duties will also include liaison with Service and Civil departments and will involve short periods of duty overseas Applicants should hold a first- or second-class honours degree in a scientific subject and should have had experience in field trials of Service on prototype equipment. Salary £1,155 to £1,355 per annum Contributory superannuation scheme A house or assistance towards legal expenses on house purchase may be available for married officers living beyond daily travelling distance.—Requests for application forms by postcard to the Senior Recruitment Officer at the above address Please quote ref. A 1094/34

UNIVERSITY OF OXFORD

UNIVERSITY DEMONSTRATOR IN BIOCHEMISTRY

The University proposes to appoint a Unive
Demonstrator in Biochemistry from Januar
1957, or as soon as possible thereafter,
stipend in the scale £750 by £50 (at age 29
£1,100 by £100 to £1,200 by £50 to £1,450.
stipend is in the scale £1,000 by £50 to £1
if the demonstrator is medically qualified M
bership of F S S.U necessary. Allowance of
per annum for each dependent child.

Applications (four copies), stating age, qu
cations, and experience, and giving the name
two referees, to Professor H. A Krebs, De
ment of Biochemistry, South Parks Road, Ox
from whom further particulars may be obta
not later than October 31, 1956

UNIVERSITY OF BIRMINGHA

DEPARTMENT OF MECHANICAL ENGINEERING

Applications are invited for the post of
turer (Grade II) in Mechanical Enginee
Candidates should have an honours degre
engineering, together with practical engine
experience and an interest in research S
scale £650 by £50 to £1,350, with efficiency
at £900, according to qualifications, plus F S
and family allowance

Applications should reach the Registrar,
University, Birmingham, 15, from whom fu
particulars may be obtained, not later than
tember 30, 1956

G. L. BARNES,
Secreta

Birmingham, 15

RESEARCH FELLOWSHIPS I GOVERNMENT SCIENTIFIC ESTABLISHMENTS

The Civil Service Commissioners invite a
cations for a number of Senior and Junior
search Fellowships, tenable for three years
Government Scientific Establishments, for rese
into subjects of importance to H.M Gov
ment There are no age limits but candid
must normally have a first- or second-
honours degree in an appropriate subject
must be able to show evidence of a very
standard of ability in research. At least
years' postgraduate experience will be expe
of candidates for Junior Fellowships and at
three years of candidates for Senior Fellows
Exceptionally a candidate without the acad
requirement, but who can produce evidence
outstanding ability in research, may be adm
Remuneration will be according to indivi
merit and experience, at rates between £1
and £1,200 for Senior Fellowships and betw
£650 and £850 for Junior Fellowships F S.
Scheme applies. The fields of research in w
Fellowships may be awarded if candidates of
requisite high quality present themselves cov
very wide range, and Fellowships may be ten
at any of a considerable number of Scie
Establishments.

Further information and application forms f
Civil Service Commission, Scientific Branch,
Old Burlington Street, London, W 1, quo
S.4567/56. Early application advised. In
views held at frequent intervals.

UNIVERSITY OF CAPE TOWN

SOUTH AFRICA

Applications are invited for a Senior Lec
or Lecturer in Chemistry, with special quali
tions in inorganic and/or physical chemi
The grade to which the successful applican
appointed will depend on qualifications and
perience The salary scale is · Senior Lect
£1,200 by £50 to £1,450 per annum, Lect
£850 by £50 to £1,150 per annum. Ther
also a temporary cost of living allowance f
married man (at present £234 per annum)

Applications (with copies of testimonials) sh
state age, experience, qualifications, and rese
work completed or in progress, and give
names of two referees whom the University
consult Two copies of the application and
monials should reach the Secretary, Associa
of Universities of the British Commonwealth
Gordon Square, London, W C 1 (from w
memoranda giving general conditions of app
ment and information concerning the depart
should be obtained) not later than October
1956 An additional copy should be sent d
by air mail to the Registrar, University of C
Town, Private Bag, Rondebosch, Cape T
South Africa, by the same date The Unive
reserves the right to appoint a person other
one of the applicants or to make no app
ment.

FUTURE OF THE BRITISH ASSOCIATION

WHILE it is true that of recent years there has been a growing amount of criticism of the ritish Association, much of that criticism has come om within the Association itself. As such it reflects e effort of the Association to adjust itself and its nctions to serve more effectively the needs of the esent time. Moreover, as Mr. Ritchie Calder oserves in an article on the Association (see 664 of this issue), since the Association, more than y other scientific body, brings the whole range of ience within its scope and at the same time provides forum for discussion with the public, its proceedings ve in consequence inevitably mirrored the com-exities of modern science and the confusion of the y attitudes to science.

Mr. Calder's article, however, is concerned mainly set forth the new conception of the functions of e Association which has emerged from the work of e influential committee under the chairmanship of r Ben Lockspeiser appointed by the Council early is year to consider the functions of the British ssociation in the present-day world and to explain e way in which the Association works. The annual eeting of the Association is unique among scientific eetings in Great Britain both in range and in size, d the Lockspeiser Committee was concerned in the st place with re-defining the function of these eetings. There is likely to be little dissent from the ree broad objectives which the Council in conse-ience set forth in a statement issued at the Sheffield eeting. There is manifestly need for a platform in ich leading scientists can discuss their work in all theoretical complexities so that the public may derstand the integrity and discipline involved in e search for scientific knowledge for its own sake d, even if only incidentally, something of the nditions in which alone creative work is fruitful or en possible. No less apparent is the opportunity ich the very structure of the Association affords checking the excesses of specialization and the gmentation of science, which have separated ientists working in different fields and made them most unintelligible to each other, by bringing them gether in joint sessions so that they can share perience in related fields and recognize problems the frontiers of present knowledge. Lastly, and keeping with its consistent and unique tradition, e British Association must meet the needs of non-ecialists, whether they be scientists outside their n field or interested laymen.

It is not suggested that this is the order of relative portance of these three objectives, but all three e objectives which probably no other body is in so od a position to serve as the British Association, ovided it enjoys the full support of scientists them-ves and has at its disposal the necessary resources. e real problems arise in the field of technique, rticularly of organization and of communication. e latter, as Mr. Calder notes, may well involve ch fuller use of the instruments of mass-communication and the acceptance by scientists of some guidance by the Press and by broadcasting and television experts as to the most effective method of popular presentation of scientific material. The former, as the statement of the Council indicates, involves some measure of conscious planning of the Association's meetings.

The Council is clearly aware of some of the difficulties and of the value and importance of consultation with the Press, radio and television authorities. For the Association to discharge such functions to-day much more is involved than changes in the education of the scientist himself which will both widen his outlook and enable him to interpret his work more effectively to fellow scientists working in other fields and to the interested layman. The conflict of time-tables and interests, for example, which, as Mr. Calder points out, at present hinders full use being made of the opportunities of widening interests already to be found in the Association's annual meeting, will not be removed without the full understanding and co-operation of the several sections and their officers. The Programme Co-ordinating Committee which the Council has now to set up to supplement the work of the Section Committees is unlikely to succeed in ensuring a balanced programme for an annual meeting as a whole unless the purpose of such co-ordination is widely understood and appreciated in the sections.

There will be the more confidence that such planning by consent will be effective in that so much of the constructive criticism has come from within. It may be recalled that three years ago, at the Liverpool meeting, Dr. W. E. Swinton in his presidential address to the Assembly of Corresponding Societies subjected the functions of the Association and the Assembly and its constituent societies to a critical re-examination in the light of the environment and the climate of opinion in which they are set to-day (see *Nature*, 172, 782; 1953). At Sheffield, while Sir Raymond Priestley in his presidential address referred to the serious study now being made by the Association as to how best it could discharge its responsibilities in the circumstances of to-day, and asserted that its functions of integration and dissemination were more important than ever, Dr. F. J. North in his presidential address to the Assembly of Corresponding Societies reviewed critically the place of the local society in the community of to-day.

This particular address was indeed the subject of a subsequent discussion and should be noted for its bearing on what Mr. Calder suggests is an even more important aspect of the proposals for increasing the influence and effectiveness of the Association. The local societies are continuing bodies which to be effective must meet at regular and frequent intervals if they are to maintain close touch with the community. The British Association meets only once a year, and the Council is conscious that other forms of service are required to give continuity to its efforts. It suggests that there is a place for a suitably planned and presented non-specialist scientific journal, and since it is imperative that scientists and laymen should be seen to accept the need to foresee and debate the social and political consequences of science, it suggests also that prominent industrialists and political leaders and others should be invited to contribute to sessions not only at the annual meeting but also at special one-day meetings on specific subjects.

Such suggestions are not in fact new. The British Science Guild was formed more than a generation ago for much the same purpose, and since 1938 the Division of Social and International Relations of the Association, which at the discretion of the Council can meet anywhere, at any time, on any appropriate subject, has provided the means for such meetings of the Association during the year. Financial difficulties and the lack of adequate staff have severely restricted the meetings of the Division, however, since the War. A powerful new Committee has now been appointed, and it is proposed that during the year the Division should meet industrialists, farmers, administrators, trade unions, women's organizations and any other sections of the community whose interests are affected by science.

While in this way the Association may well establish contact with new sources of membership, this development should not be considered in isolation from the other proposals affecting the annual meeting. For one thing, the majority of members, in the future, as in the past, are likely to be scientists, and the solution of the problem of making the Association more effective depends at least in part in making the Association more attractive to scientists themselves and in particular in drawing to its meetings more of those age-groups and occupations which at present are largely absent. It is generally agreed that at the Sheffield meeting there was a larger proportion of those aged under thirty than in recent years. The bulk of the members attending the annual meetings are either under thirty or in the older age groups. The middle-age groups, which provide most of the active research workers and leaders of research teams, are usually absent, and the industrial scientist, if persuaded to present a paper or participate in a discussion, usually arrives just in time for his session and hurries away directly it is over. Often enough he has not even paused to consider whether or not the programme offers him a noteworthy opportunity to learn about or discuss advances or trends in some discipline other than that in which he is immediately concerned.

One of the first tasks of the new co-ordinating committee is, by tactful persuasion and consultation, to influence decisions on the main topics to be discussed at the annual meetings, at least to the extent of reducing the number of trivial and disconnected papers and increasing the number of more fruitful meetings at which specialists in different branches of science and laymen with varied interests can discuss questions requiring illumination from different directions. For this purpose the Association must be in close touch with scientific opinion in general. As has been observed, the British Association i a unique institution, and its traditions hold muc of value which should still help to determine it functions. Moreover, the character of professiona and scientific institutions generally is changing an in the past generation fairly rapidly. Against th proliferation of small societies must be set th growing size of the major bodies which increasingl robs them of the intimate and social character the once possessed.

Whether or not the mounting costs of publicatio will set limits to the proliferation of societies it i unlikely that the growth of the major institution will be halted. They are likely to be increasingl used by the Government and other bodies for consultation in professional and technical matters an to provide the most convenient and appropriat channels for co-operation with like institution abroad or for international action in professional o technical matters within their competence. Frequently they may come to be looked upon b their members rather as qualifying and publishin bodies than as societies requiring service from thei members.

Such tendencies may well make the new role forecast for the British Association even more importan and at the same time widen the opportunities for i to summon scientists to this twin duty of integratio and dissemination. While the Association itself is a the moment primarily concerned with improving th mechanics of the Association, it is unlikely that ther will be any halt in the efforts which in recent year have been made, within and without the Associatio to raise the general standard of scientific expositio and to devise improved methods of general educatio both for the scientist and for the non-scientist. Th Association may well with profit discuss such matte again in the future. For the moment it must concentrate on making its meetings as attractive a possible to the widest range of scientists and layme having regard to the limits which are inevitably se by any one place of meeting, and to ensure that th organization and timing of the meetings reall permit those attending them to take the fu advantage of them at least in relation to the thre specific objectives of the whole annual meeting.

If this is to be done it means that the Associatio must attract to its meetings not merely more of th younger scientists and lively minds of the youn generation but also a continuing reasonable proportion of leading scientists and technologists wh count it worth while to interpret their work an thought to such an audience and to discuss wit other specialists its social and political as well as it scientific or technological implications. A highe proportion of the middle-age groups of scientists an technologists is also desirable. Clearly this mean good publicity as well as a carefully planned an well-arranged programme of specific and majo topics. It involves also adequate finance. As S Raymond Priestley observed: "We have to mak our meetings so attractive that our membershi taxes the accommodation of the great cities in whic we meet. At the same time, we must convinc ndustry that we have a task worth doing and are equal to that task".

The Council's statement shows clearly that the British Association is fully alive to its changed responsibilities and new opportunities in the world of to-day. Given the support of scientists generally which the new proposals fully deserve, the Association may well make an even greater contribution to the ife of the nation than it has done in the past, provided only the handicap of inadequate financial resources is removed. If, however, the support of ndustrial or other benefactors is to be attracted on a large scale the programme of the Association must contain the large specific projects which manifestly compel the attendance and support of leading ndustrialists, scientists and administrators themselves and justify an industrial firm or other organzation sending its young people to attend the meetings. Its educational functions could well ustify support from Government sources; but the support from industry and commerce alone which an appropriate programme could attract would be much more worth while and in itself might remove the difficulty which since the War has handicapped so severely the Association and especially its Division of Social and International Relations.

PAVLOV AND HIS CONCEPTS

Selected Works

By I. P. Pavlov. (Edited under the supervision of Kh. S. Koshtoyants.) Pp. 654. (Moscow: Foreign Languages Publishing House; London: Central Books, Ltd., 1955.) 10*s.* 6*d.*

IT is fifteen years since any of Pavlov's major writings were issued in an English translation, so the publication of an English edition of a selection of his works is something of an event. The book acket claims this to be "the most representative selection of Pavlov's works yet published in English". In one sense only, namely that it includes publications on all the subjects on which Pavlov worked and from every period of his life, is this true. It is unfortunate, however, that the book gives no clue to the fact that rather more than two-thirds consists of a selection of lectures and addresses already published in English long ago. This section of the book therefore needs no comment. Among those which appear here for the first time in English are three papers on "The Accommodation Mechanism of the Blood Vessels" (1877), on "Digestion" (1899), on "The Trophic Action of the Nervous System" 1920) and a minor article dated 1936 on "Voluntary Movements". There is also a paper (1938) on "The Theory of Types", two on "The Problem of Sleep" of the same date and two on "The Experimental Pathology of the Higher Nervous System". These last two cover much the same ground as a paper read in the same year to the Second International Congress of Neurologists in London and published in 1941 in New York as Chapter 56 of Prof. Gantt's translation of Pavlov's writings on "Conditioned Reflexes and Psychiatry". New material also includes a collection of ten public peeches and addresses, mostly quite trivial, and a hree-page autobiography almost completely lacking in interest. The translation is reasonably adequate. The production is unattractive; but the price is very low. There is no index.

There are two other parts of the book which are both new and interesting: an introductory essay by Prof. Kh. S. Koshtoyants on "Pavlov and the Significance of his Works"; and the concluding section, consisting of about seventy pages of translations of stenographic records of selected statements made at the 'Wednesday' gatherings. These 'research seminars' were held from 1921 until 1935, and minutes were apparently kept for the last six years. Three volumes of these records were issued in the U.S.S.R. in 1949; but the fragments here given constitute the only translations so far published. It is thus to the first and last sections of the book that we must look for new material and for a clue as to the *raison d'être* of the publication as a whole.

The introduction contains some material of historical interest and is of some value in relating the development of Pavlov's work and of his views to the general attitude of mind of Russian (and by no means only Russian) biological science at that time. The real danger to the scientific study of behaviour presented by the subjective psychology of that time is made clear and Pavlov's violent reaction to it intelligible, and in this introduction some of his true greatness emerges. But unfortunately much of the introduction is taken up by bombastic statements about Pavlov's influence and achievement. Thus (p. 22) "Sechenov's basic postulate that the organism cannot exist without its supporting external environment is experimentally proved and in a way rounded off by Pavlov's theory of conditioned reflexes". Pavlov is given lavish praise for his naïve ideas on the second signalling system (merely a crude physiological scheme to account for the symbolism of human speech). We are told that "they point before his followers new avenues of research in the sphere of the physiology of the higher nervous activity, the way indicated to future generations of physiologists by their great teacher". Finally, on pp. 36–37, we read that because of Pavlov "it proved possible for the first time in the history of science to apply the precise method of investigation of natural science to the highly complex phenomena of the so-called psychical activity in man and animals", and this is why "it encountered the animosity of a number of scientists and idealist philosophers, lackeys of the imperialistic bougeoisie"—among whom are apparently numbered Sherrington, Lashley, Wolfgang Köhler and Woodworth! This kind of pathetic claptrap has been only too familiar in Russian writing in recent years, and there is, of course, the very real excuse for it that it was no doubt produced under a sense of extreme political threat. If, as we hope, the Russian sense of humour is now being freed from some at least of its chains, we may be sure that such writing will soon be treated with the same contempt and derision inside the U.S.S.R. that it has always received outside.

The final section (12), the "Records of the Wednesday Gatherings", is the most interesting part of the book. These fragments have apparently been chosen to show Pavlov's unswerving enmity to anything considered to be non-Marxist in science. This is a sad disservice to the memory of Pavlov, since it merely shows his worst side and makes him appear a petulant, intolerant and narrow-minded pedant. In fact, we know from his biographers that, although often appearing an irritable martinet, underneath he was a jovial, lovable enthusiast who, whatever his defects and whatever anyone else did, was enjoying himself hugely throughout his long life and was (to quote Rebecca West) "feeding his investigatory reflex like a king and filling it full of the good factual cheer it wanted".

The confusion of thought exhibited in some of the charges against men such as Sherrington, Köhler and Lashley is indeed a sad commentary on the limitations of a very great man and makes weary reading. But to students of the psychology of genius and still more of the philosophy of science they are extremely instructive. Wolfgang Köhler's "Mentality of Apes" and Sherrington's Rede Lecture "The Brain and its Mechanisms" come in for particularly severe criticism. Let us take the attack on Sherrington as perhaps the most fundamental and illuminating. The Sherrington booklet certainly has some obscure sentences, but Pavlov seems out for deliberate and blatant misrepresentation; and I believe that all this confusion is due to Pavlov's own gradually growing mental muddle over the meaning of the term 'reflex' and that it has an important lesson for present-day students of scientific method. The original idea of the reflex was simply an observed, consistent correlation between stimulus and response; using the last two words in a simple physiological sense. Obviously when receptor and effector are distinct and in different parts of the body, some form of conduction mechanism has to be postulated. Sherrington, like so many neurophysiologists before and since, was concerned with relating the characteristics of reflex response to a supposed elementary nervous conduction mechanism—the reflex arc—and it is upon the inclusion, within the reflex concept, of the idea of some such simple conduction mechanism that its usefulness as a physiological term really depends. Regarding the synapse as a physico-chemical system, Sherrington was, of course, trying to see how far the various characteristics of the reflex—summation, facilitation, latency, refractory phase, after-discharge, inhibition, post-inhibitory rebound—could help in accounting for the behaviour of the animal when a large number of such reflex arcs became integrated to form units of the higher nervous system.

To say that Pavlov was not a neuro-physiologist in the strict sense at all is in no way to belittle his great achievement. Strangely enough, he was, in his behavioural work, a psychologist, since he was concerned with investigating the laws governing relations between stimulus and response but not really interested in the possible mechanism intercalated between them as expressions of the known properties of neurones, the characteristics of conduction and of the synapse. Thus, as Konorski[1] (who has done more than anyone to relate the work of the two) has pointed out, his theory was essentially an anti-neurone theory. Nevertheless, all the time he undoubtedly had the idea at the back of his mind that, since a reflex arc is a physiological mechanism, the use of the term reflex itself made his work physiological and thereby gave it greater scientific reliability. So he was wont to attack not only the old introspective psychologists, some of whom no doubt deserved it, but all physiologists who saw that the known reflex-arc mechanism was inadequate as the sole basis of animal and human behaviour. He was quite unable to see that, as von Holst[2] says, there may be many mechanisms with other modes of function within the nervous system. "We merely recognize fragments of some of them and call them reflex; but this term denotes fragments of very different mechanisms." Yet Pavlov continually widened his own use of the term reflex (see his writings, of almost unbelievable naivety, on "the freedom reflex", the "reflex of life", and the "reflex of purpose") until gradually it came merely to mean 'response' and then finally meant practically nothing at all! He also spoke of "purposive acting science" of the dog having "the idea of food", and used other similar phrases in reference both to human and animal behaviour. He even spoke of an animal "aspiring to the attainment of a definite exciting object" ("Lectures", 1, Ch. 27, p. 276). Yet he repeatedly refused to allow that there was anything in behaviour except stimulation from the exterior. But, as Agar[3] has shown, he really planned his experiments, as we all do, simply by trying to set up situations which he hoped would yield fruitful results; and in devising such situations, he was constantly guided not by considerations of what may happen in the cortex but by the knowledge of human mental processes. "The tacit, and of course correct assumption underlying the plan of the classical Pavlov experiment is that in order that the dog may learn that the sound of the whistle means that food is coming, experience of the sequence silence–no food is as necessary as the sequence whistle–food. The reason for planning the experiment on this assumption can only be the recognition that we ourselves would have no ground to base an anticipation of food following the sound of a whistle unless we were able to compare the two experiences of silence followed by no food and sound by food."[3] So there is no reason for the oft-expressed statement that this method of biological investigation of behaviour possesses greater validity or is more physiological than any other method purporting to deal with memory, judgment, perception, etc. Both types of investigation must be carried out scientifically, and both must be judged by their results.

Marxists, of course, do not officially deny the effective existence of mind; but they do deny the dualism of mind and matter, and hence, calling themselves materialists, often come to speak as if mind is by definition something less important than matter. Pavlov was in effect, and of necessity, just as much a dualist as any of those he criticizes, probably more so than some of them. Over this he is ambiguous. At times ("Lectures", 2, Ch. 45) he appears to be a thorough-going mechanist, speaking as if he believes physiology can look forward eventually to absorbing psychology. Elsewhere ("Lectures", 2, Ch. 54) he denies being a mechanist and comes to admit, albeit rather confusedly, that he is a dualist. But Prof. Koshtoyants will not admit the fact. There is a highly significant mistranslation of Pavlov on this point in the book under review. In the 1941 standard edition of Vol. 2 of "Lectures on Conditioned Reflexes" ("Conditioned Reflexes and Psychiatry", Lawrence and Wishart, London) on p. 149 (also quoted in the introduction, p. 24) Pavlov says: "I wish here to emphasise the incoherence, the absurdity of a reconciliation between the subjective and the mechanical state. For me there is here a gross misunderstanding." This paper was published originally in French, and I have confirmed that this translation is correct. But Koshtoyants's edition, p. 546, makes Pavlov say: "they [his opponents] want to stress as strongly as they can the obvious inaptitude and absurdity of trying to link subjective feelings and mechanics. In my view this is an obvious misunderstanding”.

As a result of all this confusion, Pavlov burdened himself with a series of verbal subterfuges which are now seen to make nonsense. Worse still, he fastened these upon his followers in the form of a terminology which hindered a whole generation of them from going forward to tackle the really interesting problems which he had the insight to see were awaiting them. The modern development of elaborate cybernetic mechanisms as analogical tools for the study of the higher nervous centres is a very important one and likely to be of great service. Psychologists in recent decades have tended more and more to neglect the old concern with thoughts, feelings and sensations and to suspect introspection. There are good historical and other reasons for this. But consideration of brain models and of Pavlov's concepts brings one back again to the fundamental question whether, if one is concerned to understand behaviour, one is following the best course when one neglects altogether, to quote Tustin[4], the “one privileged access available to such immediate precedents and accompaniments of behaviour as thoughts and feelings, that are part of the complex of events of which behaviour is also a part”. The usual way of escape is to fall back on the precious word ‘complexity’ and to assume that, because of its complexity, the brain is conscious and that a machine elaborate enough to maintain an inner representation of the outer world may thereby be conscious. But, as Tustin says, this is no explanation. For to regard consciousness as an emergent does not merely fail to explain consciousness in terms of assumed elementary physical mechanisms; it assumes that it is inexplicable on that basis. This is the kind of fundamental theoretical difficulty which was the basis of Pavlov's confusion, as it is of many to-day. As Whitehead says, science must be continually criticizing its own foundations if it is not to be in danger of developing into a medley of *ad hoc* hypotheses.

AUTOMATIC CONTROL AND MACHINES

Automation

Friend or Foe? By R. H. Macmillan. Pp. viii+100+8 plates. (Cambridge: At the University Press, 1956.) 8*s*. 6*d*. net.

THIS small book of approximately twenty-four thousand words is based on the author's series of B.B.C. broadcasts, on automatic control and automatic production, in the Third Programme. In the introduction the meaning of the word automation is described as automatic production and the striving for a fully automatic factory. From the rest of the book it becomes obvious that the only new discovery in the past decade in this field is the word, automation itself. The three branches of engineering science which must combine to make automation possible—namely, automatic control or servomechanism theory, mechanization of production, and electronic digital computers—are dealt with in four of the six chapters of the book. The remaining two are devoted to economics and future prospects.

The theory of control systems, which is the author's own field of research work, is introduced by a historical sketch of various automatic mechanisms from seventeenth-century pressure cookers to mid-twentieth-century naval gunnery. The development of the understanding of these various individual mechanisms into a fundamental science is brought out by discussing some of the famous theoretical personalities—Maxwell, Routh and Nyquist—who have contributed greatly to the theory of servomechanisms. The aim of this section is to bring out in non-technical language the concept of feedback. The essence of the section on production can be summed up in the two phrases ‘line production’ and ‘transfer machines’. These are methods established in the 1920's. Automatic computers are dealt with in Chapter 5, again on a historical basis. Pascal (1642), Leibniz (1673) and Babbage (1829) are given as the early forerunners who laid down the basic principles of the modern high-speed electronic counterparts. Sufficient emphasis is not given to the major developments by ingenious inventions of large-capacity storage of data with, at the same time, rapid access to any required piece of stored information. Analogue computers are also mentioned and incorrectly termed ‘simulators’ (p. 63). The reader is also left with the erroneous view (p. 73) that, in general, the analogue computer is much faster than the digital machine.

The chapter on economics is weak; only the factors affecting the installation of equipment are considered. The overall economy, including the treatment of labour redundancy, is not dealt with. On reaching the last chapter, on “Present Impact and Future Prospects”, one is disappointed to find that it does not deal with the book's provocative title but is devoted exclusively to the expansion of the feedback concept of the control engineer into other sciences such as physiology, biology, zoology, theory of economics, etc.

This is a very interesting and well-written book which does not demand any scientific knowledge of the reader. It is a great pity the contents are not covered by the title.

John C. West

ELECTRONICS IN PHYSICS AND ENGINEERING

Advances in Electronics and Electron Physics

Edited by L. Marton. Vol. 7, 1955. Pp. x+527. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 11.50 dollars.

THE seventh volume in this now well-established and excellent series of specialist review articles contains much the same blend of physical and engineering electronics as its predecessors; but there is a somewhat stronger emphasis on related solid-state phenomena. The contents consist of seven independent reports of advances in widely different branches, ranging from semiconductors to radio astronomy. The reports vary in length from forty to a hundred pages, and each includes a very extensive bibliography of well over a hundred references. The “Advances”, like the many other similar annual reviews of individual branches of science, fulfil a very important function in these days when the volume of published research is so extensive. Each article is a model of clarity and conciseness, containing a wealth of up-to-date information, and is compiled by authors who have obviously a first-hand knowledge of their subjects.

Two articles—the physics of semiconductor materials, by E. Burstein and P. H. Egli (Crystal Branch, United States Naval Research Laboratory), and theory of electrical properties of germanium and silicon, by H. Brooks (Harvard University)—summarize our present knowledge of the nature and structure of semiconductors, including the recent substantial progress that has been made in the determination of the energy-level structure of the valence-type semiconductors. E. Rudberg in the early 1930's clearly demonstrated that when slow electrons impinge on solid surfaces there are characteristic values of energy losses that form a kind of line spectrum of the energy distribution, for which he coined the expression "characteristic energy losses". The last few years have seen rapid development in the observation and interpretation of these energy losses, and the article by L. Marton, L. B. Leder and H. Mendlowitz (United States National Bureau of Standards) describes the wealth of information acquired.

This is followed by an article on sputtering by ion bombardment, by G. K. Wehner (Wright Air Development Center), a phenomenon which is little understood owing to lack of reliable quantitative yield data. The report on electrical discharge in gases and modern electronics, by L. Goldstein (University of Illinois), is confined to a survey of work during the past ten years and deals with the fundamental processes occurring in the volume of low-pressure weakly ionized gases at ordinary temperatures, using the new experimental techniques involving high-frequency electromagnetic fields and microwave methods.

The two remaining articles deal with widely different branches of electronics—observational radio astronomy and analogue computers. The first summarizes the main results concerning the Sun, our galaxy and external galaxies, and the observational methods used for studying the universe at radio frequencies, together with the physical and astronomical significance of the radio observations. The second is concerned primarily with the advances during the past five years in analogue computation, though a short historical summary is given of computer developments since the Second World War. Various sections deal respectively with components; computer systems, the larger of which such as TRIDAC and TYPHOON were developed for the solution of problems in guided missiles; and a variety of uses to which analogue computers are now being put. S. WEINTROUB

SCIENTIFIC BACKGROUND OF TANNING

The Chemistry of Tanning Processes

By K. H. Gustavson. Pp. ix+403. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 9 dollars.

FROM time immemorial animal skins have been transformed by the tanning process into the fibrous and biologically stable product, leather. Recent research in the chemistry of tanning materials, proteins and the reaction between proteins, and substrates of small molecular weight, now permits the scientific investigation of tanning action and a critical appraisal in book form of this progress should therefore prove opportune. This book by K. H. Gustavson deals with the chemistry of chromium salts and chromium tannage, the effect of neutral salts and complex-forming agents in chromium tanning, miscellaneous factors in chromium tanning, the nature of the chromium–collagen complex, vegetable tannage, the reaction of lignosulphonic acids and syntans (synthetic tanning agents) with collagen, aldehyde tanning, quinone and oil tannages, combination (chromium and vegetable) tannages, and some tanning reactions of biological and medical importance.

In the first half of the book, the author approaches chromium chemistry and tannage through the agency of electrometric titration, ion-exchange chromatography, ionophoresis and reaction kinetics. The results are interpreted in terms of the ionic and co-ordinate valencies of chromium, and of the functional groups and polypeptide backbone of collagen. Much of the research was initiated by Gustavson, who commands the reader's attention.

The review of vegetable tannins is, however, inadequate and out of date. Recent work (cf. Schmidt O. T., and Mayer, W., *Angew. Chem.*, 68, 103; 1956) has restored order and interest to the untidy field of vegetable tannin chemistry. Of the ellagic acid free hydrolysable tannins, the constitutions of chebulinic acid and hamameli-tannin have now been elucidated, and a tetrasaccharide formula has been proposed for sumach-gallotannin. Among the ellagitannins, the structures of brevifolin, chebulagic acid, corilagin, and dehydrodigallic and valonic acids have also been elucidated. Recent application of conformational analysis to catechin and its epimerides deserves mention.

A lack of appreciation of the chemistry of vegetable tannins, particularly of gallotannin and of the constituents of myrobalans, is reflected in the subsequent treatment of their tanning action. Further conclusions drawn from adsorption experiments involving crude tannin extracts and hide-powder exceed in scope the nature of the experiment. Although the phrase "multipoint contact" is frequently employed, there is no reference to Fischer's (1894) provocative "Einfluss der Configuration auf die Wirkung der Enzyme" which initiated the spate of studies on enzyme substrate-inhibitor and agonist-antagonist relationships throughout the succeeding half-century. This approach to tanning action might have been advantageously developed within the context of vegetable tannage. It is surprising that no reference has been made to the application of reaction kinetics to vegetable tannage, despite its obvious importance, and its successful application to the analogous dyeing of wool. There is an excellent summary of synthetic tanning agents.

The book concludes with a stimulating account of biological reactions which possess a possible tanning implication. The biologists' discoveries require critical assessment, however, as their materials are often detected histochemically by staining reagents. Much of this work awaits intensive investigation by the natural products' chemist. In spite of its limitations, the book is the work of an enthusiast. Its chief merit is that it brings within small compass the salient references in the literature of leather chemistry. D. E. HATHWAY

Yearbook of the Universities of the Commonwealth

Thirty-third Issue. Pp. lix+1925. (London: Association of Universities of the British Commonwealth, 1956.) 63*s*.

THIS useful handbook has been steadily growing in size with each new edition, that for last year being just over two thousand pages. If the new material that has accumulated since then had been incorporated without any adjustment of the existing contents, the present work would probably have been a hundred or more pages longer, and the volume would have been in danger of becoming unwieldy—a fault the magnitude of which is in direct proportion to the frequency with which the book is consulted.

Fortunately, the editor has taken steps to rectify this and, by a slight reduction in the contents, has managed to make this year's edition about a hundred pages shorter than the previous one. The three appendixes in the 1955 edition on postgraduate awards, Anglo-American academic relations and international university organizations, respectively, have been omitted, although the first one is available as a separate pamphlet. In the entry for each university headed "The Year", there are no longer the paragraphs on principal changes in regulations, adult education work, and visits by teachers; furthermore, those on benefactions, new buildings, and new departments and posts have been pruned.

This lopping, not of dead wood, but of branches that were not over-fruitful, has made room for some new growths—notably a new appendix on British academic institutions abroad, and an analysis, in many of the separate university entries, of the distribution of students by faculties. The new appendix covers three institutions: the British Institute in Paris; the British School at Rome; and the British School of Archæology at Athens. Thus it will be seen that the "Universities Yearbook", as it used to be entitled and is still commonly referred to, is very much alive and is likely to flourish for many a year to come.

The Birds of the British Isles

By Dr. David Armitage Bannerman. Vol. 5: Falconidae, Accipitridae, Aegypiidae, Pandionidae. Pp. xiii+350+34 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 63*s*. net.

WITH this fifth volume, Dr. D. A. Bannerman's scholarly survey of knowledge of British birds nears the half-way mark. There is here interpolated a brief memoir and a portrait of George Edward Lodge, the author's artist partner who died after the work had begun to appear. This tribute could not have been more fittingly placed, because his artistry was at its very best when birds-of-prey were his subjects; and within the same covers we have many outstanding examples of his work—incidentally, in several instances more than one plate of a single species, illustrating geographical or developmental differences in plumage.

The whole volume is devoted to the four families of diurnal birds-of-prey—falcons, hawks (in the widest sense), vultures and osprey; and that there are only some two dozen species will give an idea of the extent and detail of the treatment. The author quotes freely from others; but some of their material has not been published before and he has often facts to add from his own observations. Nowhere else would one find together so much information about the migrations and habits of each species, based on study at home and abroad. In respect of this group there is a wealth of observation of spectacular passages in some parts of the world; and the variety of hunting habits is of much interest, including the aerial 'pass' of food from the male to his mate exemplified by Montagu's harrier and by the hobby. The account of British status is too often a sad story of dwindling numbers and of a lost or precarious foothold. The use of certain species in falconry, once "the sport of kings", receives due mention.

LANDSBOROUGH THOMSON

The Number System

By Dr. H. A. Thurston. Pp. viii+134. (London and Glasgow: Blackie and Son, Ltd., 1956.) 15*s*. net.

DR. H. A. THURSTON has two aims in view: he wishes to explain to the intelligent non-mathematician the way in which the number-field is extended from the integers through the rationals to the irrationals and the field of complex numbers; he also wishes to give the student of mathematics a complete logical account of these extensions. He has therefore divided his book into two parts: the first half is a semi-popular discussion of the way in which needs to extend the number system have arisen and have been met, a broad and interesting general survey from which details have been omitted; the second half, similar to Landau's "Grundlagen der Analysis", gives the austere logical development, from the integers founded on Peano's axioms to the rationals as ordered pairs of integers, the irrationals as Cauchy sequences of rationals, and the complex numbers as ordered pairs of real numbers. But the two parts are closely interwoven; serious readers of the first part will surely wish to see a portion at least of the detailed working-out of general principles, while the young student will grasp the occasional logical twists of the second part more readily if he makes constant reference back to the more discursive explanations of the first part. The author has taken great pains with both parts, and does not appear to have fallen between two stools.

T. A. A. BROADBENT

Grignard Reactions of Nonmetallic Substances

By Prof. M. S. Kharasch and Otto Reinmuth. Pp. xxii+1384. (New York: Prentice-Hall, Inc.; London: Constable and Co., Ltd., 1954.) 135*s*. net.

THE Grignard reaction is now a major method in organic chemistry. The range of its application is very extensive, and it has an enormous literature. A real service has been rendered in the preparation of this book.

It is by no means a bare catalogue of reactions and a bibliography, although it includes both. It contains readable statements of the underlying chemistry, brief historical surveys, and (what is valuable) new suggestions on possible reaction mechanisms. Particular attention is given to grouping reactions so as to facilitate reference, and the literature references are very complete. In the case of Russian and Japanese papers, references to *Chemical Abstracts* are also given. The 'normal' reactions are defined in each case, and deviations from them are explained.

The volume is an outstanding contribution to chemical literature which should be available in every organic chemical laboratory, where it is likely to be in daily use. Although the price is high, the book is worth it.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

By RITCHIE CALDER, C.B.E.

EVERY year since the War, criticism of the British Association has been growing, and, forgetting resentments of much that was unfair in the strictures, the Council has decided, with the support of the General Committee, which is the membership body, to "put its house in order". Obviously, however, much more is involved than changing the structure and modifying the practices of a venerable institution, 125 years old. More than any other scientific body, the British Association brings almost the whole range of science within its scope and provides a forum for discussion with the public. To that extent, it has mirrored the complexities of modern science and the confusion of the lay attitudes to science.

When, therefore, the Council instructed an influential Committee, under Sir Ben Lockspeiser, "to consider the functions of the British Association in the present day world", it was in fact asking, in institutional terms, what Sir Raymond Priestley, this year's President, asked more rhetorically: "What can we do to help the world to make the choice which will ensure the survival and further progress of humanity ?"

Perhaps the public and the critics expect too much of the British Association as an instrument for resolving their fears and confusions about science. But that is a tribute to its traditions and to the part which it has played, since 1831, as the meeting-ground and market-place of science. The complaint is about the presentation of science; but, allowing for the perennial faults of obscure, inarticulate and slipshod lecturing at the meetings, the blame does not rest entirely with that institution. The newspapers, radio and television cannot escape their responsibilities. But the British Association can help to remedy, by example, the more obvious defects in the scientists' approach to the public.

That has been recognized by the Lockspeiser Committee in its restatement of functions. It is realized, for example, that the Association can no longer provide a platform for the immediate proclamation of original discoveries. That function has been replaced by the learned societies and the scientific journals; no one to-day would hold up an important announcement until the annual meeting of the British Association. It is also true that one of the purposes of the British Association in its origins—to convince an indifferent public and government that science was important and worth backing—is now superfluous. Other urgent tasks, however, present themselves. To quote the Lockspeiser Committee's report: "Science has brought into being a new world, in which the peace and prosperity of all peoples are increasingly dependent the one on the other—dependent because the units of organization (social, economic, political and national) are larger and their control more centralized; a world whose structure is in this sense more rigid and yet one in which both individuals and nations must respond more flexibly and more frequently to the changing situations forced on them by the discoveries and applications of science. The continuance of science is vital to modern society and this being so continued public goodwill is essential. To ensure this the methods and results of science and the nature o fundamental research must all be better understood by those concerned with Government, industry and business and the public at large. Such understanding is essential because, in any democratic State, an informed public is necessary if valid decisions are to be taken; because the public—as taxpayer and consumer—pays for science; because if, in the future, scientists and technologists are to be forthcoming in the numbers that the nation's wellbeing demands, the public should learn to value the contribution of science and come to appreciate the potential satisfaction and opportunity for service implicit in careers devoted to science; and above all because scientific discovery must be applied for the wellbeing of the nation".

The British Association can make its contribution through its annual meeting, which still fulfils its original purpose of taking science to the people (at least in the big cities which can accommodate its many scientific sections and membership), and it still attracts representatives from every branch of science as well as industrialists, Government servants, agriculturists, teachers and a large representation of the Press, radio and television. The first concern of the Committee, therefore, was the re-definition of the function of the annual meeting.

First: it should offer a platform on which leading scientists can discuss their work in all its theoretica complexities so that the public may understand the integrity and discipline involved in the search for scientific knowledge, for its own sake. Second: it must recognize the dangers of specialization and fragmentation of science which has separated the scientists in the various branches and has made them practically unintelligible to each other and must bring them together in joint sessions so that they can share experience in related fields and recognize problems on the frontiers of present knowledge Third: that it must provide for non-specialists whether they be scientists outside their own field or interested laymen. It should provide an annua stocktaking in intelligible language which will review the progress of science and help to make clear its possible social and political consequences. To thi end, prominent industrialists and political leaders should be invited to contribute to such sessions in order to put their problems in their wider setting.

The functions of the British Association are defined as "integration" and "dissemination". The integration involves bringing the specialists together to broaden their knowledge and their discussions beyond what is now possible in learned societies. The dissemination will involve a much closer relationship with the instruments of mass-communication—Press radio and television—and the guidance of scientists as to how they can best serve or make use of popular presentation. Such reforms are badly needed although they may not suggest the 'revolutionary' changes which some of the critics might have wanted. The Committee, however, has recognized that the influ nce, and indeed the functions, of the British Association depends on its traditions.

The British Association relies on a small and inadequate office staff and upon the unpaid efforts of the officials of its fourteen sections and local officers in the centres of its annual meeting. The sectional committees, responsible for the preparation of the programmes, have persisted in virtual autonomy. The presidents of the sections, selected and honoured for their distinction, are appointed for a year, while the recorders, appointed for five years, and the secretaries, provide the continuity. Sections and section officials are jealous of their rights and privileges and, under the constitution, are entitled to resist any interference or dictation from the Council or the general officers. They are entitled, without reference, to choose their subjects and their speakers. The result is more than three hundred papers, of very uneven quality and content, crowded into four and a half days. Although one of the most important purposes of the British Association is to allow members to widen their interests by moving from one section to another (all meet simultaneously), there is a conflict of time-tables and interests.

During the 1930's the principle of joint discussions, where several sections joined together, was encouraged, and they were conspicuously successful. They have continued since the War, at the discretion of the sectional committees.

Against this background, the difficulties of co-ordination are obvious. Although the proposal of 'conscious planning" was approved by the sections and the membership at Sheffield, there was outspoken distrust of any machinery to produce it. Guarantees had to be given that no pattern would be imposed from the top and that any co-ordinating would be done by persuasion and consultation. The Programme Co-ordinating Committee which has been appointed by the Council will therefore plan by consent. There will also be greater opportunities for advance discussions with Press, radio and television so that better material will be devised and better use made of it.

Perhaps more important than the refurbishing of the annual meeting are the proposals for making the British Association an active body throughout the year. The machinery for this has existed since 1938 in the form of the Division of Social and International Relations which, at the discretion of the Council, can meet anywhere, at any time, on any appropriate subject. Its original Committee (in 1938) included such men as Sir Frederick Gowland Hopkins, Sir Daniel Hall, Sir John Russell, Lord Stamp, Prof. P. M. S. Blackett, Prof. J. D. Bernal, Dr. Julian Huxley, Sir Alfred Egerton, Prof. A. V. Hill, Prof. L. Hogben, Prof. H. Levy, Lord Boyd Orr, Mr. H. G. Wells and Sir Solly Zuckerman. Its chairman was Sir Richard Gregory, and throughout the War, when he was president of the Association for six years, he kept the Association alive (although its meetings were suspended) by organizing conferences through the Division. Some of them, like that on "Science and the New World Order", were historic. International scientists were brought together in London, then subject to air-raids, to discuss momentous issues which are with us to-day, although the thinking about them is not as clearheaded as when the scientists and statesmen discussed them under the ægis of the Division.

Since the War, the activities of the Division have been restricted to occasional meetings or to sessions during the annual meeting. This comparative inactivity has been due to the financial difficulties of the Association and its lack of adequate staff.

A powerful new Committee of the Division has been appointed (and was the group which re-examined the functions of the British Association), and it is proposed that the Division should go out during the year to meet the industrialists, the farmers, the administrators, the trade unions, the women's organizations, and any other section of the community whose interests are affected by science. This break-down into common-ground discussions will give the British Association closer contact with reality and, it is hoped, with new sources of membership and finance. The British Association, like so many other institutions, has come to recognize that modern benefactors will finance specific projects and not, as in the past, endow a generalized ideal.

Given its 'New Deal' and the finances to implement it, the British Association can take on, yet again, a new lease of life.

UNITED STATES PROGRAMME FOR THE INTERNATIONAL GEOPHYSICAL YEAR

By Dr. JOSEPH KAPLAN

Chairman, U.S. National Committee for the International Geophysical Year, National Academy of Sciences

THE idea of international co-operation in the study of our changing physical environment is not new. The importance of geophysical data gathered intensively and simultaneously over large and relatively remote areas of the Earth was recognized in the last century in the conduct of the First Polar Year during 1882–83 and earlier this century by the Second International Polar Year, which took place during 1932–33. The proposed international effort for 1957 and 1958 surpasses in scope, intensity, and geographical coverage these earlier programmes, which were largely limited to the north polar regions and to but a few fields of geophysics.

The principal fields of study during the International Geophysical Year, 1957–58* will be aurora and airglow, cosmic rays, geomagnetism, glaciology, gravity, ionospheric physics, longitude and latitude, meteorology, oceanography, seismology, solar activity, and upper atmosphere rocket and satellite studies.

The proposal that 1957–58 be the time for this major international effort was based in part upon the fact that this period corresponds with a period of maximum solar activity. We shall be able to take advantage of this by a carefully planned series of 'alerts' and of 'special world intervals', occurring on such occasions as expected intervals of unusual magnetic, ionospheric, or auroral activity, days of solar eclipses and of abnormal solar activity, and unusual meteor showers. Special co-operative efforts on a world-wide scale will be made during these intervals to record the many phenomena which react to the complex activities of the Sun.

---

* See Prof. Sidney Chapman's article, "The International Geophysical Year, 1957–58", *Nature*, Jan. 8, 1955, for a summary of the scope, aims, and methods of the project.

The current United States programme, planned and directed by the National Academy of Sciences, includes projects and programmes in all fields of the International Geophysical Year. This programme has considerable geographical as well as scientific coverage: the Antarctic, the Arctic, the Equatorial Pacific, and the continental limits of the United States represent the major regions of activity.

Long-range weather prediction and growth of knowledge of basic weather patterns will be greatly facilitated during the Year by the planned world-wide network of surface and balloon stations. The United States will conduct regular soundings to an anticipated height of 100,000 ft. at stations in Antarctica, the Arctic, South America, and the United States. We shall also maintain a Weather Central in Antarctica to collect and disseminate meteorological data to all interested groups both in and out of Antarctica, providing for the first time in history twice-daily weather maps of Antarctica.

As 1957–58 will be a period of maximum solar activity, scientists participating will develop detailed and comprehensive records in this field by means of systematic observations of the Sun with improved and faster co-ordination of the observing programme of solar observatories. Solar activity will be observed both in the visible spectrum and at radio frequencies. In particular, solar flares will be studied and correlated with changes in the intensities of cosmic-ray showers, ionospheric and auroral disturbances, and geomagnetic phenomena.

During the International Geophysical Year, a spectroscopic observation programme will give the distribution of radiations of the auroral spectrum both geographically and with respect to time during the auroral displays. The visual and photographic observations of the aurora have as objectives the creation of synoptic maps showing aurora distribution at small intervals and the collection of data for statistical studies of aurora with other geophysical phenomena and with solar phenomena. With modern techniques such as the all-sky camera, scientists will fill the gaps in knowledge about the aurora borealis in the Arctic, gather data heretofore unavailable about the aurora australis in the Antarctic, and trace the relationship between the two. The observing stations will be distributed along a longitudinal chain reaching from Arctic North America through Middle and Latin America to Antarctica. Measurements of the intensity of airglow radiations will also be made with photoelectric instruments of high sensitivity.

The source of cosmic rays and their possible effect on other particles and radiations in the outer atmosphere are far from adequately understood. During the International Geophysical Year, scientists expect to gain knowledge of the reasons for the large decreases of cosmic-ray intensity during some magnetic storms, fluctuations in cosmic-ray intensity near sunspot maximum, the world-wide variation of cosmic-ray intensity with the sunspot cycle, and the causes of sudden large increases of cosmic-ray intensity within an hour or less after the beginning of solar flares or chromospheric eruptions.

The ionosphere is studied chiefly by means of the radio waves which it reflects. Vertical incidence soundings will be taken at a number of sites in the United States and oblique incidence soundings both in the United States and in the Pacific area. There will be measurements of sporadic-*E*, backscatter by sweep and fixed-frequency techniques, and experiments in forward scatter. Radio noise and ionospheric absorption will also be measured, and there will be an extensive network of stations to study whistlers.

The United States geomagnetic programme consists of a series of experiments mainly designed to yield facts about the rapid fluctuations in the magnetic field, which are usually accompanied by disturbances in radio-wave propagation and often by auroral displays, and which also increase in number and intensity with an increase in the number of sunspots. To this end there will be a chain of geomagnetic stations stretching across the western United States in an east–west direction, another chain in Alaska in a north–south direction, and a third chain of four stations centred near the geomagnetic equator in South America.

Observations for the more precise determination of longitudes and latitudes will be made at twenty International Geophysical Year stations around the world. Astronomical longitudes and latitudes are obtained by observation of the positions of celestial bodies with respect to the direction of gravity. In the related programme on the position of the Moon, scientists using the Markowitz method will try to solve special problems in astronomy, geophysics, physics, and geodesy concerning universal and ephemeris time, the irregular rotation of the Earth, and the size and shape of the Earth.

The fragmentary nature of knowledge of gravity over vast areas in the oceans, the Antarctic, and the Arctic leaves considerable ambiguity about the shape of the Earth as a whole. The United States has therefore planned to carry out a number of gravitational studies. Gravimeter measurements are to be co-ordinated with the seismic exploration in the polar regions and can be carried out by the same personnel.

Seismological observations and measurements have long been conducted on an internationally co-operative basis. The United States programme includes additional measurements in remote areas, particularly in Antarctica and the equatorial Pacific islands. United States scientists will also attempt to measure linear strain directly with an instrument developed within the past few years by Dr. Hugo Benioff at the California Institute of Technology. There will also be projects to study the L_g phase wave and long-period seismic waves.

A study of motions of the deep currents in the sea, such as the vast exchange of polar water masses with those of warmer oceans, is related to problems of long-range weather forecasting. An island observatories project of the United States oceanography programme will be directed toward gaining an understanding of sea-level changes of both short and long periods and their relationship to other phenomena in the ocean and the atmosphere. 'Operation Deep Current', the other United States oceanographic project, will involve a study of the deep circulation of the water moving northward from Antarctica into and along the bottom of the Atlantic and Pacific and multiple-ship, detailed studies of the areas of convergence and divergence in the North Central Pacific and North Central Atlantic. These studies, as for all programmes in connexion with the International Geophysical Year, are co-ordinated with those of other nations.

The United States programme in glaciology will encompass detailed studies at points in the northern hemisphere and at stations in the Antarctic, as well as reconnaissance observations in the western United States, Alaska, and portions of the Arctic in co-operation with Denmark and Canada.

During the International Geophysical Year three approaches to obtaining direct upper-atmosphere data will be utilized: launching of large rockets from the ground, firing of smaller rockets from balloons and from aeroplanes, and launching of earth satellites. A total of more than two hundred rockets of different sorts will be launched by the United States for geophysical research purposes.

One of the limitations of the conventional rocket programme is that the rocket does not stay at great heights long enough to permit certain important types of measurements to be made. A single successful flight of a satellite will provide us with more observing time in the very high atmosphere than has been provided by all the ordinary rockets that have been fired.

Present plans call for the first earth satellite to be launched from the east coast of Florida at Cape Canaveral. There will be a three-stage rocket assembly to provide the means of placing the satellite in its orbit. When the satellite has reached a height of 300 miles, the last rocket will impel it into its orbit at a speed of about 18,000 miles per hour. The satellite will then revolve about the Earth in an approximate latitude range of about 40° on either side of the equator. Taking into account such factors as the Earth's rotation and the elliptical orbit of the satellite, its displacement will be about 25° for each revolution. This orbit will permit us to record observations over a broad expanse of the high atmosphere, while the latitudinal band-width coverage will permit scientists of a large number of nations to make observations and measurements.

The first satellite will be spherical in shape, about 20 in. in diameter, and will weigh approximately 21·5 lb. About half this weight will be required for the satellite itself, the remainder being available for instrumentation. At its closest point to the Earth it will be between some 200–300 miles distant, and at its farthest some 800–1,500 miles. Once placed in its orbit, the satellite becomes in effect a new celestial body. As such, the first problem becomes its acquisition—those preliminary observations which not only establish its existence in orbit but which also provide data for preliminary calculations of its orbit in order that ephemerides may be calculated and issued. These calculations will permit, first, the concentration of ground stations on the preliminary orbit and, second, the subsequent acquisition of more extensive data on the basis of which the various studies can be conducted.

The satellite programme thus affords an unusual opportunity for the acquisition of information about the upper atmosphere. As in other programmes of the International Geophysical Year, this opportunity is a broad one: the nations of the world will not only observe the satellite but will also participate in the scientific programme. The ground-station scientific programme, in particular, calls for extensive international participation in order to secure maximum advantage from the endeavour. Observations by radio or optical instruments will permit the conduct of important experiments relating to the density of the air of the outer atmosphere, the composition of the Earth's crust and various geodetic determinations. Moreover, it is hoped that other nations will be able to place satellites in orbit during the International Geophysical Year, increasing the amount of data thereby attainable and taking advantage of the interests, activities, and observing stations established during 1957–58 by the many participating nations.

PROGRESS OF CANCER RESEARCH

THE investigations described in the 500-page 33rd Annual Report of the British Empire Cancer Campaign covering 1955 can be divided into four categories, namely: (1) radiology, radiotherapy and radiobiology; (2) pathology and morbid histology and clinical themes; (3) carcinogenesis, statistical and demographic studies; (4) biochemical and biological lines such as those on nucleoproteins, cytogenetics, cytochemistry, steroid metabolism, tissue metabolism, viruses, cytotoxic agents, enzymes and hormones. It should scarcely be necessary to reiterate that in this short review only part of the large amount of research can be dealt with, and secondly that in such a wide field any reviewer is limited by his own experience.

The report affords an interesting cross-section of research at many centres into the vexed question of the relation between cigarette-smoking and cancer of the lung. The present position would seem to be summed up in a most interesting paradox: statistically, the case against cigarettes grows more and more convincing at the same time as, experimentally (at least so far as workers in Britain are concerned), it seems to grow thinner and thinner.

It would seem inescapable in the face of the formidable statistical evidence that cigarette smoke must contain something carcinogenic to the respiratory tract. Yet experimental proof of this is remarkably slow in appearing. At a number of centres the current experiment is to apply, to mouse skin, tar from cigarette smoke made in an apparatus which draws air through the lighted cigarette and condenses the smoke by passage through acetone cooled in a 'Drikold' bath. At none of six research centres have malignant tumours been evoked when the tobacco tar was applied to the mice. (These results are completely at variance with those of Wynder, Graham and Croninger in the United States, who obtained skin tumours in more than half the mice which were painted with tobacco tar.) Neither mice, rats nor hamsters have given positive results; nor have the different fractions from the tobacco tar obtained by separation with solvents shown activity.

It might be suggested that the disagreement with the American reports could depend upon some important difference in the technique of preparation of the tars or in the strain of mice employed for the tests. Since confirmation (or otherwise) of the report of Wynder *et al.* is urgently required, a thorough interchange of information and especially of materials, such as tobacco tars, tar fractions and mouse strains, should be instituted—and perhaps plans for such a liaison are already in process of being devised.

The lung of the rat has been used as the test material in experiments where either tobacco tar, or alternatively powerful carcinogens (benzpyrene, methyl-cholanthrene), were applied directly to the lung after thoracotomy had been performed. In forty-four rats only one carcinoma and seven sarcomas were obtained, indicating that the lung tissue of the rat is resistant to the carcinogenic potency not only of benzpyrene and methyl-cholanthrene but also of tobacco tar; the investigators were aiming at producing lung carcinoma of the type found in man, not at merely inducing sarcoma. None of the tumours was induced by the tobacco tar.

Tobacco tar injected directly into the lungs of thirty-six mice induced a low yield of lung tumour which was not very different from the incidence in the control untreated mice. In another experiment, soot containing nearly 100 parts per million of benzpyrene was used for direct injection into mouse lung. These experiments are not yet concluded; so far, the quantitative incidence of lung cancer could not be described as spectacular. Soot from railway engine funnels contains very little benzpyrene, whereas the soot from diesel engines which are operating slowly contains appreciable amounts of benzpyrene among other hydrocarbons.

The mortality-rates from respiratory cancer in Eire has been the subject of a very interesting investigation into the relation of tuberculosis to lung cancer in that country. Males in rural Eire have a low lung cancer-rate, less than a half of that in rural England. The data quoted afford plenty of material for speculation. For example, why was the Greater London lung cancer-rate (for 1953) 1,710 per million males at ages 45–64 and 4,125 at ages 65–74 years, while the corresponding rates for Dublin remained at 1,650 per million at ages 45–64 and 1,655 at ages 65–74? In 1953 the rate in rural England was 1,140 at ages 45–64 and only rose to 1,665 at ages 65–74 years.

The author states, "A study of the mortality rates per million for respiratory and non-respiratory tuberculosis and cancer from 1893 shows that apart from the disturbances due to the wars the sum of the mortality rates of the two diseases remains constant at 2,500 from the year 1910 onwards. It would appear that the mortality from respiratory tuberculosis has been replaced by that from non-respiratory cancer and that from non-respiratory tuberculosis by respiratory cancer".

Work on the relation of the atmospheric benzpyrene to smoking and lung cancer in Liverpool and nearby rural districts have shown that: "(1) rural death rate from lung cancer increases in proportion with the maximum number of cigarettes which have been smoked habitually per week, (2) Liverpool rates exceed the rural rates by about the same amount in each smoking category, (3) the urban/rural ratio between the death rates among non-smokers is about 9 to 1 and corresponds roughly with the ratio between the concentrations of 3 : 4-benzpyrene, some other polycyclic hydrocarbons and sulphur dioxide, found in the air of a Liverpool locality and the concentrations found in rural situations in Anglesey and Cheshire".

Stocks and Campbell's report just mentioned is a first-fruit of a major co-operative investigation into the environmental histories of patients dying of cancer of all sorts in North Wales and Liverpool. Data on 12,000 such patients and 19,000 controls are now available. Among other findings based on this series may be mentioned the following: (*a*) Cancer of the uterine cervix can be related better to early commencement of child-bearing than to numerous progeny. (*b*) Cancer of the stomach, in rural Wales where it has a high incidence, appears to occur most often in those who have lived for long periods over soil of high organic content. (*c*) Those with a high intake of beer (but not of milk or tea, the former appearing actually protective) have a raised incidence of most forms of cancer (but not, oddly enough, of gastric cancer).

This kind of survey, which depends for its success on the co-operation of many separate agencies, is one for which the British Empire Cancer Campaign seems particularly fitted. Another activity one would like to see it promoting more vigorously is the investigation of the geographical incidence of cancer, a subject on which even in its simplest aspects a remarkable amount of work remains to be done. There are accounts of only two activities of this type in this year's report. From Hong Kong come reports of investigations of two tumours of importance in that area. Hou describes the post-mortem appearances of infestation with *Clonorchis sinensis*, which he believes to be responsible for 15 per cent of liver cancers in the area. Teoh describes the nasopharyngeal tumours of Chinese, and comes to a firm conclusion that they are squamous carcinomata. In both of these, experimental investigations are under way; in the latter the possibility that incense smoke is the cause is being examined.

In Uganda a Cancer Registry has been set up, and has had the benefit of a visiting statistician. It is hoped to produce reliable statistics at least for one large district around Kampala. So far it has not gone beyond indicating that the true total incidence of cancer in the African is probably not very different from that seen in Europe. It has been possible to confirm roughly beliefs that cancer of the penis liver, skin (especially Kaposi sarcoma) and uterine cervix are especially common, cancer of the respiratory and alimentary systems and breast relatively rare, and cancer of the testis, tonsil and thyroid apparently absent. Fuller reports from this Registry will be awaited with interest. One piece of work given little space in this Report, which could be a key to the incidence of liver cancer in the tropics is the *Senecio* alkaloid studies of Schoental and Head.

The Great Ormond Street review of the tumours of childhood continues. This year's instalment is prefaced by some observations on the way in which improved treatment of other diseases is increasing the importance of tumours as a cause of death in early life. Though only 1 per cent of admissions to the hospital are for tumours, they are the cause of death of 17 per cent of cases coming to post-mortem a figure second only to congenital malformations. Of the tumours nearly a third are intracranial, which are dealt with in some detail this year. The 203 tumours seen in this situation include 174 (86 per cent) glial and 29 (14 per cent) non-glial—the latter consisting of eighteen meningiomata, six craniopharyngiomata, four choroid plexus tumours and one ependymoma. Bodian classifies the glial tumours into (differentiating) medulloblastoma (70 cases), nodular astrocytoma (59), diffuse astrocytoma (25) and subependymal glioma (20). (It may be noted that this makes medulloblastoma the fourth commonest tumour of childhood, or fifth if one includes leukæmia: neuroblastoma, Wilm's tumour and lymphoma stand above it.) Medulloblastoma and diffuse astrocytoma appear to be nearly always fatal. In the case of nodular astrocytoma, subtentorial meningioma and subependymal glioma, the prognosis is more encouraging and the results of treatment appear to be improving.

Further details of the study of the effect of treatment of neuroblastoma with vitamin B_{12} in massive dosage are given. Though only moderately encouraging, with 25 per cent of two-year cures, the genuineness of the effect would appear to be established.

In an experiment on the effect of environmental factors on cancer incidence, fowls were kept in a climatic chamber at constant temperature and humidity, while their siblings were exposed to the ordinary vagaries of climate; the diet was the same in both groups. The result of constant climatic condition was to increase greatly the incidence of cancer, for in the climatic chamber thirteen of nineteen fowls died and were found to have been suffering from adenocarcinoma of the ovary, oviduct, mesentary, alimentary tract, spleen, or liver. During the same period, only one death occurred in the control group (variable climate) and no cancer could be found at post-mortem. The fowls in the constant climate chamber were sexually inactive (that is, ceased egg-laying) for an average of 1·5 months in the three years of the experiment, while the control (variable climate) hens ceased egg-laying for eight months. These experiments suggest that a constant environmental temperature and humidity has a powerful effect on the reproductive cycle, and that in the fowl, cancer of the reproductive system and also of the alimentary tract, the liver and the spleen is facilitated by environmental factors via the endocrine organs.

Electron-microscope studies of the virus-induced Rous sarcoma in the fowl has made possible the first definite morphological identification of this virus. It has been shown to have a diameter of 70 mμ, but is not constantly detectable in all filterable Rous sarcomas. Obviously there are some interesting gaps in our knowledge of this tumour awaiting elucidation. From eight different Rous tumours, the 70-mμ particles were detected in four, and their occurrence varied from one particle-bearing cell in 2,000 cells to one in 50 cells. When the cells of the tumour were disintegrated mechanically so as to liberate the virus, it was found that there was a very close correlation between the sarcoma-producing activity of the tumour of origin and the percentage of cells which contained the 70-mμ particles.

The investigation of the carcinogenic action of cholesterol is continuing; recent reports from the United States have claimed that some oxidation derivatives of cholesterol have a much more powerful carcinogenic potency than the parent sterol. Fieser, Bischoff and collaborators state that solutions in sesame oil of lathosterol, 6-hydroxy-Δ^4-cholestene-3-one and particularly 6-β-hydroperoxy-Δ^4-cholestene-3-one all produce sarcoma in 30–60 per cent of injected mice.

An interesting example of species differences in sensitiveness to carcinogens has been demonstrated in the reaction of the tissues of the rat and of the guinea pig to 2-acetamidofluorene. The rat develops malignant tumours of the liver, kidney, ureter, bladder, pancreas, acoustic duct, mammary gland, uterus and skin; but feeding the compound to guinea pigs for as long as four years produced no tumours of any kind.

Interesting facts have been discovered in a study of the behaviour of normal and of malignant fibroblasts when these are grown in tissue culture. When the pseudopodia of normal fibroblasts touch each other, adhesions occur and movement ceases. On the contrary, when the pseudopodia of malignant fibroblasts touch, no permanent adhesion takes place; the cell surfaces slide over each other.

Berenblum's early work on co-carcinogens (now termed 'promotors') dealt chiefly with the polycyclic hydrocarbons, for example, benzpyrene or 1 : 2 : 5 : 6-dibenzanthracene, as 'initiators' which were applied in sub-threshold doses to mouse skin and then followed up by promotors, the most effective being croton oil, which behaves like a photographic developer in making visible the preliminary effect of the initiator.

This work has now been extended by other investigators to show that the entirely different compound urethane is a potent initiator for mouse skin and that croton oil is an initiator as well as a promotor. New initiators have been found; for example, one of the most effective is allyl methane sulphonate and also β-propiolactone; furthermore, applied in sub-ulcerative doses, the lactone is a complete carcinogen and produces papilloma and carcinoma. The detergent 'Tween 60' has been found to have promoting activity. The problem of relating chemical structure with carcinogenic potency thus becomes more complex as carcinogens (whether the compound is a complete carcinogen or is only a promotor or an initiator) of widely different structure become known.

Tobacco tar has been tested for co-carcinogenic activity and with positive results. Mouse skin pre-treated (initiation) with benzpyrene developed papillomas when afterwards painted with tobacco tar, showing that the tar had a promoting effect.

In the ever-widening range covered to-day in research into the causes and treatment of cancer, the boundaries of the different fields of work become less distinct, and the physicist works in increasingly closer co-operation with his medical and chemical colleagues. Although the particular sphere of any one worker tends to become narrower, yet he is quick to make the most of the very varied tools available to him. This is well illustrated at one centre by the use of electron microscopy and autoradiography in the study of ultra-thin slices of tissues which contain carbon-14 or sulphur-35. A 1,000-curie cobalt-60 unit for the joint use of chemists, physicists and radiotherapists forms common ground for radiobiological research in another laboratory, and leads to the mutual discussion of other problems which are common to workers attacking the same basic problems from such widely differing approaches.

A considerable number of centres are installing, or have installed, sources of radiation of increasing penetration. Reports from various regions give details of measurements of the depth–dose distributions with 4–15 MeV. linear accelerators, and with cobalt-60 sources. The effects of the inhomogeneity of body tissues on the dose received in the various tumour sites, and also the relative biological effect of the various qualities of radiations used in radiotherapeutic practice are being investigated.

Methods of calorimetric dosimetry are being perfected to enable an accurate measure of beams of high intensity but short duration, such as are met with when using the linear accelerator. Scintillation dosimetric techniques can now be applied with an energy response constant to ± 10 per cent over the range 20 keV. to 2 MeV.

At the other end of the activity scale, equipment has been constructed for the continuous monitoring of the natural radioactivity of the atmosphere, and regular measurements are being made of the radon content of the air in both hemispheres. Measurements have also been made of the natural radioactivity of different types of building materials from different parts of the world, and calculations carried out on the doses received at the gonads for both males and females. With the increasing development of radioactive materials, arising from a variety of uses from the luminescence of wrist-watches to the 'fall out' resulting from atomic explosions, the radiation dosage-level of the population as a whole becomes of increasing importance. This is confirmed in this report by the increasing use of radioactive isotopes, not as therapeutic agents, but as diagnostic and research tools, for labelling red blood cells with iron-59, for radiography with thulium-170 and xenon-133, and for diagnostic tests for thyrotoxicosis using iodine-131, to mention but a few of the numerous routine uses.

SCIENCE BY THE UPPER FORM

A SESSION of Section X (Assembly of Corresponding Societies) of the British Association meeting at Sheffield was devoted to a series of papers by sixth-form pupils under the title "Science by the Upper Form". Its object was two-fold : to introduce the young people to the meetings of the Association and to give adult listeners an insight into the work and interests of potential scientists.

The session was popular and attracted the largest audience that the Section enjoyed. The papers covered a wide range, from a consideration of the teaching of the history of science in schools to the mating customs of bullfinches, and from a school astronomical project to observations upon animal life in a stream. They were all indicative of much careful thought, and, where the subject demanded it, close and continuous observation combined with accuracy in recording. The young people were to be congratulated on their timing. None exceeded the limit imposed and some ended with a few minutes in hand.

The session was opened by Anthony E. Hanwell (King Edward VII School, Sheffield), who, under the title "The Value of the History of Science in a Sixth-form Science Course", gave an account of a course involving two periods a week for two years. The course began with the early attempts of man to exploit and adapt himself to his environment, all of which were characterized by the lack of a desire to seek theoretical explanations of the processes used. This was followed by attention to the study of Nature by the early Greek philosophers; to the Roman attitude to such matters; to the general decline in learning in the Dark Ages, and the impact upon European thought and life of the rise of Arabic nationalism and the recovery of the ancient Greek writings.

The course dealt fully with the lives of Copernicus, Tycho Brahe and Kepler, and the far-reaching effects of the work of Newton. Other sections were concerned with the histories of magnetism, electricity and light, to which a considerable amount of time was given; but it was surprising to learn that the history of biology was dealt with only in outline, and that of geology apparently not at all.

The speaker said that he was impressed by the way in which the study of the experiments of the pioneers emphasized the necessity for accurate observation. This in ordinary class-room work seemed directed mainly toward "obtaining a more accurate answer to a particular experiment, when if the answer were known it is usually possible to surreptitiously modify the observations". He appreciated the necessity for dealing with failures as well as with successes, and concluded that "a history of science course can do much to rectify the errors of undue specialization" by providing the scientist with a broader knowledge of his subject, its aims, its limitations, and its possibilities for good.

In a paper entitled "British Finches", Kenneth R. Hughes, of Chesterfield, gave the results of observations on three of the common species that he had kept under observation. The behaviour of some kept under aviary conditions was found to be identical with that of the wild birds. From accounts of mating displays, nest-making and brood-rearing it appeared that the courting of bullfinches began in mid-April and lasted for about a fortnight. Nest-building began soon after mating and when incubation commenced the cock was rarely seen near the nest, though he shared in the feeding of the young while the hen was sitting on her second clutch. When the birds of the second brood were able to feed themselves the whole family gathered and remained together until spring, changing their summer woodland habitat for gardens and allotments during autumn and winter. In March the flocks separated into pairs and the yearly cycle began again.

Hawfinches next received attention. The courtship was seen to be a vigorous affair in which the female seems almost to be driven to build a nest. The young are reared on insects, and it is only later that they become the enemies of fruit growers and gardeners.

The work is continuing, for Kenneth Hughes has seven other species under observation. He regards finches as suitable for his purpose on account of the ease with which they may be kept under conditions almost natural to them.

Miss Anne Bunting contributed a paper on "Some Little-known and Unpublished Aspects of the Life-History and Habits of *Periplaneta americana* (L.)". Having reared the large American cockroach for a number of years, she had come to the conclusion that the periods of incubation and of growth from incubation to final moult were shorter than is stated in text-books. She found that the incubation period lengthens as the temperature decreases, that below 50° F. no incubation takes place, and that oothecæ submitted to this low temperature do not incubate if later exposed to more favourable temperatures. This was suggested as a partial explanation of the failure of the species to become widely established in Great Britain. Miss Bunting is a pupil of Thorne Grammar School, near Doncaster.

Keith L. Watson (Charterhouse) described "The Charterhouse Astronomical Project", the chief object of which was to revive within the school an astronomical society, first conceived when an observatory was added to the science laboratories in 1907. A retired master, Mr. R. C. Sclater, set up an observatory in his garden and made it a practice to invite parties of boys to make use of his telescope at week-ends. Unfortunately, he soon died and the project collapsed, to be revived again about four years later, in 1936. The organizers decreed that only sixth-form boys could become members—a rule that has now been wisely abandoned on the grounds that in order to maintain continuity with a changing school-population it is necessary to encourage the younger boys to take part. The work had to be suspended when war broke out and the observatory was used as a fire-watching post.

The present project was commenced in 1953 through the influence of a physics master, Mr. Hayward, and has been encouraged and assisted by a local medical practitioner, Dr. Lyne-Pirkis. To use Keith Watson's own words, "on a clear evening we are at liberty to telephone him and he picks us up in his car and takes us to his observatory where we always spend a very pleasant and instructive evening".

The work planned for the society is determined by the equipment available. The mirror of its original 6¼-in. reflecting telescope has been damaged, and since they cannot afford to pay for it to be repaired professionally the members intend to grind a new mirror for themselves. They now have also a 3-in. Cooke refractor, which, being simpler to use, is more popular.

Some of the boys are mapping portions of the Moon's surface, paying special attention to regions on the edge of the disk that, being difficult to observe and in many cases not very interesting, tend to be neglected by most astronomers. The main task of the solar section has been to plot the course and cycles of sunspots.

The society has about fifty members, but as with most local societies only a few are really active, the others being what Keith Watson aptly described as satellites, attending lectures but doing little practical work. It is interesting to record that a paper embodying observations on "Bee-eaters in Britain" was read by another Charterhouse boy, James J. Swift, at another session of the Section.

The last paper was on "The Ecology of Porter Brook", by John K. Chesters (High Storrs Grammar School, Sheffield). It was a description of work done on the headstream of the River Porter, which runs off the moors on the west side of Sheffield.

Animals were collected in a Surber net, the horizontal frame of which marked out one square foot of the bottom surface. The net faced upstream and collected all the animals loosened from the rocks and the bottom debris. The contents of the net were washed into jars and afterwards sorted, counted and identified.

A chart was prepared expressing the results of the count in terms of the distance in feet from the source of the brook and the months in which the samples were taken. This revealed interesting variations in the number and relative importance of several stonefly nymphs and chironomid larvæ in various parts of the brook and at various times of the year, and showed that annelid worms were found in large numbers near the source of the stream but not elsewhere.

As one of several examples of the results obtained, it was pointed out that the numbers of chironomid larvæ increased greatly (in April and May) at the junction of the Porter Brook with another small stream, the Mayfield. Since the larvæ live in the bottom organic debris and are liable to be swept away by fast bottom currents it was thought that their greater abundance in the combined stream was due to there being a relatively slower bottom current in the somewhat deeper water. Tests showed that on similar bottoms the bottom velocity above the junction was twice as great as below it.

The general conclusions arrived at were that the main factors affecting life in the stream during winter and early spring were the velocity and volume of the water, but that during the remainder of the year there were complications due to other factors such as the amount of vegetation overgrowing the stream and controlling not only the supply of higher plant material but also the intensity of illumination.

F. J. NORTH

OBITUARIES

Dr. G. J. H. Swoboda

GUSTAVE SWOBODA, who died at Geneva on September 4, aged sixty-three, was widely known to meteorologists as the administrative head of the pre-war International Meteorological Organization and its successor, the World Meteorological Organization. Swoboda was a Czech (he later acquired Swiss nationality), a native of Prague, where he graduated in 1920 with the degree of Ph.D. In the same year he joined the State Meteorological Institute and ultimately became chief of the forecasting service. During this period he lectured on meteorology at the technical college in Prague and wrote a technical treatise on aeronautical meteorology. He was one of the first meteorologists outside Norway to give whole-hearted support to the ideas of the Bjerknes school, and among other works he collaborated with T. Bergeron in a memorable essay on waves and vortices on a quasi-stationary surface.

The turning point in Swoboda's career came when he was appointed a member of the International Meteorological Organization's Commissions for Synoptic Weather Information and for Aeronautical Meteorology. The International Meteorological Organization was a non-governmental body, supervized by a conference of directors of various national services. Swoboda had, apart from his meteorological knowledge, one great asset for such international work. He was a very accomplished linguist, who spoke Czech and German as mother tongues, English and French with complete ease and had considerable knowledge of Dutch and several other European languages. It was therefore no surprise that in 1938 he was selected to succeed Dr. Cannegieter as chief of the secretariat of the Organization, and it was he who supervized the transfer of its headquarters from De Bilt to Lausanne.

Swoboda managed to hold the Organization together during the years of the Second World War and gained his reward in 1951 when the World Meteorological Organization, a Specialized Agency of the United Nations and the successor to the International Organization, appointed him as its first secretary-general. This post he held until September 1953 when he reached the normal age of retirement; but he continued to serve in an acting capacity until August 1955. At the time of his death he was professor of meteorology at Istanbul.

Swoboda's work as a scientist was recognized in 1953 when the Royal Netherlands Academy of Sciences awarded him the Buys Ballot Medal; but his unique contribution to meteorology undoubtedly was in the field of international co-operation. He was, in many ways, the ideal international Civil servant, and his success in this role arose as much from his kindliness and tact as from his linguistic gifts and administrative ability. He had not only a wide knowledge of his subject but also a great charm of manner and a genuine concern for the happiness and welfare of all around him. He leaves a widow and one son.

O. G. SUTTON

Dr. C. B. Rees

COLIN BEVAN REES died on September 2, a victim of cancer, at the early age of forty-one; and by his death marine biology has lost an enthusiastic and original plankton worker who was developing important new lines of research. Born at Pontardawe in Glamorgan on October 25, 1914, he was educated at Pontardawe Grammar School and University College, Cardiff. After graduating with first-class honours and making an ecological study of the fauna of the Severn Estuary, he was appointed in 1937 to the research staff of the Department of Zoology and Oceanography at University College, Hull, which was then expanding its plankton recorder survey. Jointly with Mr. K. M. Rae, he produced a report on the distribution of the Copepoda which was noteworthy for its account of the month-by-month advance of Atlantic indicator species into the North Sea from the north.

After war service as a captain in R.E.M.E., he returned to the plankton recorder team and moved with them to the new Oceanographic Laboratory of the Scottish Marine Biological Association at Edinburgh. He now conclusively demonstrated the reality of the previously disputed two forms of *Calanus*: *finmarchicus* and *helgolandicus*, and studied their distribution and development in different areas of the North Sea. Next he turned his attention to the planktonic larvæ of bottom-living invertebrates. He first set out to devise a method of identification for the multitude of lamellibranch larvæ; by using shape, form of hinge, and texture he distinguished seventy-seven types and produced an account, illustrated with diagrams and photographic plates, which has proved invaluable for other workers. A series of reports followed on the distribution of the larvæ of lamellibranchs, decapod crustaceans, echinoderms and other benthic animals. His University awarded him the D.Sc. in 1951. During his illness he made the final corrections to a further study of the two forms of *Calanus*, this time comparing their population production in the Atlantic and the North Sea over different seasons. He leaves a mass of data on the other copepod species which it is hoped may be prepared for publication later.

Colin Rees will be remembered by his colleagues and many friends for his devotion to research and for his cheerful good company. He was artistic and, as a hobby, painted in water-colour with distinction, exhibiting in leading Scottish galleries. Our sympathy goes to his widow and two children.

A. C. HARDY

NEWS and VIEWS

Brazilian Society for the Progress of Science

THE annual meeting of the Brazilian Society for the Progress of Science was held this year during July 2–7 in the old gold-mining centre of Ouro Preto. The president of the Society, whose term of office runs for two years, is Dr. Anisio Teixeira, the distinguished Brazilian educationist, and the inaugural lecture was given by Prof. Carlos Chagas, the president for the meeting, on "Prospects and Problems of Scientific Research in Brazil". The subjects discussed at the meeting, which was attended by about two hundred Brazilian scientists, were divided into nineteen sections. The largest number of papers were presented in the four sections devoted to physiology (including biophysics, biochemistry and pharmacology); physics (and astronomy); microbiology (including epidemiology and preventive medicine); and chemistry. Papers on biological and medical subjects accounted for 65 per cent of the total of 211 papers presented. Foreign guests included Prof. A. M. Monnier, neuro-physiologist, Prof. J. L'Héritier, geneticist, both of the Collège de France, Prof. J. A. D. Cooper, biophysicist, of the University of Chicago, and Mr. F. M. Beatty, science officer of the British Council in Brazil, who lectured on the training of scientists and technologists in British universities. The next annual meeting of the Society will be held in Rio de Janeiro during July 1957; the 1958 meeting, celebrating the first decade of the Society's existence, will be more international and will probably be held in São Paulo.

Electronic Equipment working at Red Heat

A DEMONSTRATION has recently been given at the Research Laboratory of the General Electric Company, Schenectady, N.Y., of electronic components and devices working at temperatures of red heat and, in some cases, under the action of intense nuclear radiation in an atomic reactor. Conventional electronic equipment usually breaks down at 200° F. or above (about 100° C.), although with the advent of guided missiles and supersonic aircraft a number of components have been developed capable of operation at 500°–600° F. (about 300° C.). If high-speed flight is to make considerable advances in the future, bulky power-consuming equipment for cooling will have to be eliminated, and components must be capable of working at very much higher temperatures. By suitable choice of such metals as titanium and special ceramics, General Electric has developed—so far only at the laboratory-level—electronic components that function at temperatures up to 1,500° F. (about 800° C.) and also at a high temperature in the neutron flux of the graphite reactor of the Oak Ridge National Laboratory. Among the equipment shown at the demonstration were a radiogram and valve amplifier operating in an oven at 1,500° F., and an electric motor in the flame of a blow-lamp. In some respects, the new 'heaterless' valves are an improvement on the more conventional pattern in that the power supply normally required for heating the filament is eliminated, and it is thought that this new type of valve, if operating under constant high-temperature conditions, may have a superior performance.

The French Atomic Energy Programme

ISSUE No. 16 of *Laboratoires*, the quarterly review in French and English of French scientific and technical developments, is devoted to the French atomic energy programme, and in particular, to the peaceful applications of atomic energy and to France's participation in the International Conference on the Peaceful Uses of Atomic Energy held in Geneva last year. J. Guéron, director of the French Atomic Energy Commission, contributes a brief foreword in which he stresses the rapid expansion of the French atomic energy programme since the adoption in 1952 of a five-year plan for atomic equipment. Prof. Y. Rocard reports briefly on the Geneva conference and the associated industrial exhibition, and Prof. P. Auger follows with a most interesting article on the training of research workers in the field of atomic energy, in which he maintains that care should be taken to avoid the introduction of specialization directed towards the new fields of science and technology at too early a stage. It will be necessary to modify the university curriculum so that student engineers and scientists are made familiar with the new domains of physics, chemistry and biology which are now assuming major importance; but the practical aspects of particular applications should not be given excessive importance. They should form part of a training programme to be given later at specialized centres probably attached to the larger establishments where the technique is being employed. Future research workers and engineers should be encouraged to extend their basic knowledge to fields outside their own professional spheres; for example, the chemist to radioactivity, and the mathematician to nuclear physics. In addition, Prof. Auger emphasizes the importance to the atomic scientist and engineer of ancillary services, the provision of an adequate number of trained technical assistants, a good information service and library, and the time and facilities to attend scientific meetings and conferences and for visits to other research establishments. Other articles in the issue are on automatic instruments for recording radioactivity, by Prof. P. Bonet-Maury, and on analogue computor simulation of the kinetic performance of nuclear reactors, by J. Girerd. Finally, there is a detailed illustrated technical review of the various exhibits of French instruments and equipment displayed by the forty-six French firms which took part in the international exhibition at Geneva last August.

Studies of the Upper Atmosphere

ONE of the classic works of meteorology is W. H. Dines's discovery (M.O. Geophys. Mem. No. 13; 1919), using his balloon-sonde observations, of the positive correlation between temperature in the troposphere, pressure in the upper troposphere, and the height of the tropopause and the negative correlation between these quantities and temperature in the stratosphere. Thus low pressure in the upper troposphere goes with a cold troposphere and a low tropopause. This discovery was the death-blow to the convective theory of temperate-zone depressions, which required depressions to be relatively warm. Using recent radiosonde observations, J. K. Bannon and A. Gilchrist (*Quart. J. Roy. Met. Soc.*, 82, 58; 1956) have repeated and much extended Dines's work. Bannon and Gilchrist used radiosonde observations at Arctic Bay (North Canada, lat. 73° N.), Lerwick, Larkhill, Malta, Aden and some equatorial Pacific stations for heights up to the level where pressure is 60 mb. (about 63,000 ft.). They confirmed Dines's results for the Lerwick and Larkhill observations and found the same result for Malta in winter and Arctic Bay in summer and autumn. At Aden and the equatorial stations and at Malta in summer no correlation could be found, and at Arctic Bay in winter and spring the correlation was less marked than at the British stations. Malta in winter and Arctic Bay in summer and autumn have a similar meteorological regime of travelling depressions and anticyclones and changing types of air-mass to that of the British Isles throughout the year. In summer, however, Malta is mostly in the area of the subtropical anticyclone, and Arctic Bay in winter and spring is in the area of a fairly constant low-pressure area with little change of air-mass. The conclusion is that the Dines correlations are characteristic of travelling depressions and anticyclones with frequent changes of air-mass. Dines evaluated correlations between tropospheric temperatures and pressure up to 9 km. (30,000 ft.). Bannon and Gilchrist found the correlation decreased rapidly at greater heights, so that the influence of travelling depressions and anticyclones was only half at 60 mb. what it was at 150 mb. (about 45,000 ft.).

Photometry of Telescopes and Binoculars

THE booklet "Photometry of Telescopes and Binoculars", which is No. 14 in the series of "Notes on Applied Science" produced by the National Physical Laboratory, Teddington (pp. 18+2 plates. London: H.M.S.O., 1955; 2*s*. net), explains the objects and methods of some of the test work performed for industry by the Laboratory. The quality of a telescope is judged by its definition, that is, its power of producing a sharply defined image of a distant, often inaccessible, object; but this quality is extremely difficult to express quantitatively and is not dealt with in the booklet. However, closely connected with definition is the question of contrast. If there is little difference in contrast between an object and its surroundings and the contrast-rendering properties of the telescope are poor, the image may be undetected. Veiling glare is a measure of the light scattered or reflected in the instrument which, falling on the image, reduces its contrast. Light transmission, the percentage of light transmitted in the central portion of the field of view by the optical parts of the telescope, is obviously also of importance in assessing the general performance of the instrument, in addition to field brightness, which gives a measure of the falling-off in illumination towards the edges of the field of view. The booklet describes in some detail the apparatus developed and used at the Laboratory for making measurements of the axial light transmission, the veiling glare index and the field brightness of telescopes and binoculars. The apparatus for the last-named measurement is still in prototype form.

Guide to the British Museum (Natural History)

It is interesting to compare the general format of the publications of the British Museum (Natural History) issued at the present time with those of, say, twenty years ago. Then an austere approach to the subject in strictly traditional covers repelled all but the most ardent of students; but to-day the "Short Guide to the Exhibition Galleries of the Natural History Museum", now in its fourth edition (pp. 28; 1956; 1*s.* 6*d.*), is in an attractive coloured and original cover and invites even the least interested in museums to glance at the contents. Following a brief historical introduction, the "Guide" describes in outline contents of the Central Hall and its five bays. Attention is then directed to a set of cases introducing the five Departments of the Museum—Zoology, Entomology, Geology, Mineralogy and Botany. The reader is quickly led through the Departments, and the special features of each are described in a few—in some cases dramatic—words. The "Guide" includes a table giving the geological time-scale and some general information concerning the Museum and its main activities. This indeed is a booklet which can be used equally as a guide during a visit to the Museum and afterwards as a reminder of the objects seen.

The Gila Monster of North America

The Helodermatidae are marked off from other lizards by the possession of grooved teeth in the lower jaw and of poison glands. The most widely known species is the gila monster, about which a number of myths and tales have gathered. Charles M. Bogert and Rafael Martin del Campo have made an exhaustive investigation into the natural history and ecology of the family and produced an interesting memoir (*Bull. American Mus. Nat. Hist.*, 109, 238+20 plates; 1956; 4 dollars). It does not deal with the anatomy except for a brief reference to the lower jaw, the arrangement of the bones of which provide a specific differentiation. The authors recognize two distinct species, *Heloderma horridum* and *H. suspectum*, which are distinguishable by definite external characters and have different distributions. *H. horridum* with three subspecies, each occupying its own area, is found on the Pacific drainage of Mexico, and it is suggested that it should be called the beaded lizard from the characteristic appearance of the skin: it is known in Mexico as the escorpión. It was first mentioned by Hernández in 1615. The other and better-known form is the gila monster, *H. suspectum* with two subspecies, found from just inside Mexico northwards into central Arizona. It has been shown experimentally that heloderms secrete a poison that is quite lethal to a wide range of animals including the common laboratory types. The authors have traced thirty-four recorded cases of gila monsters having bitten human beings, and in eight of these death was stated to have followed; but the actual records are not satisfactory, and in some there were contributory factors. The possibility cannot be ruled out, but the poison mechanism is not efficient, and it is probable that only in exceptional conditions could sufficient poison be injected to prove fatal. In the chapter dealing with myths there is an amusing tilt at the ardent systematist in the setting up of a genus *Sampoderma* for a creature described by a Mr. Holmes and a Dr. Watson from a locality near Baker Street.

Overseas Students at British University Institutions

Appendix III of the 1956 "Yearbook of the Universities of the Commonwealth" gives the number of overseas students enrolled for full-time study or research in British universities and university colleges at the beginning of the academic year 1954–55 as 9,050, of whom 1,261 were women, compared with 8,619 in 1953–54 and 6,264 in 1938–39. Of these, 5,575 came from other parts of the British Commonwealth, including 346 from Australia, 372 from Canada, 238 from the Gold Coast, 1,229 from India, 173 from New Zealand, 700 from Nigeria, 319 from Pakistan, 193 from Malaya (with 60 more from Singapore) and 491 from South Africa. Arts claimed 3,741 students, technology 1,799, medicine 1,597, pure science 1,316, dentistry 311, agriculture and forestry 214, and veterinary science 72. Excluding external students, London had 3,454 overseas students, Cambridge 820, Oxford 855, Edinburgh 683; but of the rest only Durham (356), Leeds (348), Manchester (393) and Glasgow (313) had more than three hundred. Outside the Commonwealth, the United States provided 820 students, and Egypt 306.

Guide to the Manchester Libraries

The North-Western Group of the Reference and Special Libraries Section of the Library Association has published, under the title "The Libraries of Greater Manchester" (pp. 92; 1956; 15*s.*), a guide to the resources and special collections of the region which both shows the wealth of recorded information available in the area and also the appropriateness of Manchester on this count alone as a regional centre if the Government ever attempts to develop a national library system, at least for science and technology. As Mr. L. L. Ardern, chairman of the North-Western Group, explains in an introduction, the guide is based on the 141 returns received to a questionnaire which was sent to all likely societies. Mr. Harold Smith's editing has provided a work which is both clear and concise and should enable the student or expert seeking information to decide readily which of the many libraries of the area is most likely to be able to help him; at the same time, it should minimize the chance of a library being troubled with a request which it is unable to meet by reason of its holdings and scope or on constitutional grounds. The guide is well produced and should materially assist in library co-operation and the more effective use of regional resources.

The Night Sky in October

New moon occurs on Oct. 4d. 04h. 24m., U.T., and full moon on Oct. 19d. 17h. 24m. The following conjunctions with the Moon take place: Oct. 1d. 02h., Venus 5° N.; Oct. 2d. 18h., Jupiter 6° N.;

Oct. 7d. 20h., Saturn 2° N.; Oct. 16d. 15h., Mars 9° S.; Oct. 30d. 11h., Jupiter 6° N.; Oct. 30d. 21h., Venus 6° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Regulus on Oct. 5d. 14h., Venus being 0·4° S., Venus with Jupiter on Oct. 25d. 14h., Venus being 0·2° N., and Mercury with Spica on Oct. 26d. 09h., Mercury being 4° N. Mercury can be seen before sunrise during the middle of the month, rising at 4h. 45m. on October 15. Venus rises at 2h. 0m., 2h. 30m. and 3h. 15m. on October 1, 15 and 31, respectively, and is very bright, its stellar magnitude being about −3·7; its distance from the Earth is increasing throughout the month, from 87 to 106 million miles, and the visible fraction of the apparent disk also increases, from 0·65 to 0·75. Mars rises at 17h. 20m., 16h. 15m. and 15h. 05m. on October 1, 15 and 31, respectively, and sets at 3h. 30m., 2h. 35m. and 1h. 50m. on the following mornings; its stellar magnitude decreases during the month from −2·2 to −1·3. Mars was at minimum distance from the Earth during September and is now getting farther away, being at 53 million miles by October 31; it is near ψ Aquarii throughout the month. Jupiter rises at 4h. 05m., 3h. 30m. and 2h. 45m. at the beginning, middle and end of the month, respectively; at the beginning of the month it is near σ Leonis and moves into Virgo, being near β Virginis at the end of the month. Saturn sets at 19h. 30m. on October 1, and is too close to the Sun for satisfactory observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Oct. 14d. 20h. 28·3m., c^1 Cap. (*D*); Oct. 22d. 23h. 05·4m., 129 H^1 Tau (*R*); Oct. 27d. 03h. 27·6m., A^1 Cnc. (*R*); *R* and *D* refer to reappearance and disappearance, respectively. The Orionid meteors are active during October 15–25, but conditions are unfavourable; the radiant is near R.A. 6h. 24m., Dec. 15° N. Taurid meteors may be seen during the last few days of the month; conditions are favourable and the radiant is near R.A. 3h. 36m., Dec. 14° N.

Announcements

The Messel Medal for 1956 of the Society of Chemical Industry has been awarded to Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd. The Medal will be presented to Sir Alexander at a special meeting of the Society on October 12 at 6.30 p.m., held in the Royal Institution, Albemarle Street, London, W.1, when he will deliver an address on "The Chemical Industry: Some Achievements; Some Problems".

Mr. L. A. Wiseman, who is at present working at the Atomic Weapons Research Establishment at Aldermaston, has been appointed deputy director of the British Rayon Research Association.

The following appointments have been made in the Department of Chemistry of the University of British Columbia, Vancouver: Dr. J. Halpern, associate professor; Dr. H. G. Heal, assistant professor; and Dr. G. Porter, instructor.

Six transfer scholarships provided by Imperial Chemical Industries, Ltd., have recently been awarded to sixth-form boys for study at the University of Liverpool. The scholarships are specially designed for those who have specialized in arts subjects at school but who wish to pursue scientific studies at a university, and they cover a one-year course of intensive preliminary training in the basic sciences as a preparation to study for a degree in science (see *Nature*, March 31, p. 606). In general, the scholarships are tenable at the Imperial College of Science and Technology, London, King's College, Newcastle upon Tyne, and the Universities of Cambridge, Liverpool and Oxford.

The Chemical Society invites applications for the Corday–Morgan Medal and Prize for 1955, for work in experimental chemistry, published in that year, by a British person who at the time of publication was less than thirty-six years old. The award consists of a silver medal and prize of 200 guineas. Details of the application, to be made by December 31, and further information can be obtained from the General Secretary of the Society at Burlington House, London, W.1.

A Harrison Memorial Prize, not exceeding 100 guineas, is being offered this year for chemical research over the past five years by a natural-born British subject not more than thirty years old. The selection will be by a committee consisting of the Presidents of the Chemical Society, the Royal Institute of Chemistry, the Society of Chemical Industry and the Pharmaceutical Society. Details of application, which must be made by December 1, and further information can be obtained from the President of the Chemical Society, Burlington House, Piccadilly, London, W.1.

The Royal Commission for the Exhibition of 1851 is increasing the value of its awards for scientific research, and as from October 1 the senior studentships for workers recommended by universities in Great Britain will be £800 a year and the overseas scholarships for students from universities of the British Commonwealth (and Eire) will be £550 a year; in each case, annual grants of up to £100 a year for approved fees and expenses will be available.

A congress on "Rockets and Guided Missiles for Continental Connexions and Telecommunications", together with an exhibition of rockets and guided missiles and their associated equipment, will be held in Paris during December 3–8 under the auspices of the Association pour l'Encouragement à la Recherche Aéronautique. The congress will be international in scope and will be broadly divided into two groups on scientific and technical studies and on economic studies, respectively. Further information can be obtained from A.E.R.A., 1 rue de Courty, Paris 7^e.

An international conference on "Operational Research", organized by the Operational Research Society (Great Britain), the Operations Research Society of America and the Institute of Management Sciences (United States), will be held in the University of Oxford during September 2–6, 1957. There will be four sessions on the common themes in operational research; methodology; and applications (two sessions). Those wishing to read papers should send summaries in duplicate, and not more than two hundred words in length, not later than November 30 to either Dr. Thornton Page, Operations Research Office, 7100 Connecticut Avenue, Chevy Chase, Maryland, or to Mr. B. H. P. Rivett, Operational Research Society, 2 Grosvenor Place, London, S.W.1.

Erratum.—In the article on "The 1956 Cambridge Summer School in Physical Chemistry", published in *Nature* of September 15, on p. 578, eleven lines from the bottom of column 1, for "carbon monoxide" read "chlorine monoxide".

MICROSCOPY WITH X-RAYS

SYMPOSIUM IN CAMBRIDGE

IN the sixty years since the discovery of X-rays, very wide use has been made of them in industrial and medical radiography. These macroscopic studies of internal structure have proved of value both in research and for purposes of non-destructive testing. Only comparatively recently, however, has attention turned to the value of X-rays for microscopic investigation, and real progress towards a resolving power of optical order has had to wait until the post-war decade. Refinement of the normal radiographic technique, by using photographic emulsions of high resolution, has been accompanied by the development of a point projection method and by the use of reflecting mirrors to form an instrument more nearly akin to an optical microscope. The very short wave-length of X-rays, compared with visible light, holds out the ultimate prospect of a greatly improved resolution; but a more immediate advantage lies in the ability to examine specimens that are opaque at the usual optical wave-lengths. With X-rays it is also possible to get good micrographs from much thicker sections of transparent materials than can be tolerated in the optical microscope, on account of its very small depth of focus at high magnification.

These prospective advantages, as well as interest in the physical principles involved, have stimulated an increasing interest in the use of X-rays for micro-structural investigation. To bring together those actively working in the subject, a symposium on X-ray microscopy and microradiography was held in the Cavendish Laboratory, Cambridge, during August 16–21. It was sponsored by the International Union of Pure and Applied Physics, and received financial support from the United Nations - Educational Scientific and Cultural Organization and from a number of industrial concerns in Britain. The response to its announcement was much greater than anticipated. In addition to those from the three main centres of activity, in Stanford University, California, the Caroline Institute, Stockholm, and the Cavendish Laboratory, participants came from nine other countries and papers, to be read in absence, from two others (Uruguay and the U.S.S.R.). In all, there were 125 members of the symposium and sixty-six papers were read.

The symposium was opened by Prof. N. F. Mott, as president of the International Union of Pure and Applied Physics and head of the Cavendish Laboratory. A general survey of the use of X-rays for microscopy by Dr. V. E. Cosslett (Cambridge) was followed by introductory accounts of the three chief methods: of the grazing-incidence reflexion technique by Prof. P. Kirkpatrick (Stanford), of contact microradiography by Prof. A. Engström (Stockholm) and of the projection method, using a point-focus tube, by Dr. W. C. Nixon (Cambridge). The following two days of the meeting were devoted to the problems of each technique in turn, including the special needs of micro-diffraction and of quantitative analysis by absorption, emission and fluorescence spectrometry.

Conditions of grazing incidence are new in optical theory. Considerable progress has been made at Stanford in the design of the form of aspheric surface best calculated to provide a practically useful compromise between width of field and resolving power. A four-mirror system computed by Dr. H. H. Pattee (Stanford) should give a resolution of 500 A. over a field of at least 20μ with X-rays of wave-length 4 A. However, to obtain this performance, the mirror contours must be true to within 50 A., and, to reduce scattering to a sufficiently small value, the surface must be molecularly smooth. The immediate problems therefore lie in the working and testing of mirrors and, once they have been made, in their precise alinement. New techniques were described for these purposes, as it is not enough simply to refine existing optical methods. An experimental microscope, reported by Dr. J. F. McGee (Stanford), incorporates two uncoated silica mirrors and two adjustable aperture stops. Using aluminium radiation (8 A.) a resolving power between 0·5 and 1μ has been obtained. In these systems the mirrors of an imaging pair are axially separated. M. Montel (Laboratoire de Chimie-Physique, Paris) has devised an elegant method of sectioning spherical mirrors and uniting two half-mirrors at the appropriate mutual angle, so as to eliminate astigmatism and anamorphism.

By contrast with reflexion microscopy, which is faced with severe technical problems, the contact method of microradiography is limited in performance only by the effective grain size of the photographic emulsion. The development of emulsions of resolving power 2,000 lines/mm. now permits microradiographs to be obtained with a resolution approaching that of the best optical microscope. Prof. Engström described his work with softer X-rays (200–2,000 V.) than those usually employed. X-ray pictures of chromosomes and other cell components were shown which had a resolution of 0·3–0·5μ. An X-ray tube specially developed for these wave-lengths was described by Prof. P. J. Fitzgerald (College of Medicine, State University of New York), and an adapted commercial tube by Dr. A. Recourt (Philips, Eindhoven). Dr. B. L. Henke (Pomona College, California) has developed a tube having a gas-discharge type of electron source and a reflecting mirror for X-rays of 10–100 A. wave-length, in order to obtain better intensity in a region where efficiency of X-ray production decreases rapidly.

The point projection type of X-ray microscope, using magnetic lenses to obtain an electron spot as small as 0·1μ, was discussed by Dr. W. C. Nixon (Cambridge), Dr. J. B. Le Poole and S. P. Ong (Technical University, Delft) and Prof. B. M. Siegel (Cornell University). A resolving power approaching that of ultra-violet microscopy has been obtained by Nixon, with an exposure time of about 1 min. Smaller electron spots, certainly down to 100 A., can be obtained, but only with rapidly decreasing X-ray output, since the final electron lens has to be stopped down because of high spherical aberration. The need to increase the intensity of the electron beam, in compensation, was discussed by several authors. Dr. B. M. Rovinsky (Institute of Machine Sciences, Moscow) described a tube with ring cathode and needle-point anode, and the converse system using a point cathode and field emission was discussed by Dr. Pattee and by Dr. L. Marton (National Bureau of Standards, Washington, D.C.). The former has obtained high emission, but only at very high vacuum; the latter has worked at the vacuum more usually prevailing in a demountable apparatus, obtaining so far only small beam currents. In view of the difficulty of obtaining stable field emission in such circumstances, it appears at present that the best prospect for increased intensity in the point-focus tube lies in correction of the spherical aberration of the magnetic lens. The projection method has the advantage of direct enlargement on normal emulsions, but at cost of small field of view; the contact method gives a large field, but has greater difficulties of specimen preparation (since the specimen has to be very thin and placed almost directly on the emulsion) and of photographic processing. Even if a grainless film of reasonable speed can be developed, the optical viewing system will impose a limit on resolution—unless the emulsion can be stripped and viewed in the electron microscope. A possible technique of this nature was described by Dr. W. A. Ladd (Ladd Research Industries, New York), in which the 'emulsion' is a plastic film in which X-rays produce solubility changes depending on amount of exposure.

Even though X-ray methods may equal and perhaps exceed the optical resolving power, their main value in biology is likely to lie in the ability to distinguish different elements in the specimen, by means of differential absorption, emission and fluorescence. A large number of contributions was devoted to these methods of quantitative analysis. The Stockholm school has investigated in detail the accuracy attainable in absorption spectrophotometry, utilizing the characteristic absorption edges of the different elements. Dr. B. Lindström reported on analysis of sulphur and phosphorus in biological material, using a new high-vacuum apparatus and soft X-rays, and Dr. G. Wallgren described his studies in the mineralization of developing bone in human embryos. By direct microphotometry, analyses can be carried out on areas of tissue down to $3\mu^2$; a scanning and computing instrument for this purpose was described by Dr. O. Hallen (University of Gothenburg).

The projection method can also be adapted to microanalysis, and is especially useful for areas smaller than a few square microns, since photometry or photon-counting is carried out directly on an enlarged image. Mr. P. Duncumb (Cambridge) dealt with the design and operation of a flying-spot system for the analysis of thin layers by X-ray emission: the characteristic lines are detected and their strength measured by a proportional counter. An accuracy approaching 1 per cent can be obtained with a spot 1μ in diameter, and neighbouring elements in the periodic table can be separated if a crystal spectrometer is used. Mr. J. V. P. Long (Cambridge) described the adaptation of a projection X-ray microscope for the analysis of selected regions of a specimen, under a stationary spot, by fluorescence, absorption or emission methods at will. In emission, the specimen can simultaneously be viewed in transmitted light by an optical microscope. The limits of microchemical analysis by these methods were discussed by Prof. A. V. Baez (Redlands University, California). A detection limit of 1 per cent in a volume of $1\mu^3$ is equivalent to a mass sensitivity of 10^{-14} gm. of substance of unit density. At the moment, it is possible to determine elements of medium atomic number, down to aluminium or perhaps magnesium. Prof. Engström and Dr. Henke discussed the practicability of analysing separately the carbon, oxygen and nitrogen content of biological tissues with very soft X-rays, and it appears that this may be done with an accuracy of 5–10 per cent. Such a technique will be of revolutionary value in cytochemistry, just as the qualitative results obtained with microradiography are creating a new subject of microanatomy.

The sessions on applications of X-rays to microscopy, at the moment primarily using the contact method, covered a very wide range of subjects at the symposium. In biology, reports were presented of work on plant cancers and the growth of inorganic crystals in leaves, on the progress of osmium fixation in tissues, on the microstructure of wood and on insect flight musculature. In the medical field, investigations were reported of cancer of the breast and of the cervix, the human eye, the vascular patterns of human muscle and skin, growth of stone in the kidney and the embryonic stages of dentition. New techniques are now making it possible, particularly with the projection method, to observe changes in living tissue under experimental treatment. The metallurgical session was shorter, but contained accounts of the use of microradiography in studying segregation effects in ferrous metals and in light alloys, especially of aluminium, and the growth of oxide films. Preliminary studies of the distribution of heavy elements in rock sections were also reported.

Some discussion took place, formally and informally, on the need for further meetings on the subject of X-ray microscopy, for a specialized abstracting service and for clearing up matters of terminology. A small committee was set up to look into possible forms of organization, with particular regard to existing bodies and the need for connexion with the International Council of Scientific Unions. Its report will be prepared in time for discussion at the next symposium, which it is hoped to hold in Stockholm in 1959. V. E. Cosslett

THE EIGHTEENTH INTERNATIONAL GEOGRAPHICAL CONGRESS

THE eighteenth International Geographical Congress was held in Rio de Janeiro during August 9–18. The 1,006 delegates actually present included nearly four hundred from overseas, representing more than forty countries. The first congress was in 1871, yet this was the first to be held in the southern hemisphere, the first in the Tropics and the first in Latin America. It was opened in a blaze of pageantry by the President of Brazil in person at the Municipal Opera House. The delegates were welcomed by the President of the Organizing Committee of the Brazilian National Committee for Geography, and the British President of the International Geographical Union (Prof. L. Dudley Stamp, elected at Washington in 1952) gave a précis of his presidential address on the "Measurement of Land Resources". In order to secure some more precise measure of the capability of different types of land in differing climates and under differing types of management to support human life, he suggested the introduction of a 'Standard Nutrition Unit' of 1,000,000 calories annual production or 900,000 calories of net annual consumption. It was shown that a varied diet based largely on meat may require 3½ acres or more to produce one such unit, whereas with an extreme concentration on high-calorie foods (for example, rice and sweet potatoes) and intensive multiple cropping, as many as 6½ units per acre are produced in Japan, or more than twenty times as much.

At the first session of the General Assembly, four countries were elected to full membership—the U.S.S.R. (which had sent a strong delegation), Iceland, Hungary and Ethiopia. This was the first participation of the Russians since before the Second World War. With the object of helping the development of geographical research in countries with an insufficient number to set up the National Committee required of adhering nations, the General Assembly added to the Statutes provision for a class of Associate Members and elected as such the Sudan, French West Africa, Nigeria, Uganda, Kenya and Iraq.

More than three hundred papers, printed in abstract in advance, were presented to the dozen working sections into which the Congress was organized. Much attention was also given to the presentation and discussion of commission reports. At each Congress, the General Assembly, with the guidance of the Executive Committee, appoints commissions, consisting of not more than six full members, to carry out investigations into specific problems. Each commission must present a report at the next Congress, but may be reappointed for a further term. Reports presented were those on Medical Geography (which also had an active and flourishing section dealing both with the geographical distribution of disease and relevant factors), Evolution of Slopes, Erosion Surfaces around the Atlantic, Coastal Sedimentation, Periglacial Phenomena, Karst Phenomena, Arid Zones, the Library Classification of Geographical Books and Maps, An Inventory of World Land Use (a record of work known to be in progress in different countries) and The Teaching of Geography in Schools (a factual survey). Published reports, printed or mimeographed, on all these subjects were presented; an interim note was received from the Commission for the Bibliography of Ancient Maps. A Special Committee on Conversion Tables presented a report recommending what tables should be prepared and published. Some of the reports have been published as special parts of scientific journals; of most a small number is retained for distribution by the secretariat. An immense amount of valuable work is in progress and, despite extremely limited funds, the General Assembly agreed at its final session to the reappointment of all these commissions. In addition, the Executive Committee has set up two official commissions: one on the Mapping of Population, and the other on the Humid Tropics, to collaborate with other organizations working in these fields. Two new commissions were also approved: on National Atlases and on Applied Geomorphology.

The arrangements for the conference were excellent. The Brazilian Government made generous financial provisions which enabled a number of distinguished foreign delegates to be offered free air passages. The Navy allowed the meetings to be held, and some two hundred delegates to live, in the well-equipped Escola Naval, delightfully situated in Rio harbour on an island, now almost linked with the heart of the city by the reclaimed land on which the City airport is situated. Many nations joined in providing a magnificent map exhibition housed in the new Ministry of Education building, which also provided an auditorium equipped with simultaneous translation facilities for plenary sessions. In another building was a large selection of Brazilian maps.

The field trips arranged before and after the Congress enabled a large number of delegates to appreciate some of the problems of a vast and difficult country larger than the United States. Travelling by motor-bus over the winding mountainous dirt roads made the reason why 40 per cent of travel is by air obvious: there were times during each day when delegates saw more than one plane a minute handled by the Rio City airport. The extreme contrast between such great skyscraper cities as Belo Horizonte—their very names scarcely known to foreigners—and the vast uninhabited scrub-lands and forests impressed itself on all, while the two three-million cities of Rio and São Paulo left the impression of a growth too rapid for local administration to catch up. Everywhere the delegates met the lavish hospitality and boundless enthusiasm of the Brazilians; but standing above all was the organizing genius of Prof. Hilgard O'Reilly Sternberg and his faithful band of volunteer helpers.

At the final session of the General Assembly the presidency of the Union was handed over to Dr. Hans W:son Ahlmann, of Sweden, distinguished glaciologist, diplomat and don, and the joint invitation of the five Nordic countries of Norway, Sweden, Denmark, Finland and Iceland for the Congress of 1960 was accepted. For the past seven years the secretariat of the Union has been in the able charge of Dr. G. H. T. Kimble as secretary-treasurer: it is now to be transferred to the University of Zurich under Prof. Hans Boesch. The new Executive comprises the President, Secretary-Treasurer and Prof. Sternberg as first Vice-President, together with six Vice-Presidents—Profs. Hassan Awad (Egypt), Chauncy Harris (United States), Max Sorre (France), L. Dudley Stamp (United Kingdom), Fumio Tadâ (Japan), and Carl Troll (Germany).

L. DUDLEY STAMP

SCIENCE AND STRATEGY

THE modern Totalitarian Government considers itself above all moral criticism, and pursues its aims by murder by the million, routine employment of torture, the use of deliberate lies, the perversion of justice and, above all, by treating formal agreements as stopgaps to be broken whenever any least advantage is to be gained. Into this world, where good faith has almost vanished from international relationships, there has arrived the control of nuclear energy, which at the same time holds out great hopes for the improvement of man's estate and permits the construction of weapons which stand in a more extreme ratio to those of the Second World War than the latter do to the weapons of the Stone Age.

The authors of the papers in a discussion published in the *Bulletin of Atomic Scientists* for May, while repeating again and again the urgency of a genuine peace, consider the functions of the Armed Services in a world where no such agreement has been reached. It is generally agreed that the H-bomb is a great deterrent; but the first contributor, Sir John Slessor, tries to see just exactly what it will deter. He concludes that global war in the 1914 or 1939 style is finished, since the object of governments is to win a war, and the new weapons imply such appalling destruction that no war can be won. But he points out that any ban on nuclear weapons alone would "obviously suit the Communists to engage in a war in which their enormous superiority in manpower and conventional armaments could hardly fail to be decisive". For the Western Powers to refuse ever to use the bomb first would ensure their defeat; any uncertainty about its use might lead to another "drift into war". He then puts forward some very interesting arguments that the function of conventional armaments in this situation is as a "trip-wire" to ensure that any future aggression cannot gain its ends without having to face full-scale nuclear war and that, since no future global war can possibly last long, economies must be looked for in those applications required only for long-term hostilities.

The second author, Dr. R. L. Meier, sets out a series of propositions which he considers valid where "there are no important constraints upon how the major powers may act in the short run". The most important and most controversial are No. III, in which he argues for a sharp distinction between conventional weapons and nuclear weapons (Sir John Slessor separates "tactical" nuclear weapons from the H-bomb), and No. VI, that when superweapons have reached a certain level "it appears to be no longer possible to negotiate disarmament at the nuclear level" because "any nation which does not act in good faith would be able to dictate terms to any part of the world, or annihilate it" since "the margin of error in detection and accounting is still enough to dominate". Back to good faith once more.

The third author, Mr. Hanson W. Baldwin, starts with an illuminating and balanced discussion of the new methods for delivering nuclear explosives, and points out that, while the power of the attack has so enormously increased the power of defence, interception has considerably decreased. He recommends that "we must be capable of fighting all-out nuclear war, a limited nuclear war, a major non-nuclear war, small scale brush-wars". This counsel of despair may perhaps be practicable for the United States with its immense resources; it could scarcely be so for Great Britain.

The fourth author, Mr. C. W. Sherwin, emphasizes a further point. That old-fashioned principle of war was to seek out and neutralize the armed forces of the enemy. But in a modern future war these armed forces will be small, light, mobile machines, which can be fairly easily protected against blast, while cities are large, immobile and from their construction very sensitive to blast. In other words, success is probably much easier by attacking civilian populations. This was once forbidden by a Geneva Convention; but such conventions again imply good faith. Mr. Sherwin proceeds by outlining a set of rules for nuclear strategy in a deterrent war; even supposing these rules to be correct it is most unlikely that they could be followed in the mass hysteria of an atomic war. He concludes by hoping that, while the Mark I solution of peace-through-deterrence is perhaps not the ultimate means of preventing major war, it may give time for a final solution. Dr. Warren Amster concludes the discussion in a short article which emphasizes the points made by the previous authors.

This discussion is of the utmost interest, and can scarcely be summarized in so short a review. The discussion is being continued. E. C. BAUGHAN

RESEARCH COUNCIL OF ALBERTA

REPORT FOR 1955

THE thirty-sixth annual report of the Research Council of Alberta*, covering 1955, refers to increased emphasis on basic geological research and survey in view of its importance to much of the Province's resources. Besides the oil-sand area project, clay research, glacial geological studies and micropalaeontological research carried over from 1954, further work undertaken included a ground-water survey of the Province, stratigraphical studies of the southern foothills, and a laboratory study on the chemical variation between marine and non-marine sediments. The Council's soil surveyors were again engaged principally in the Peace River district of Alberta; but the report refers also to other projects of the Alberta Soil Survey conducted mainly by Federal Survey staff, such as the field-work on the Edmonton map-sheet and irrigation research on solonetzic soils at Youngstown, in co-operation with the University of Alberta Department of Soil Science, the Canada Experimental Farms Service and the Provincial Department of Agriculture.

Encouraging progress has been made in the re-orientated coal research programme. Investigations of the physical behaviour of coal in an ultrasonic field demonstrated that the 'true' density of coal appears to remain substantially unaffected, but that the surface area of the coal tends to increase with the frequency of vibration and time of exposure; preliminary carbonization tests have indicated that the presence of traces of nitric oxide in the retort can induce significant modifications in the nature of the tar. A combination of infra-red studies and elementary analysis has indicated the relation between humic acid and coals of various ranks, and studies of the oxidation of phenols to humic acid have shown that oxidative polymerization of aromatic substances can yield naphthenic structures known to occur in coal and petroleum. Polarographic studies indicate that humic acids from hydroquinone and low-rank coal have less condensed structures than humic acids from material of higher rank. The presence of a cracking catalyst such as alumina-silicate in carbonization about 600° C. appeared to affect the primary decomposition of the coal as well as the secondary decomposition of the primary tar.

The work of the Applied Research Laboratory was confined to attempts to surface-seal Albertan sub-bituminous coals against loss of water so as to prevent or reduce disintegration during storage. Some success was achieved with emulsions of wax or bitumen, and substantial progress was also made in a study of the grindability of coal.

Petroleum research has included studies of the kinetics of thermal degradation or maturation for the removal of vanadium or nickel from McMurray oil; the work indicates that geological time has been too short to account for the observed maturation of crude oils in Alberta at the temperatures usually regarded as reasonable during geological time, and suggests that considerable importance must be attached to catalysis in the formation of crude oil. A survey has been undertaken of the carcinogenicity of crude oils of Western Canada; detailed investigations of the sulphur content of heavy oils using chromatography on the distillate fraction showed that extraction methods for removing sulphur from the oil-sands oil are unsatisfactory, and studies are being made of desulphurization by catalytic decomposition or oxidation.

---

* Research Council of Alberta. Thirty-sixth Annual Report, 1955. (Report No. 73.) Pp. 52. (Edmonton: Research Council of Alberta, 1956.)

Work on natural gas and its utilization was limited to three projects: the partial oxidation of *n*-butane; the production of carbon black; and the high-temperature pyrolysis of butane. Results in the first project indicate that the reaction is essentially that of the 'cold flame', characterized by a pronounced induction period, sharp reaction peak and self-quenching termination. Use of the permeable tube technique has permitted continuous production of carbon black from natural gas for up to four hours; but extensive semi-works tests are required before any economic evaluation of the process can be made. Preliminary results indicate higher partial pressures in the pyrolysis of butane favour formation of ethylene and lower pressures that of acetylene. Winter field trials of the injection of lignosol and lignosol–chromate mixtures to prevent frost-heaving in soils showed that the highly mechanized procedure was less efficient than anticipated and that the designed proportions of lignosol and chromate were not set up in the field as successfully as in the laboratory; a study of the electrosmosis of soils showed that addition of lignosol enabled the solution to move through coarse sands in which the process was ineffective in its absence.

The paucity of the cyclic animal populations continued throughout central and northern Alberta; but a careful census showed increases in selected locations, especially in the south-east of the Province. Measurements of solar ultra-violet radiation were continued. Work on the hatchability of turkey eggs demonstrated that the use of upstanding males in the breeding pens increased fertility compared with eggs from pens in which front-heavy males were used.

Some attention has been given by an *ad hoc* committee to the prevention of hail damage.

RELATIVITY AND SPACE TRAVEL

AFTER the publication in *Nature* of April 28 of communications on this subject by Prof. H. Dingle and Prof. W. H. McCrea, a number of letters were received by the Editors, some of them supporting Prof. Dingle's views and some Prof. McCrea's. Many were mathematical in character, whereas others developed the argument in general terms. It would have been impossible for reasons of space alone to print these letters in full; it seemed to the Editors, therefore, that the best course was to collect the correspondence and to submit a copy of each letter to Prof. Dingle and to Prof. McCrea, who were then invited to prepare their concluding statements in the light of the letters received. This has been done, and the two statements are published below.

THE outstanding fact confirmed by this correspondence (in which I include letters received privately) is profoundly disquieting. In various ways we now actually deal with velocities at which the abnormal relativity phenomena become important, and in matters the gravity of which can scarcely be exaggerated and in which we must act on calculation alone, we are at the mercy of physicists, many of whom can believe that what can be thought away can have effects which cannot.

For obvious reasons, I reply only to correspondents who agree in (and only in) thinking me wrong. They comprise two classes: (*a*) those who hold that the accelerations are irrelevant and I have misread 'special' relativity; (*b*) those who regard the accelerations as important. (McCrea so regards them, but bewilderingly uses them only as a talisman to fecundate the otherwise sterile 'Lorentz contraction' during the *uniform* motion.)

It is difficult to understand the existence of class (*a*), since without the accelerations M and R are indistinguishable. A number 'refute' me by the phenomenon of mesons, the half-life and velocity of which imply that they have suffered a 'time dilatation'. I am astonished that this is thought relevant. The argument seems to be this: "Dingle says that the relativity anomalies are only imaginary: this one is observed: hence Dingle is wrong". What I say is not that these anomalies are "only imaginary", but that they occur only when at least one of the times involved refers to an absent clock and so must be determined by a conventional definition. This is so in the meson case, where effectively the starting time (conventional) is compared with the arrival time (observed); the 'time dilatation' must therefore be expected. In the space traveller problem, however, the clocks are directly compared; convention is eliminated and the anomalies disappear.

In reply to requests, I reluctantly indicate McCrea's error. He writes: "At the event [E_1] of M's completing the part of his outward journey performed with speed V, observer R plots M as at a distance X. . . . Owing to the Lorentz contraction, M at the same event plots R as at distance αX. . . . It does not matter which observer regards himself as at rest". But M observes *another* event, E_2, at which R's uniform travel ends, and McCrea later confirms that it is at E_2 that R's distance is αX. Hence he connects R's estimate for one pair of events (E_0 and E_1, where E_0 is the event of R and M beginning their separation with velocity V) with M's for another (E_0 and E_2) by the "Lorentz contraction", which is clearly wrong. But I repeat that the error of the conclusion should be obvious without this.

A complete solution of the space traveller problem on the basis of special relativity, showing how the anomalies cancel out, will be published by the Physical Society.

Now for the accelerations. General relativity asserts that *all* motion is relative (that is, all coordinate systems are equivalent). It has convincingly formulated this principle only for gravitational motions; but, if it is true, no acceleration affects a clock. Some think this inconsistent with the displacement of spectrum lines in a gravitational field, but that is caused by the *field*, not acceleration. If the stellar atoms are stationary it is still required.

We do not know what effect other causes of acceleration may have. Hence, since our traveller will certainly not be ejected by gravitation, we cannot state the effect, if any, of the means employed. But, by hypothesis, the process is too brief for appreciable slowing down.

The only escape is by supposing, as some do, that the initial acceleration causes a change of rate which persists when the motion becomes uniform. This is arbitrary, and to justify McCrea's formula the change would astonishingly have to be exactly equal to the

Lorentz value for the final uniform motion for all methods and degrees of acceleration. Also, it would stultify modern astronomy, because every supposed Doppler effect might be actually the legacy of earlier unknown accelerations.

The only attempted defence of this is by an enormous generalization. The paths of the Earth and traveller are considered as world-lines in some specifiable space-time, and it is pointed out that such a space-time permits alternative world-lines with very different proper times. No doubt; but those who reason thus omit to specify the space-time and to show that the paths in our problem differ by the assigned amount, and I am certain that they cannot. The invocation of space-time is quite unnecessary, but if done it must be done thoroughly.

To sum up: if accelerations are ignored, symmetry shows that the clocks cannot differ on re-union. If, however, accelerations determine the issue, then either the 2½ years (if gained at all) is gained during them or they affect the later rate of the uniformly moving clock. The former is impossible; the accelerations may be far too brief. Hence the rate of a uniformly moving clock, for no known reason, depends on previous accelerations, and all astronomical deductions from supposed Doppler effects are vitiated.

A final word on the moral of the whole thing. I have been told by some who omit to give reasons for their views, that although I may not understand the matter, mathematicians do so very well and agree that I am wrong. I am not, and have no wish to be, a mathematician in the restricted sense; by nature and taste I choose the world of experience, and I trust reason rather than personal authority however graciously exercised. Nevertheless, "when the wind is southerly" I know a group from a tensor, and in science it is better to be the master of a little mathematics than the slave of much. But what is needed here is not mathematics but a faculty for refusing to be bemused by mathematicians. Unfortunately, this seems to be a rare faculty. Still more unfortunately, it is held in such low esteem in Great Britain that we have the unenvied distinction of being the only major country in the world which has not thought it worth while to join the International Union for the History and Philosophy of Science. It is no accident that we rank high as builders of massive mathematical edifices on rotten foundations. I hope that this small but dangerous one has at least received a shaking.

HERBERT DINGLE

PROF. DINGLE's statements about the work of others are irresponsible. He says I connect "*R*'s estimate for one pair of events with *M*'s for another by the 'Lorentz contraction', which is clearly wrong". The procedure is clearly right, since it is precisely the way in which the Lorentz contraction arises. But the pairs of events named by Dingle are not simultaneous in the reckonings of the respective observers and so are not pairs that can be directly connected by the Lorentz contraction; reference to my work will make it at once obvious that I did not apply the procedure directly to these pairs. On the other hand, if Dingle means merely that I used the contraction in the course of connecting these events, that is all right. Either way, he has detected no error.

Dingle's treatment[1] of Einstein's "most regrettable error" follows the same pattern. (I had not seen this passage of Dingle's before writing my previous reply.) Again he categorically asserts the reverse of the truth. He says Einstein is wrong because he deals with the motion of a clock that is "continuously accelerated and with such motions the special theory of relativity is powerless to deal"[1]. But the truth is that (special) relativistic kinematics, mechanics and electrodynamics deal throughout with motions that are in general continuously accelerated.

As to the result itself that is under discussion, Dingle appears still to assert that there is symmetry between the space-traveller and the stay-at-home. But, were the reversal of the space-traveller's motion sufficiently violent, the space-traveller, not Prof. Dingle, would be killed. Dingle would not be symmetrical with a traveller who turns into a corpse. Since there is obviously not symmetry and, according to relativity theory, there is not universal time, there is no *a priori* reason for the journey to have the same duration by the clocks of the two observers. In general, the journey does not take the same time by the two clocks. This is the immediate consequence of relativity theory that Einstein derived correctly fifty years ago.

The main points mentioned by correspondents concern (*a*) inertial frames, (*b*) accelerations and the behaviour of clocks, (*c*) the resolution of the 'clock paradox'. Other matters raised seem to be outside the scope of the discussion.

(*a*) In classical theory, an inertial frame is one in which Newton's laws of motion hold good; the existence of such a frame is postulated and it is proved that any frame in uniform relative motion, and no other, is an inertial frame. The situation in special relativity is strictly analogous. Some correspondents give the exact quotation from Einstein[2] that Dingle failed to discover. There is not symmetry between *R*, *M* because *R* remains at rest relative to an inertial frame and *M* does not. Dingle implies that *M* cannot identify the event of his ceasing to be in a particular inertial frame. The simplest way of settling the whole argument would be to give Dingle the opportunity to see if *he* would identify a swift change from one inertial frame to another—allowing him thus to "choose the world of experience".

We know how to use inertial frames. We know also, as correspondents remark, that whether or not a particular frame is inertial is determined by its relationship to the universe in the large. But we probably do not adequately understand the physics of this relationship[3]. Dingle could have directed attention to a real problem here.

(*b*) In the example previously considered, the durations of the accelerations could be made arbitrarily short compared with the other times involved. But this served only to simplify the calculation. In the general case there is no mystery about accelerations. If an observer is accelerated in any given possible way, we can integrate the interval along his world-line and so get the proper-time as shown by his ideal standard clock.

Some correspondents think the simple example may be deficient since, they say, *M* could not separate from *R* without producing a reaction upon *R*. This is false because the case would be realized by *M* using rocket-propulsion having no effect on *R*.

Questions are raised about 'biological' time. During acceleration relative to an inertial frame, biological processes need not be synchronized with a standard clock accompanying the system. This is obvious because, as already said, a violent enough acceleration may have fatal consequences. Beyond showing the absurdity of Dingle's views on what events can and cannot be identified, this is not relevant to the discussion. It is on the same footing as the fact that a living organism is not a rigid body. In any case, we could choose accelerations such that, for any given organism, the difference between 'biological' time and clock-time is made proportionately arbitrarily small. That is, the sort of case mentioned by Sir George Thomson could be realized, as regards ageing of observers, as closely as we please.

(*c*) All the foregoing has been known since Einstein's paper of 1905. The communication[4] of mine that has drawn Dingle's attack was a demonstration that these well-known conclusions do not produce a paradox. At least one correspondent reproduces my calculations in full and one detail has to be mentioned. If M treats himself as at rest, I had pointed out that his plot of R's journey shows R moving out to distance αX at speed V, rushing out to distance X and back to distance αX in negligible time, and finally completing his return at speed V; total time $2\alpha T$, where $\alpha = (1 - V^2/c^2)^{1/2}$. Throughout all but the negligible portion of this time, M is in one or other of two inertial frames and plots R as having a uniform speed V; so, by the time dilatation, the parts of R's career so plotted have duration $2\alpha^2 T$ by R's clock. However, between these parts there is also the part that M plots as taking negligible time but that by R's clock makes up the total duration to $2T$. By overlooking this last-mentioned part, other correspondents encountered a difficulty.

I express the results in terms of what the observers would *plot* after making all their observations and allowing for times of light-travel, each regarding himself as at rest. Alternatively, I could have expressed them in terms of what each observer would *see* at each instant in his career. Some correspondents have trouble through confusing these two methods. However, the only thing that matters is that the observers get different descriptions of each other's behaviour, and consequently there is no paradox in their assigning different durations to the journey. The curious details of M's plot of R's behaviour when M treats himself as at rest are not really important, because M will discover that it is much simpler not to treat himself as at rest.

In my previous reply I gave arguments concerning geodesics that are valid in special and in general relativity. In my present reply, I refer only to special relativity. This is correct because, when gravitational effects are irrelevant, the theories are identical.

THE STOICHIOMETRIC RELATIONSHIP BETWEEN AMINO-ACID AND NUCLEOTIDE RESIDUES IN A RIBONUCLEOPROTEIN

By Prof. ERWIN CHARGAFF, Dr. DAVID ELSON* and Dr. HAROLD T. SHIGEURA

Cell Chemistry Laboratory, Department of Biochemistry, College of Physicians and Surgeons,
Columbia University, New York

The statement that there exists some evidence of a relationship between pentose nucleic acid and the synthesis of proteins does not demand the acceptance of one or the other of the numerous 'template' mechanisms that have been put forward[1]. In their usual form, these proposals envisage the condensation of amino-acids along a polynucleotide chain or the simultaneous and interdependent polymerization of nucleotides and amino-acids to form an intermediary nucleoprotein complex from which, for the protein itself to emerge, the nucleic acid would have to be removed, either by dissociation or by degradation. Should an enzyme have been formed in this manner, it would presumably not function before being released from its association with the nucleic acid. The literature contains few systematic studies of the properties of nucleoproteins; but occasional reports of an enhanced enzymic activity of cell preparations or cellular fractions after treatment with ribonuclease[2-4] tend to support this concept. If pentose nucleoproteins are to be regarded as an intermediate stage in protein synthesis, their study assumes added interest.

We wish to present observations made in the initial phase of a study of pentose nucleoproteins from rat liver. Our immediate objectives were: (*a*) the development of a relatively rapid and simple procedure for the purification of pentose nucleoproteins; and (*b*) the examination of the stoichiometric relationship between the nucleotides and the amino-acids present in the conjugated protein. As regards the latter aim, we have pointed out recently[5] that a 'template' arrangement could be expected to impose rather definite restrictions on the relative quantities of the two types of monomer.

The microsome fraction of rat liver[6] served as the source of pentose nucleoprotein. These cytoplasmic structures contain, or are associated with, small granules which appear to be pentose nucleoproteins. (For literature, compare several recent articles[7-10].) For the release of these granules from the microsomes, structures rich in lipids, sodium deoxycholate has often been employed[8,10]—an agent that had been shown previously to produce the cleavage of other lipid-nucleoprotein complexes[11]. This effect is no doubt related to the surface activity and, even more, to the strong complexing ability of this bile acid. The treatment with sodium deoxycholate causes the microsomes to disintegrate, but leaves the small dense granules apparently intact and largely recoverable by high-speed centrifugation. The pellet so obtained

* Present address: Weizmann Institute of Science, Rehovot, Israel.

contains a large part of the pentose nucleic acid, but little or none of the lipid, of the microsomes and a proportion of protein that decreases in measure with the rise in the concentration of deoxycholate.

We have found that a limiting value for the molar ratio of nucleotide to amino-acid is reached at a concentration of approximately 0·5 per cent of a neutral solution of sodium deoxycholate. Moreover, this ratio remains unchanged when the nucleoprotein preparations are subjected afterwards to successive precipitation with ammonium sulphate and with barium and calcium ions.

The suspension of microsomes in 0·9 *M* sucrose solution (isolated from the livers of male Sherman rats weighing about 250 gm. and unfed overnight) was brought to the desired deoxycholate concentration by the addition of a freshly prepared 5 per cent solution of sodium deoxycholate (*p*H 7·3–7·5). The sedimentable material, which in no case comprised more than about one-half of the microsomal pentose nucleic acid, was collected by centrifugation at 105,000 × *g* for two hours. An attempt was made to fractionate such sediments, prepared in 1·6 per cent deoxycholate, by subjecting them to consecutive precipitation with ammonium sulphate, calcium acetate and barium acetate. The latter two reagents may be considered less likely to precipitate protein that did not form an integral part of the nucleoprotein. Data on the composition of the nucleoprotein insoluble at different concentrations of sodium deoxycholate are summarized in Table 1, details of two reprecipitation experiments in Table 2.

For analysis, protein and pentose nucleic acid were separated in the following manner. The material was precipitated or washed with cold 7 per cent trichloroacetic acid, extracted with alcohol-ether, and kept overnight at 30° and *p*H 13–13·5, in order to hydrolyse the nucleic acid to mononucleotides. During this treatment one protein fraction precipitates (Fraction I). For purposes of analysis, this material was not examined separately. The mixture was centrifuged briefly and chilled, and the supernatant fluid acidified to *p*H 5–6 and left in the cold for 15–20 hr., when a second crop of protein (Fraction II) precipitated which was collected by centrifugation. The final supernatant solution was considered as the nucleic acid fraction and the combined precipitates (I and II) were taken as the protein fraction. The effectiveness of this separation procedure was roughly checked by comparing the ultra-violet light absorption of the nucleotide solution at 280 and 260 mμ. The relative values regularly found were those expected of a hydrolysate of pure ribonucleic acid from the cytoplasm of rat liver[12] and gave no sign of contamination by aromatic amino-acids. Direct amino-acid analyses also showed that less than 1 per cent of the total amino-acids was carried into the nucleic acid fraction.

Table 1. COMPOSITION OF RAT LIVER RIBONUCLEOPROTEIN PREPARED AT DIFFERENT SODIUM DEOXYCHOLATE CONCENTRATIONS

Experiment No.*	Final concentration of sodium deoxycholate, per cent	Molar ratio of nucleotide to amino-acid
1	0·4	0·32
2	0·5	0·44
3	0·8	0·53
4	1·2	0·52
5	1·6	0·52
6	1·6	0·44
7	2·0	0·47

* In Exps. 1, 3 to 5, and 7 a Riedel–de Haen preparation of sodium deoxycholate was used; in Exps. 2 and 6 a preparation furnished by A. Maschmeijer, Jr. Inc. When 0·2 per cent sodium deoxycholate was employed, about 90 per cent of the microsomal nucleic acid was recovered in the pellet; with the higher deoxycholate concentrations used here the recovery varied between 40 and 50 per cent.

Table 2. COMPOSITION OF RIBONUCLEOPROTEIN AFTER TREATMENT with DIFFERENT REAGENTS

Experiment No.	Precipitating agent*	Recovery of ultra-violet absorption, as per cent of preceding precipitate	Molar ratio of nucleotide to amino-acid
1	3·2 *M* ammonium sulphate[1]	89	0·50
	0·08 *M* calcium acetate[2]	96	0·49
	3·2 *M* ammonium sulphate[1]	83	0·52
2	3·2 *M* ammonium sulphate[1]	80	0·44
	0·08 *M* calcium acetate[2]	82	0·50
	3·2 *M* ammonium sulphate[1]	90	0·61
	0·08 *M* barium acetate[3]	38	0·56

* The precipitating agent (dissolved in 0·7 to 0·9 *M* sucrose solution to yield the final concentrations listed in the text) was added to the suspension of the preparation in 0·9 *M* sucrose solution and the precipitate collected by centrifugation at 3,000–4,000 × *g*. It was dispersed in the appropriate medium (see following footnotes); the mixture was cleared by low-speed centrifugation; a portion was withdrawn for analysis, and the process was repeated with the next precipitating agent, in the order indicated for each experiment.

[1] 60 per cent saturated at 0°. The precipitate was redispersed in 0·9 *M* sucrose; the solution was subjected to dialysis if barium acetate was to be used next.

[2] The precipitate was redispersed in 0·8 *M* sucrose containing 0·01 *M* sodium oxalate.

[3] The precipitate was redispersed in 0·8 *M* sucrose containing 0·01 *M* sodium sulphate.

The molar nucleotide content of the solution was estimated from the difference of the extinction values at 260 and at 280 mμ at *p*H 7·0. A figure of 1·0 was taken as equivalent to 0·110 micromole of nucleotide per ml.; a value based on observed data and agreeing with the calculated absorption of a mixture of nucleotides in the proportions characteristic of rat liver cytoplasm[12]. The values so obtained were very close to those derived from phosphorus determinations and quantitative paper chromatography[13].

The protein fraction was hydrolysed in 6 *N* hydrochloric acid at 110° for 24 hr. and the residue, resulting from the evaporation of the hydrolysis mixture *in vacuo*, was dissolved in water. The molar amino-acid content was determined colorimetrically by means of ninhydrin[14], with known quantities of alanine or glycine as an internal standard. The values agreed closely with those obtained with external standards and, independently, with the ninhydrin/carbon dioxide technique[15,16].

Some of the properties of the nucleoprotein may be of interest. The two protein fractions mentioned before, namely, Fraction I, insoluble at *p*H 13, and Fraction II, soluble at this *p*H, were present in almost equal proportions. In three preparations, the following figures, as per cent of moles of total amino-acid present in the nucleoprotein, were found for Fraction I: 54, 56, 56. When the ribonucleoprotein was treated with papain[17], it was found that about one-half of the protein moiety was digested. With several specimens, the proportion of protein liberated as amino-acids after a treatment of 4–5 hr. varied from 42 to 57 per cent of the total; no further digestion took place even after 24 hr. The ease of detachment of the nucleic acid from the protein by heat[18] was also studied. When a 0·2 per cent suspension of the nucleoprotein in 0·13 *M* sodium chloride solution was kept near 100° for two minutes almost the entire protein (92 per cent) was precipitated, whereas 60 per cent of the nucleic acid remained in the supernatant fluid.

It will be seen in Table 1 that the molar ratio of nucleotide to amino-acid in the nucleoprotein preparations apparently rises to a limiting value of about 0·5 and remains constant over a fairly wide range of sodium deoxycholate concentration. What is also noteworthy is that this ratio continues essentially unchanged throughout a series of additional mild precipitation procedures (Table 2). It will be understood that we are here concerned only with the number, not the nature, of the nucleotide and amino-acid residues; but it should be mentioned that in a few specimens that were more fully analysed no deviation from the nucleotide proportions previously reported[12] was found.

We conclude that the nucleoprotein preparations under study contained about two amino-acid residues for one nucleotide residue. That this relationship was not changed by successive treatment with different precipitating or solubilizing agents may indicate that virtually all the protein was linked to nucleic acid, though not necessarily all in the same manner. The specific structural significance of this finding must, however, remain obscure until the modes of linkage between protein and nucleic acid and the meaning of the two protein fractions that are distinguishable in the nucleoprotein are better understood. The stoichiometric relationship discussed here is not contradicted by previous analytical findings in the literature[7,8,10,19]; it is of a not unreasonable order of magnitude for a 'template' complex; but it fails to lead to a model as capable of explaining the regularities in the composition of pentose nucleic acids, namely, the equality of the number of 6-amino-nucleotides (adenylic and cytidylic acids) and 6-keto-nucleotides (guanylic and uridylic acids)[5,20], as is the hypothetical arrangement (a polypeptide chain linked to two polynucleotide chains) suggested by us recently[5].

We are very grateful to Mr. H. M. Schulman for technical assistance, to Dr. E. L. Smith for a specimen of the crystalline mercury complex of papain, and to Drs. G. E. Palade and P. Siekevitz for acquainting us with some of their findings before publication. This work, which is being continued, was supported by research grants from the U.S. Public Health Service, the National Science Foundation, and the Rockefeller Foundation.

MECHANISM OF ENTRY OF 5-BROMOURACIL AND ORTHOPHOSPHATE INTO DEOXYRIBONUCLEIC ACID OF *E. COLI*

By Drs. T. D. PRICE, P. B. HUDSON, H. H. HINDS, R. A. DARMSTADT and S. ZAMENHOF

Departments of Biochemistry and Urology, and the Institute of Cancer Research, Columbia University, College of Physicians and Surgeons, and Francis Delafield Hospital, New York 32

STUDIES seeking information on *in vivo* roles of nucleotides in nucleic acid biosynthesis[1] have hitherto proved inconclusive, interpretation of the experimental findings being complicated by difficulty in appraisal of contributions of the following phenomena: (1) the rate of penetration of nucleotides *per se* through cell walls may be low compared to the rates of side reactions[2]; (2) the rate of renewal of the phosphorus of intracellular mononucleotides is generally very high compared to the rate of renewal of the phosphorus of nucleic acids[2-4].

Phosphomonoesterase and phosphotransferase enzymes of high activity are doubtless implicated. The phenomena apparently merit special consideration in the design of experiments on this aspect of nucleic acid metabolism. To eliminate the problem posed by the permeability property, we have used mixtures of traceable, diffusible compounds that are potential precursors of the nucleotides, in place of the isotopically labelled nucleotides employed before[1,2]. To avoid complications resulting from superimposable isotope dilutions of labelled precursor atoms by (*a*) pools of endogenous intermediates, and (*b*) rapidly reversible side reactions, it occurred to us that dilution (*a*) can be eliminated in experiments with biological systems that readily accept a physiologically abnormal base, such as 5-bromouracil, in lieu of a base normally present in their nucleic acid.

Zamenhof and Griboff have described a mutant of *E. coli* that normally requires 5-methyluracil (thymine) for synthesis of deoxyribonucleic acid, but is capable of utilizing 5-bromouracil in reversible replacement of

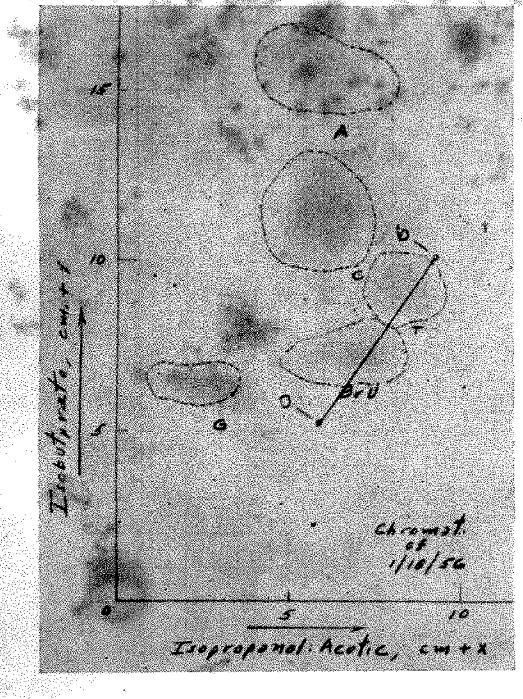

Fig. 1. Radioautograph of a chromatogram containing deoxyribotides of deoxyribonucleic acid from *E. coli* grown from a culture of 5·32–6·46 × 10^{12} cells in a medium with 0·1 mgm./ml. 5-bromouracil and 3 mc. of orthophosphate-^{32}P. *G*, *BrU*, *T*, *C* and *A* identify deposits of deoxyribotides of guanine, 5-bromouracil, thymine, cytosine and adenine, respectively. Measurements shown in Fig. 2 were along line crossing *BrU* and *T*. Photograph taken with radioautograph over labelled centimetre scale

the thymine[5,6]. The main advantage sought by the use of this organism in the present study follows from the possibility of conducting an experiment wherein one of the bases is all newly acquired by the deoxyribonucleic acid. The abnormal base, with the deoxyribose and phosphate to which it becomes attached, can be separated as a unit from enzyme hydrolysates. We reasoned that growth of an originally normal culture from, say, 100 per cent to 120 per cent, in the presence of simultaneously added 5-bromouracil and phosphate-^{32}P, would yield deoxyribonucleic acid with a 5′-isomer of 5-bromouracil 2′-deoxyribotide having specific phosphorus-32 activity markedly dependent upon the source of the phosphorus in this unit of its molecule. On performing the experiment, it was found that the 5′-isomer of 5-bromouridylic acid isolated from the *E. coli* ribonucleic acid had a specific activity comparable to that which would be expected if all its phosphorus is acquired from the medium during the experimental interval.

Bromouracil and orthophosphate-^{32}P were added near the end of the logarithmic stage of growth of strain I *E. coli*[5] in a normal thymine-containing medium[6]. In the typical experiment considered here, the cells were then cultured for 17 hr., during which time the cell count increased 21 per cent. They were lysed with 'Duponol'[6]; crude deoxyribonucleic acid was isolated by conventional means, and treated with 0·3 *N* lithium hydroxide[7] to hydrolyse residual ribonucleic acid and phosphoprotein. After a preliminary development by chromatography with an *iso*butyrate solvent (*p*H 3·6) which moves small-molecule contaminants away from the immobile deoxyribonucleic acid[8], it was eluted, and hydrolysed in 60–80 per cent yield to 5′-mononucleotides employing deoxyribonuclease and arsenate-inhibited intestinal phosphatase[9]. To isolate 5-bromouracil deoxyribotide, Dunn and Smith's[10] electrophoretic separation at *p*H 9·0, and Smith and Allen's[8] two-dimensional paper chromatographic separation were used; the latter system separates all the 5′-monodeoxyribotides (Fig. 1). These compounds were identified by their absorption spectra measured on the paper[11]. Specific phosphorus-32 activity of the nucleotides was determined from measurements of radioactivity and light-absorption of identical fractions[12], the quantity of compound in a measured area of neutral Whatman 3 *MM* paper being computed from a light-diffusion equation that corrects for decrease in the optical depth of a papergram with increase in the concentration of absorber[11,13]. A detailed report on the derivation and use of the practical form of the equation[13] is in preparation. Radiochemical purity was evaluated by constancy of the specific activity at successive areas along lanes of transit[12]. In the illustrative case shown in Figs. 1 and 2, however, the measurements were made along a diagonal line traversing two important deposits. The ordinate values of points in the top graph of Fig. 2 are proportional to specific activity, which may be computed as follows:

$$\text{Specific activity} = R/C = RL\varepsilon/\Delta E \qquad (1)$$

where R is phosphorus-32 radioactivity (counts per min. per sq. cm.), C is concentration (millimoles per sq. cm.), L is optical depth (a dimensionless relative-length variable)[11,13], ε is the conventional molar

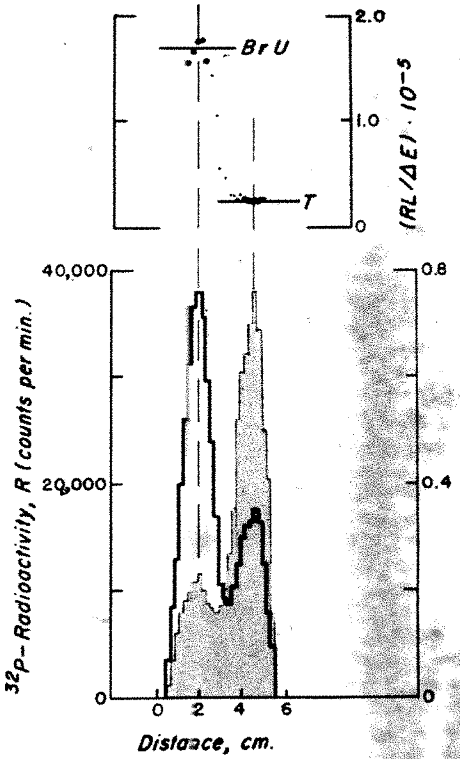

Fig. 2. Open bars: ^{32}P-radioactivity, R. Shaded bars: absorbance of deposited material (ΔE) corrected[13] to a constant optical depth equalling the rectilinear thickness of the papergram, $\Delta E/L$. Circles: ^{32}P-radioactivity divided by corrected absorbance, $RL/\Delta E$. Results from measurement of ^{32}P-radioactivity and absorbance of light of 254 mμ at successive 0·15 sq. cm. areas along line (Fig. 1) through centres of deposits of 5-bromouracil deoxyribotide and thymine deoxyribotide

Table 1. SPECIFIC ACTIVITY OF DEOXYRIBONUCLEOTIDES OF *E. coli* DEOXYRIBONUCLEIC ACID AFTER 21 PER CENT AND 10^3-FOLD INCREASES IN NUMBER OF CELLS

Compound	Specific activity*			
	21 per cent increase		10^3-fold increase†	
	Experimental (*A*)	Relative to 5-BrU (*B*)	Experimental (*C*)	Relative to 5-BrU (*D*)
5-Bromouridylic acid	357 ± 17	100	229 ± 16	100
Thymidylic acid	60 ± 1·2	17	233 ± 12	102
Deoxyribocytidylic acid	104 ± 14	29	214	93
Deoxyriboguanylic acid	130 ± 6·3	37	186	81
Deoxyriboadenylic acid	131 ± 5·1	37	249	109

* Experimental values in columns (*A*) and (*C*) are expressed in counts per minute per millimicromole of nucleotide. Values in (*B*) and (*D*) are relative to 5-bromouridylic acid as 100.

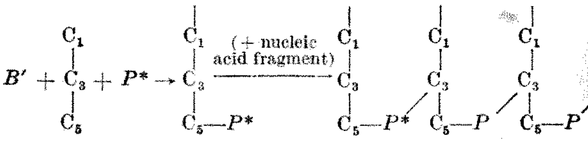
† Theoretically the nucleotides here should be uniformly labelled with phosphorus-32, since virtually all cells were newly formed. Except for the compounds of major interest, 5-bromouridylic acid and thymidylic acid, the values in column (*C*) are results of single measurements. From both theory and results of more critical studies, all values in column (*D*) should be very close to 100.

extinction coefficient (sq. cm. per millemole), and ΔE is absorbance (or optical density) of the measured area with the paper adjacent to the deposit as blank. ε_{264} used for deoxyribotides of 5-bromouracil, thymine, cytosine, guanine and adenine were 4,600, 5,800, 6,000, 13,100 and 13,100, respectively. The specific activity so obtained was multiplied by a factor of 0·447 to correct to a standard phosphorus-32 dosage for the values listed in column *A* of Table 1.

Table 1 shows the results, with those from a control experiment (columns *C* and *D*) where there was a 10^3-fold increase in the number of *E. coli* cells following addition of the bromouracil and orthophosphate-^{32}P at inoculation. After the 21 per cent increase in number of *E. coli*, the specific phosphorus-32 activity of 5-bromouracil deoxyribotide released from the deoxyribonucleic acid as the 5′-isomer is seen to exceed greatly that of any of the other 5′-deoxyribotides. Its isotope concentration at this time was about 50 per cent higher than that of orthophosphate (240 counts/min./millimicromole) isolated from a water extract of the lysed cells. The time curve for specific activity of the 5-bromouracil deoxyribotide of deoxyribonucleic acid is a descending curve, as we would expect if its phosphorus is all newly acquired from labile phosphate of the medium and it enters a deoxyribonucleic acid which has initially no bromouridylic acid. Since the concentration of phosphorus-32 in phosphorus of the labile pool decreases because of continuous dilution with non-radioactive phosphorus that was originally in organic combination with constituents of the cells and the medium used, so also the specific activity of a labile free 5-bromouridylic acid entering the deoxyribonucleic acid must decrease.

The deoxyribonucleic acid of *E. coli* contains the four natural bases in equimolar quantities[14], and the process of replacing thymine by bromouracil is found not to alter this state, providing that the abnormal substituting base is considered as part of the 'thymine'[5,6]. If all the bases enter deoxyribonucleic acid by way of 2′-deoxyribonucleoside-5′-phosphate units, and renewal of phosphorus in these mononucleotides before entry is so rapid that they all quickly have equal specific phosphorus-32 activities, we might expect to find that in the deoxyribonucleic acid the specific phosphorus-32 activity of 'thymidylic acid' (that is, the sum of activities of deoxyribotides of 5-bromouracil and 5-methyluracil in an aliquot of hydrolysate divided by the corresponding number of millimicromoles) should equal the specific phosphorus-32 activity of each of the other nucleotide constituents (column *A*, Table 1). The value found from further data of the typical experiment cited is close, namely, 140 ± 5·3 counts/min./millimicromole. Furthermore, the same practical equality is found to obtain when the increase of *E. coli* cells is 4·4, 35, 121 or 99,900 per cent.

The findings on the 5-bromouracil deoxyribotide of deoxyribonucleic acid demonstrate that there is acquisition of phosphate from the 'labile pool' when 5-bromouracil enters the deoxyribonucleic acid. A reasonable explanation is that the abnormal base (B') and the radioactive phosphate (P^*) become affixed to a pentose at its 1′- and 5′-positions, respectively, forming a 5′-nucleotide, which condenses with the 3′-hydroxyl group of another 5′-nucleotide situated at the end of a fragment of a deoxyribonucleic acid chain, thus :



(2)

where *B* signifies a naturally occurring base, C signifies carbons at reactive positions of the pentose, and *P* is a normal internucleotide phosphate link.

Equation 2 may well depict essentials of the condensation reactions that take place in assembly of the natural nucleotide units of the nucleic acids. Considering effects mentioned in the opening paragraph, data from earlier studies no longer seem to exclude nucleotides (including potentially important nucleoside-5′-pyrophosphates[15]) as the condensing precursor compounds in nucleic acid biosynthesis. Our data on the natural deoxyribonucleoside-5′-phosphate units isolated from the *E. coli* deoxyribonucleic acid were easily reconciled with the hypothesis that they originally entered it as the same units.

The technical assistance of Miss R. De Giovanni and Mr. K. Rich is gratefully acknowledged. The investigation was supported by grants from the Division of Biology and Medicine of the U.S. Atomic Energy Commission, the U.S. Public Health Service, and the American Cancer Society.

Rotation Period of the Planet Venus as determined by Radio Observations

In previous communications, observations of the planet Venus at a wave-length of 11 metres at the Ohio State University have been reported[1]. Based on these and subsequent observations, it has been possible to deduce a probable value for the rotation period of the planet.

As was mentioned, the Venus signals show marked fluctuations in intensity, and during March 1956 the periods of peak Venus activity appeared to group at an interval tentatively estimated as about eleven days. In subsequent observations this tendency has been re-observed, but with the interval appearing to be more like thirteen days. In Fig. 1 the periods of more intense activity during most of June and July 1956 are plotted as a function of the time (E.S.T.) and day of the month. The manner in which the peak activity periods drift from day to day suggests: (1) that the signals originate at a single localized region or several such regions grouped more to one side of the planet, and (2) that the rotation period of Venus is slightly less than one day, this 13-day interval being the beat-frequency rate between the rotation periods of Venus and the Earth; that is, the two planets return to the same relative angular phase every thirteen days. It is assumed that the source regions are relatively fixed with respect to the surface of the planet.

The slanting lines in Fig. 1 indicate the time a fixed source on the planet would cross the central meridian on a given day for the 13-day repetition interval. This interval provides a satisfactory fit with the observations of Fig. 1 and also with data as far back as March 1956. Actually an interval of 12·75 days fits the observations almost equally well. Neglecting second-order effects, the rotation period is given by $24\ [1 - \{1/(N + 1)\}]$ hours, where N is the number of days in the repetition interval. For an interval of thirteen days, the rotation period is 22 hr. 17 min., while for an interval of 12·75 days the rotation period is 22 hr. 15 min.

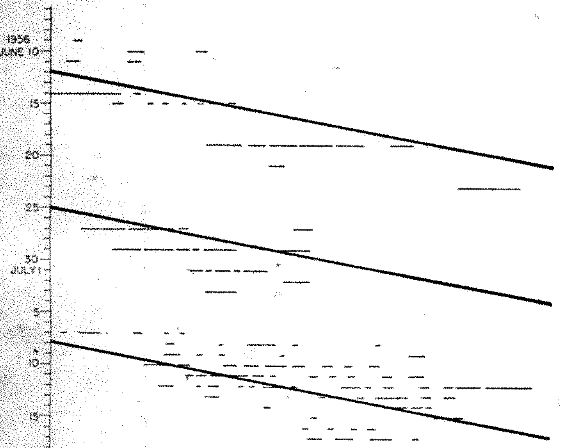

Fig. 1. Periods of peak intensity of 11-m. radio signals from Venus during June and July 1956

For a number of days beginning with July 9, 1956, records were obtained in which the activity peaks appeared to have a particularly distinct pattern which was repeated the following day but 1·6–1·85 hr. earlier, this interval corresponding to the difference between the periods of the Earth and Venus. Daily drifts of 1·6–1·85 hr. correspond to periods of 22 hr. 24 min.–22 hr. 09 min., respectively. These observations make it appear unlikely that the 13-day interval is itself equal to the rotation period, since in this case (13-day rotation period) it is rather improbable that the activity peaks would be repeated each day with a characteristic pattern which advances, on the average, by a fixed time increment each day.

If no correlation is made between a particular peak of activity on one day with a similar one on succeeding days, the data of Fig. 1 show a drift-rate not only of somewhat less than 2 hr. per day but also a drift-rate of about 8 min. per day. A similar rate was reported for the March 1956 data[1]. This rate may be explained as follows. The peaks of Venus activity tend to occur on the average at intervals of about 96 min. (and also half this value), so that a succession of such peaks shows an apparent displacement of 8 min. if displaced each day by 96 + 8 min. This would be the case if the rotation period was 22 hr. 16 min., since the total interval (96 + 8 = 1 hr. 44 min.) is equal to the time Venus gains on each rotation as based on this period.

It may be concluded from the radio observations that a probable value for the rotation period is 22 hr. 17 min., with an uncertainty of about ± 10 min. In calculating these periods the apparent motion of the planet has been neglected. However, the correction due to this is small and uncertain as to sign, since the observations do not indicate the direction of rotation. Since Venus is perpetually covered with clouds, no direct optical observations of the rotation period of the planet have been possible and estimates by indirect means have varied widely[2].

Although the mechanism producing the fluctuations in the signals from Venus is not known, a simple, plausible explanation might be the following. It is likely that Venus has an ionosphere at least as dense as that of the Earth. Radio waves originating on or near the surface of the planet and reaching the Earth would most readily penetrate this ionosphere in the general vicinity of the planet's central point. In this vicinity the ionosphere would appear more transparent to signals travelling earthward, so that, in effect, the ionosphere has a hole. Assuming that the hole remains relatively fixed in position with respect to the central point of the planet's disk, the sources would be observed only as they pass, by virtue of the rotation of the planet, beneath the hole, each source producing a peak of activity as it passes by. A similar ionospheric mechanism is presumed to be responsible for the limited duration of the signals from Jupiter[3]. The fact that the hole has been on the dark side of the planet in recent months (Venus was at inferior conjunction on June 22) would tend to make the hole even more transparent. If the sources are thunderstorms or similar disturbances, which move with respect to the surface of the planet, some variation in the apparent period of rotation may be expected when comparing activity peaks on successive days.

The data in Fig. 1 are based mostly on Venus signals of the atmospherics-like variety (class I), since the class II signals are not observed so frequently. With reference to the latter signals, a recent additional observation is that the pulse-like class II signals occur over a frequency-band of at least 2–4 megacycles per sec. with a given pulse being received earlier at higher frequencies, the dispersion in time being about 2 sec. per megacycle per sec. of frequency difference.

The Second Purple Light

BY photoelectric observation of the twilight sky, Bigg[1] has found evidence of scattering of the Sun's rays from an elevated atmospheric layer. Assuming primary scattering, he calculates its height to average some 81 km. and finds an association between the intensity of the effect and the incidence of meteor showers. He also observed scattering by a lower dust layer (10–25 km.), which is the cause of the purple light frequently observed above the western horizon after sunset and before sunrise. But after some great volcanic eruptions a striking feature of the brilliant sunsets has been the long-continued after-glows, with a second purple light appearing some time after the first had set and only fading away some $1\frac{1}{2}$–2 hr. after sunset.

It is interesting to recall, in the light of Bigg's work, the discussion which took place in *Nature* after the great Krakatoa eruption in August 1883 as to the origin of this second purple light—a discussion continued and amplified in the Report of the Krakatoa Committee of the Royal Society published in 1888. In the first place, R. von Helmholtz[2] suggested that primary scattering of light from dust at heights around 70 km. was the cause of the second purple light; but this view did not gain general acceptance and it was instead held that both purple lights were caused by the lower dust layer. This explanation is still current—Neuberger[3], for example, says "the purple light is sometimes sufficiently intense to cause a secondary purple light for an observer situated farther on the night side of the earth". The primary scattering hypothesis was rejected mainly owing to the "*a priori* improbability that the reflecting stratum, whether derived from cosmical or from terrestrial sources, should occur in two definite layers" (Archibald[4]). Now that we know more of the complexities of the atmosphere and, in particular, of the strong temperature inversion with its base at about 80 km., this argument fails, and Helmholtz's explanation seems much the more probable. The relative intensity of the purple lights seems more in keeping with a two-layer theory; a secondary effect of the first purple light would not be expected to have as great intensity as reported in 1883 and 1884.

If we assume primary scattering from a high-level dust layer, then six observations of the second purple light by Riccò[4] at Palermo give a mean height of 85 km. and others by Brauner[5] at Prague about 80 km. These values compare well with Bigg's mean of 81 km.; so it seems very probable that Krakatoa dust was held in suspension at these heights over a period of some months.

Physical Constants in Extra-Galactic Nebulæ

RECENT wave-length measurements by R. Minkowski and O. C. Wilson[1] of spectral lines of H, N II, O I, O II, Ne III and Ne V for the colliding galaxies identified with the radio source Cygnus *A* permit comparison of galaxy values of physical constants with local values. In particular, radio measures by A. E. Lilley and E. F. McClain[2], in combination with the optical measures, permit estimates on the ratio of galactic to local values of the fine structure constant, α, and the proton gyromagnetic ratio, g. The observed system is estimated to be 3×10^8 light years from us on the Humason, Mayall, Sandage scale[3].

In the discussion of these measures, we shall be concerned with a gross red shift, assumed of the form $\Delta\lambda/\lambda$ = constant, upon which may be superimposed changes in fine and hyperfine structure. It is not necessary to decide whether the gross red shift arises from a change of constants or from a velocity shift. It is further assumed that the interaction Hamiltonian for atomic spectra is of the form:

$$H = H_0 + \alpha^2 H_f + g \frac{m}{M} \alpha^2 H_{hf} \qquad (1)$$

Among these terms, H_0 arises from electrostatic interactions, H_f from relativistic effects usually represented by spin-orbit interactions, and H_{hf} in this specific case is the spin-spin interaction as in the hydrogen hyperfine structure. If we use the ionization energy of hydrogen as the energy unit, we obtain from equation (1) the quantity $hcR = \frac{1}{2}\alpha^2 mc^2$.

In writing equation (1) it is assumed that both fine structure and hyperfine structure are small perturbations, and especially for the former that Russell-Saunders coupling predominates (see Condon and Shortley[4] and Bethe[5]). Note particularly that the ratio of the fine and hyperfine interaction energies to the electrostatic interaction energies depends upon no other physical constants except those indicated in equation (1).

From measures of all available lines, Minkowski and Wilson conclude that for the optical Cygnus *A* the quantity $c\Delta\lambda/\lambda = 16{,}805 \pm 6$ km./sec. The fine structure produces the doublet splitting of the terms ${}^3P_n - {}^1D$. Of the three doublets measured, the measures of O I appear to suffer from blends and only those of N II and Ne III will be discussed. The doublet separations are taken proportional to $(1 + \Delta\lambda/\lambda)\,\alpha^2$. With $\Delta\lambda/\lambda$ as above, we obtain from the data:

$$\frac{(\alpha^2)\ \text{Cyg. } A}{(\alpha^2)\ \text{local}} = 1{\cdot}0036 \pm 0{\cdot}0032$$

E. Salpeter (private communication) points out that if the red shift is understood as arising from a change in α^2, then :

$$\frac{(\alpha^2)\ \text{Cyg. } A}{(\alpha^2)\ \text{local}} = \left(1 + \frac{\Delta\lambda}{\lambda}\right) = 1{\cdot}057$$

The observed wave-length of the hyperfine structure hydrogen line at 21 cm. is assumed to be given by the following equation :

$$\lambda_{\text{Cyg. } A} = \lambda_{\text{local}}\ (1 + \Delta\lambda/\lambda)\ \frac{\left(g\frac{m}{M}\alpha^2\right)_{\text{Cyg. } A}}{\left(g\frac{m}{M}\alpha^2\right)_{\text{local}}}$$

Since Lilley and McClain report $c\Delta\lambda/\lambda = 16{,}700 \pm 50$ km./sec. we find

$$\frac{\left(g\frac{m}{M}\alpha^2\right)_{\text{Cyg. } A}}{\left(g\frac{m}{M}\alpha^2\right)_{\text{local}}} = 1{\cdot}0003 \pm 0{\cdot}0007$$

This corresponds to

$$\frac{\left(g\frac{m}{M}\right)_{\text{Cyg. } A}}{\left(g\frac{m}{M}\right)_{\text{local}}} = 0{\cdot}9967 \pm 0{\cdot}0032$$

It must be mentioned, however, that the difference of 100 km./sec. could also be understood as resulting from an expanding hydrogen envelope of which only the front surface projects on the source.

Note that α is the coupling factor for quantum electrodynamics. The proton gyromagnetic ratio is observed to be 2·8 times the ratio predicted by quantum electrodynamics and is apparently determined by interactions with the meson field. My conclusion is that, within the precision of current measurements, the above physical constants of Nature are indistinguishable in two galaxies 3×10^8 light years apart.

Similar conclusions were mentioned by E. M. Purcell at a symposium in April 1956.

Suggested Experiment on the Relativistic Contraction of Time

It has been questioned whether a discrepancy in time would be observed when comparing clocks at the completion of a space journey. It seems to me that one need not await the advent of space travel at extreme speeds for experimental evidence, since a closely analogous experiment could be performed on the Earth. A suitable clock exists in the form of unstable particles of known half-life. Particles possessing charge in combination with a convenient mass and half-life could be injected into a synchrotron and circulated for a measured time-interval before emerging. Some would disintegrate within the synchrotron and fail to emerge. By comparing the number entering in unit time with the number emerging, any increase in the life of the particles, as measured by the stationary observer, could be determined.

In case it should be objected that motion in a circular path, implying continuous acceleration, does not correspond to a flight path which would be adopted in space travel, an alternative technique is possible. The particles could be accelerated in an electric field, allowed to coast for a relatively long distance in a field-free region, reflected by a second electric field or a magnetic field, and finally brought to rest at the starting point after retraversing the field-free region and the first electric field. To obtain maximum velocities the electric fields could take the form of linear accelerators.

Incidentally, if an increase in life of the particles were in fact observed, there might be interesting applications for this technique of 'freezing' short-lived particles.

A Determination of the Line-width of the λ6300 Line of Oxygen in the Twilight Sky

The red doublet (λ6,300–λ6,363) due to oxygen in the upper atmosphere of the Earth is greatly enhanced in twilight, as was shown by Elvey and Farnsworth[1] and others. The present study has been undertaken to determine the temperature of the emitting layer from the contour of the λ6,300 component.

A Fabry–Perot interferometer with multi-layer dielectric reflecting surfaces, described in an earlier study of the λ5,577 line in the night sky[2], was placed in front of a camera with an effective focal ratio of 3·9. The interferometer plates were coated with five layers—two of cryolite and three of zinc sulphide—giving a reflectance of 0·87 in the spectral region under study. A quartz spacer of 11·7 mm. was used.

In front of the system a multi-layer dielectric interference filter (Baird Associates) with a band-width of 60 A. was inserted to reduce the scattered light from the twilight sky and to isolate the λ6,300 line from the weaker λ6,363 component. The entire instrument was contained in an airtight enclosure to provide constant density of the air between the interferometer plates, and this, in turn, was placed in an insulating case to permit careful temperature control.

Observations were made at the Geophysical Institute at College, Alaska (lat. 64° 52′ N.), at a time when twilight conditions favourable for the study existed at midnight. This permitted long exposures during which the depression of the Sun below the horizon remained nearly constant. Exposures of from one to two hours were necessary to obtain satisfactory results. The optical axis of the instrument was directed to the north and at a zenith distance of 70°.

The instrumental effect on the contour of the fringes was determined from a comparison of the observed line-width with the width of the λ6,438 line

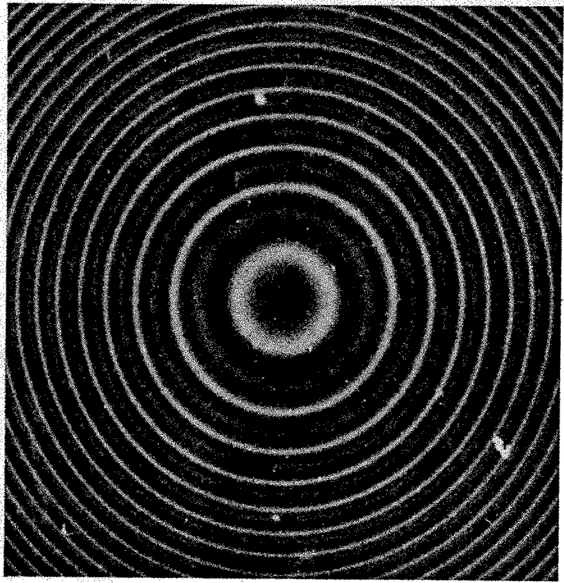

Fig. 1

of cadmium. Periodically the exposure to the twilight was interrupted and the cadmium lamp (Philips type 93107*E*) exposed to the interferometer so that a second set of fringes was formed on the photographic plate. By trial a spacer was found that would give suitable spacing to the two sets of fringes.

Fig. 1 shows the result of a complete exposure (plate *B*): the more intense set of interference fringes are due to λ6,438 of cadmium and the less intense are due to λ6,300 of oxygen.

In the reduction of the line contours, microphotometer tracings made along several diameters of the pattern were converted to intensities and averaged; the several fringes on this average pattern were then converted to a linear scale and combined into a mean fringe for each source.

Using the intrinsic contour of the λ6,438 line, as determined by separate experiment, and assuming the λ6,300 line to be Gaussian in shape, the method of Voigt parameters[3] was employed to find, by a series of approximations, a curve that would best represent the observed curve and would establish the width of the λ6300 line. The instrumental contribution was found to be asymmetrical, with the right side having a resonance shape and the left side a shape intermediate between resonance and Gaussian.

Fig. 2 shows one complete phase of the fringe system: the dotted line is the observed average contour of the fringe system, while the solid line is the best representation of this curve; the dashed lines are the known intrinsic contour of the λ6,438 line and the derived contour of the λ6,300 line. The difference between the solid and the dashed lines represents the instrumental effect.

The zero intensity as shown is probably quite reliable. The overall shape of the fringes and the asymmetry of the instrumental effect combine to restrict the selection of the zero point. It was found that a small change in the zero point would result in a serious deviation in the shape of the curve. This zero intensity is consistent with the minimum intensity of about 2 per cent between the fringes which is to be expected from the reflectance of 0·87 if due consideration is given to the blending of the two sets of fringes.

In listing the results, consideration must be given to the height of the emitting layer, which is that region illuminated by the Sun. However, the height of the horizon for the radiation responsible for the enhancement may very likely be quite great, due to the opacity of the atmosphere; 100 km. has been selected arbitrarily as the height of the opaque layer.

Table 1

	h_0	h_{100}	$\Delta\lambda$	T
Plate *A*	64	155	0·0315 ± 0·0024	790 ± 120
Plate *B*	78	155	0·0299 ± 0·0026	710 ± 130
Plate *C*	74	151	0·0266	560

In Table 1, h_0 is the height of the Earth's shadow in the line of the observation in kilometres; h_{100} is the height of the shadow of a layer 100 km. above the Earth's crust in the line of the observation; Δλ is the width at half-intensity of the λ6,300 line in A.; and *T* is the temperature in degrees K. corresponding to Δλ. The results from plates *A* and *B* are consistent with the probable errors listed. Plate *C*, which shows considerably lower values for Δλ and *T*, has been included only to indicate the order of magnitude of the result; due to fogging of this plate by the twilight, much difficulty was encountered in calibration of the exposure and it cannot be given much weight. A value of 750° K. may reasonably be adopted for the temperature of the emitting layer for the conditions of the first two observations.

This temperature contrasts with the result of the study of λ5,577 of oxygen in the night sky[4], which showed a temperature of about 200° K. Such a difference in temperature would suggest that the emissions in the two cases arise in substantially different levels of the atmosphere: the λ5,577 line in the night sky coming from a level near 100 km., in accordance with evidence from night sky studies[4] and from rocket ascent studies[5], as well as with theoretical argument[6]; the enhanced λ6,300 line in the twilight sky, under the conditions of this study, coming from a level of at least 150 km. and perhaps above 200 km., in accordance with the results from rocket ascent studies[5].

A further discussion of this study will be published elsewhere in the future.

The Maximum of a Distribution- or Spectrum-Function

RECENTLY, Bracewell[1] published a paper, in which he explained why the position of the maximum of Planck's energy spectrum depends on whether the frequency or the wave-length is plotted on the horizontal axis. I wish to direct attention to the fact that this is true for all distribution- or spectrum-functions. Though it is indeed obvious that the maximum must move, when the horizontal axis is non-linearly transformed, yet errors have been made in this respect. Zernike[2] pointed out that, for example, an error of this kind was made when Stern and Gerlach[3] described their famous experiments, in which rays of silver atoms were deflected by a magnetic field. They assumed (Fig. 1) that the atoms with the most probable velocity v_p would have the most probable deflexion y_p (thickest part of the precipitation layer). This is only true if the deflexion y and the velocity v of an atom are related by $y = av + b$. However, they are related by $yv^2 =$ constant. The true value of y_p is one-half of the value derived from the last equation with $v = v_p$. This result is due to Semenoff[4], who was apparently the first to recognize the danger, described here. Though geophysicists are particularly vulnerable in this respect, as they have been investigating spectra of all sorts of time-series, yet almost all of them have succeeded in escaping the pitfall.

One exception is Schumann[5], who obtained the spectrum of the daily air pressure on the North Atlantic by a Fourier analysis. He found $T = 5{\cdot}7$ days as the most frequent period in air-pressure. However, when he changed from period to frequency, he found $n = 0{\cdot}033$ (equivalent to $T = 30$ days) for the maximum of the frequency distribution, a result apparently so strange to him that he looked for an explanation in the wrong direction.

A group of oceanographers from New York University[6] have studied the energy spectrum of ocean waves. In this case, too, the position of the maximum changes when one considers the distribution of periods instead of the distribution of frequencies.

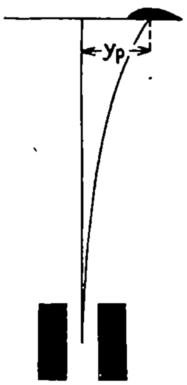

Fig. 1

Spectra of turbulence, especially turbulence of the lower atmosphere, have been analysed by an American group under Panofsky[7] and by an Australian one under Priestley and Swinbank[8]. Both groups have succeeded in avoiding difficulties, though possibly not for reasons inspired by the risk described in Bracewell's paper and here, as is shown by quotations of Panofsky and McCormick (ref. 7, p. 551): "Since meteorological turbulence covers a wide range of frequencies, a logarithmic frequency scale was judged appropriate"; and of Webb (ref. 8, No. 5, p. 7): "It is appropriate to display the results by plotting $n\,F(n)$ which is the fraction of energy per unit fractional increment of frequency. If a logarithmic scale is used for n, the area under a portion of the curve still represents the energy fraction $\int F(n)dn$."

The use of log n or log λ as abscissa ensures that for most cases the spectrum peak frequency and the spectrum peak wave-length are related by $n_{\text{max.}} \times \lambda_{\text{max.}} = c$. This was proved by Bracewell[1] for the case of $c =$ constant. It is also true when $c = c_0\lambda^k$ (this occurs, for example, with waves in deep water, where $k = \frac{1}{2}$); but it is certainly not valid for cases of, for example, $c = c_0 \exp(-\beta\lambda)$.

I wish to express my thanks to my colleague, Dr. H. J. de Boer, for valuable discussions.

Phase-distribution in and near the Bright Nucleus of an Aberration-free Diffraction Image

IT was shown in the course of a recent investigation[1] that the three-dimensional phase distribution very close to the geometrical focus of an aberration-free diffraction image in light of wave-length λ is substantially the same as that in a parallel beam of wave-length $(1 - \frac{1}{4}\sin^2\alpha)\lambda$, travelling in the direction defined by the principal ray, where $\sin\alpha$ denotes the numerical aperture of the converging pencil.

Let φ and $\bar{\varphi}$ denote the respective phases, both normalized to $\pi/2$ at the geometrical focus O, of the complex displacements in the converging pencil and in the parallel comparison beam.

When the numerical aperture $\sin\alpha$ is varied, the form of the equiphase surfaces $\varphi =$ const. undergoes a transformation which is more complicated than a simple linear scale-distortion. However, the difference $\varphi - \bar{\varphi}$ between the phases of the actual and the comparison waves at a point P near focus can be expressed, to a useful approximation, as a function of the two optical parameters u, v alone, where $u/4\pi$ measures the 'number of fringes of defocusing' of P relative to O, and v/π the 'number of fringes of lateral displacement' of P relative to O, as they would be seen in an interferometer. In fact, from the approximate equation,

$$d(P)/d(O) = 2\exp\{-iu\operatorname{cosec}^2\alpha\}\int_0^1 \exp\{\tfrac{1}{2}iut^2\}\, J_0(vt)\, t\, dt \qquad (1)$$

for the ratio of the complex displacement $d(P)$ at a point P near O to the complex displacement at O itself, we obtain:

$$\varphi - \tilde{\varphi} = \omega + \tfrac{1}{4}u - \frac{\pi}{2}, \qquad (2)$$

where

$$\cos\omega = \frac{U_2}{\sqrt{U_1^2 + U_2^2}}, \quad \sin\omega = \frac{U_1}{\sqrt{U_1^2 + U_2^2}} \qquad (3)$$

and the Lommel functions U_1, U_2 are given by the equations

$$U_n = U_n(u,v) = \sum_{m=0}^{\infty}(-1)^m\left(\frac{u}{v}\right)^{n+2m} J_{n+2m}(v) \qquad (4)$$

$$(n = 1, 2).$$

In the course of the investigation already mentioned, the distribution of $\varphi - \tilde{\varphi}$ was computed over the region $u^2 + v^2 \sin^2\alpha \leq 4$, which is a spheroid about 3·5 times as wide and one-sixth as long as the elongated bright nucleus of the three-dimensional diffraction image (see ref. 1, Fig. 4). An extension of the computations, carried out with the assistance of Miss C. P. Wilks, has now made possible the construction of Fig. 1, which exhibits the distribution of $\varphi - \tilde{\varphi}$ over a region about 2·5 times as long, and six times as broad, as the bright nucleus of the diffraction image. Only one (u,v)-quadrant is shown, since the remaining three are readily deducible from it with the help of symmetry relations derived from equation (1).

In this figure, which forms a natural complement to Zernike and Nijboer's well-known diagram[2] of the intensity distribution, Z_1 and Z_2 are the first two axial nodes (points of zero intensity) in the diffraction image, while R_1, R_2, . . . generate the successive Airy dark rings when the figure is rotated about the optic axis Ou. The numbers on the contour lines indicate the values, measured in radians, of the phase-discrepancy $\varphi - \tilde{\varphi}$ between the complex displacements in the diffraction image and in the comparison parallel beam defined above.

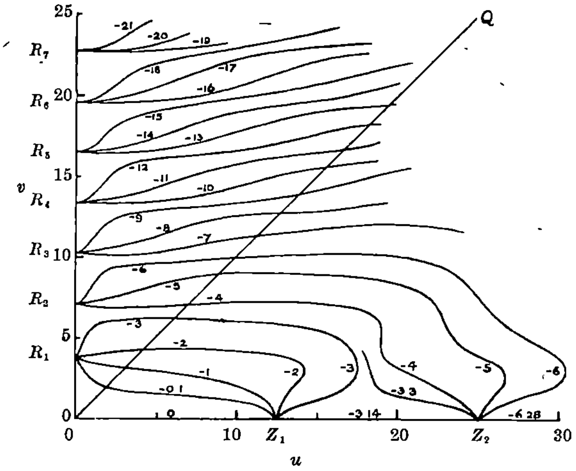

Fig. 1. Values of $\varphi - \tilde{\varphi}$

The diagonal line OQ corresponds to the edge of the geometrical shadow.

A Very Rapid Two-Stage Solid–Solid Reaction and the Mosaic Structure of Potassium Permanganate

Studies of self-sustained reaction by the temperature profile method[1] have recently been extended to compressed mixtures of molybdenum and potassium permanganate and have shown that reaction occurs in two stages.

The observed temperature-time record (obtained by placing a thermojunction in the path of the reaction wave) consists of two sigmoid parts, joined by a flat step which corresponds to completion of the first stage of reaction. When the reactants are initially at room temperature (20° C.), the step temperature is 120° C. and the final temperature 850° C. Thus the heat evolved in the first stage is roughly one-eighth of the total.

This observation may be explained in terms of the mosaic structure of the reactants. If molybdenum ions are the mobile species, as seems probable since they are much smaller than permanganate ions, they may react by diffusing into the permanganate along the grain boundaries. The first stage of reaction probably corresponds to complete coverage of the internal surfaces with a layer of product. No further reaction takes place until the temperature has risen above 120° C.; then, at a temperature at which molybdenum can penetrate the lattice, reaction with the bulk of the permanganate begins. The bulk reaction is expected to be complete because molybdenum is in large excess, and it is probable that the heats evolved in the first and second stages are directly proportional to the numbers of permanganate ions on the surface and in the bulk respectively. On this basis, with the assumption that the surface layer is monomolecular, the average dimension of the mosaic blocks in potassium permanganate may be calculated. It is found to be approximately 10^{-5} cm., which is of the same order as that found in other crystals by X-ray methods[2].

It is apparent that if the mosaic blocks in crystals have dimensions of this order, we may expect roughly 10 per cent of the substance to be in a more reactive state than the rest; and it is noteworthy that partial reaction of this degree is fairly common. Other solid–solid reactions with this behaviour are those between iron and potassium dichromate and between iron and barium peroxide[3]. These are particularly interesting because the reaction time was several hours, or 10^4 times longer than the reaction time (1 sec.) in the self-sustained reaction of molybdenum and potassium permanganate. Similar partial reaction has been noticed during the thermal decomositions of solids, for example, of lithium aluminium ydride[4] and of mercury fulminate[5].

Mass-Spectrometric Detection of the Ion $(SrOK)^+$

In a study of the ionization produced by traces f alkali and alkaline earth elements in hydrogen/air lame gases, Wheeler[1] has found evidence for ions of he type $(BOA)^+$, where A represents an atom of lkali metal and B one of alkaline earth. Theoretical alculations, by the method of Rittner[2], suggest that uch ions should be of high stability in the gas hase, the heat of dissociation into BO and A^+ being f the order of 100 k.cal./mole. A mixed ion of this ype was suggested by the highly specific behaviour iven by various A/B pairs. The basic measurements ere, however, of electron concentrations, the xistence of this particular positive ion being in-erred from them, and it seemed desirable to have ndependent and more direct evidence for their resence.

An attempt to obtain and identify such ions has een made by mass-spectrometric analysis of the nic content of the vapour from a strongly heated ixture of a potassium and a strontium salt in a acuum oven. The diagram of the oven is shown in ig. 1. The oven cell (A), of molybdenum, was contructed in two pieces, rammed together after loading ith the charge (B). It was maintained at a potential f + 1,500 V. (stabilized) relative to the remainder f the oven, this serving to accelerate the ions into he mass spectrometer, and also allowing the front nd to be heated to the required temperature by lectron bombardment from the filament (C). A econd filament (D) allowed of further heating (of he rear end) by radiation. The temperature of the ront (exit) end of the oven was determined pyro-etrically, and that of the rear by a thermocouple E), which also carried the emission current, via the ven, from (C). The inner radiation shields (F,G) ere of nickel, and the outer, water-cooled, shield (H) as of copper.

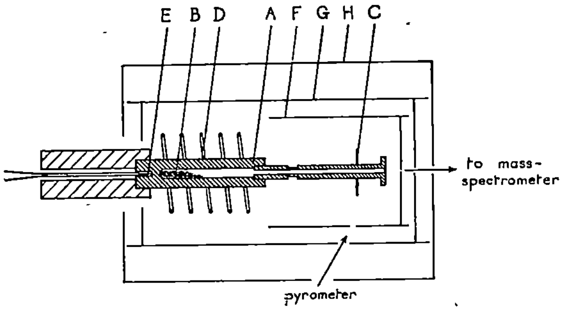

Fig. 1

Any positive ions in the vapour from the charge ere repelled from the oven, through the slit system, nto a mass spectrometer, which was a 90° Nier type. n electron multiplier detection system was used so hat actual counts of ions could be made. A mixture f strontium and potassium carbonates was heated, a ttle cæsium being added to give a reference peak t mass 133. With this mixture, the rear of the oven eing at about 1,000° K., and the tip at about ,900° K., which were found to be optimum working onditions, an ion current was noted at mass 143. his was not evident with either of the carbonates heated alone under the same conditions. It corresponds with a positive ion $(^{88}Sr^{16}O^{39}K)^+$, which combines all the most abundant isotopes, and should give at least eight times as large a peak as any other combination. The observed peak corresponded with a current of about twelve ions per sec., with a noise-level of about two per sec., so that no other $(SrOK)^+$ peak would be expected.

It is considered that this provides reasonable evidence for the existence of this type of ion, first postulated in the flame studies referred to. The ions probably owe their stability to the very large electrostatic attraction between the alkali metal ion A^+ and the large dipole of the alkaline earth oxide BO. It is interesting to note that Inghram, Chupka and Porter[3], also using a mass-spectrometric method, have been able to demonstrate the formation of the ion $(Ba_2O)^+$ from the vapour of barium oxide heated in an alumina crucible.

One of us (P. F. K.) is grateful to the Department of Scientific and Industrial Research for a grant covering the period of this investigation.

Isolation of the Stable Boron Trifluoride – Hydrogen Fluoride Complexes of the Methylbenzenes ; the Onium Salt (or σ-Complex) Structure of the Friedel-Crafts Complexes

The alkylation of aromatic hydrocarbons catalysed by aluminium chloride and similar Friedel-Crafts catalysts is ordinarily accompanied by the formation of deeply coloured oily liquids of high density. The structure of these 'Friedel-Crafts complexes' has been investigated by a number of workers[1]. H. C. Brown and H. W. Pearsal[2] have proved the formation of a molecular complex from toluene and aluminium chloride – hydrogen chloride at low temperature. In further work, H. C. Brown and J. D. Brady[3] have established the structure of the hydrogen chloride – aluminium chloride complexes of the methylbenzenes as σ-complexes in contrast to the proposed hydrogen chloride complexes which have a π-complex structure (after the representation of Dewar[4]). The formation of the onium or σ-complexes was proved by Brown by the hydrogen chloride technique by measuring the solubility of hydrogen chloride in the presence of aluminium chloride in the isomeric methylbenzenes.

Similarly, the complexes of hydrogen bromide – aluminium bromide with aromatic hydrocarbons have been intensively investigated. Norris reported the isolation of several crystalline products from mesitylene (Mes) and 1,3,5-triethylbenzene (TEB) with aluminium bromide – hydrogen bromide: 3Mes.Al_2Br_6.HBr ; 2TEB.Al_2Br_6HBr [5] ; Mes.Al_2Br_6.HBr ; TEB.Al_2Br_6.HBr [6]. Brown and Wallace[7] suggest, as a result of their investigations of hydrogen bromide – aluminium bromide complexes of aromatic hydrocarbons, the σ-complex structure of the resulting Friedel-Crafts complexes ('red oils').

The concept that aromatic hydrocarbons possess basic properties sufficiently strong to form salts with hydrogen halide – aluminium halide and similar reagents suggests that such reagents could be utilized to extract, preferentially, more strongly basic aromatic hydrocarbons from those less basic. McCaulay, Shoemaker and Lien[8] have recently demonstrated that hydrogen fluoride – boron trifluoride can be readily utilized to extract the more basic *m*-xylene from its mixture with the less basic *o*- and *p*-xylene isomers. These authors have established the ratio Ar : BF_3 = 1 : 1 in the complexes formed from aromatic hydrocarbons, boron trifluoride and hydrogen fluoride, the latter being present in excess as the solvent. The formation of the complexes was proved by the determination of the solubility of boron trifluoride in the hydrogen fluoride – methylbenzene system.

We have now been successful in isolating the stable boron trifluoride – hydrogen fluoride complexes of the methylbenzenes in the previously investigated cases of toluene, *m*-xylene, mesitylene and *iso*durene.

In the absence of hydrogen fluoride and at low temperature (– 25° to – 85°), boron trifluoride neither interacts with nor dissolves appreciably in toluene, xylene, mesitylene and *iso*durene. Hydrogen fluoride itself is also not soluble to more than 1 per cent in the methylbenzenes[9]. In the presence of an equimolecular quantity of water-free hydrogen fluoride, the boron trifluoride dissolves in methylbenzenes to give a clear solution with a bright colour (greenish-yellow, yellow or brownish-red), which solidifies by cooling. The one mole of methylbenzene, one mole of hydrogen fluoride and one mole of boron trifluoride is needed to form the stable complex. The reaction is reversible: when heated, the complexes melt with subsequent evolution of boron trifluoride and hydrogen fluoride and the aromatic compounds are regenerated. We were able to determine the melting points of the stable methylbenzene hydrogen fluoride – boron trifluoride complexes in the cases of toluene, *m*-xylene, mesitylene and *iso*durene. Also the specific conductivity of the stable complexes were determined.

PROPERTIES OF $ArH^+BF_4^-$ COMPLEXES PREPARED

R	Melting point (° C.)	$\varkappa$ Ω^{-1} cm.$^{-1}$
$(CH_3)C_6H_5$	–65	0 8 × 10^{-2}
m$(CH_3)_2C_6H_4$	–55	2·0 × 10^{-2}
s$(CH_3)_3C_6H_3$	–15	1 6 × 10^{-2}
as$(CH_3)_4C_6H_2$	–10	0 6 × 10^{-2}

The reaction is believed to involve the formation of a carbonium ion salt of the hypothetical acid, HBF_4 : $(CH_3)C_6H_5 + HF + BF_3 = (CH_3C_6H_6)^+BF_4^-$. The complexes which are formed in the course o Friedel-Crafts reactions are believed to be carbonium ion salts of this kind.

Using deuterium fluoride (prepared by the reaction of C_6H_5COF with deuterium oxide[10]) in the place of hydrogen fluoride in the complex formation, deuterated tetrafluoroborate complexes of the $(CH_3C_6H_5D)^+BF_4^-$ type are formed. By the slow decomposition of the complexes we obtain *o*- and *p*-D-toluene, which confirms unambiguously the electrophilic character of the D^+ substitution via the stable onium ion salt of the hypothetical DBF_4 acid and the structure of the complexes.

Notation for Serum-Protein Groups and the Genes controlling their Inheritance

SEVERAL workers[1–3] have described the presence in serum of a protein with the striking characteristic of binding hæmoglobin. During electrophoresis on filter paper, this hæmoglobin-binding protein migrates in the α_2-globulin position. It is the haptoglobin o Jayle *et al.*[1]. The serum-protein groups described by Smithies[4,5] are characterized by several protein demonstrated by electrophoresis in starch gels which also have this property of binding hæmoglobin. They appear to be the only serum proteins with hæmoglobin-binding powers. Furthermore, they also migrate in the α_2-globulin position when the electrophoresis is carried out on filter paper[5,6]. Consequently, the identity of haptoglobin and the proteins characterizing the serum groups can be regarded as established, even though previous work had no shown the multiple nature of haptoglobin. Th serum-protein groups are therefore basically determined by differences in the haptoglobins of differen individuals.

A genetic pattern for the inheritance of the serum protein groups has been outlined by us in a previou communication[7]. More extensive family studies in which all possible matings have been observed confirm this mode of inheritance—namely, that th serum groups are determined by two autosoma genes with incomplete dominance. Complicatin factors which we intend to discuss in a comin publication may make it necessary in the future t extend this genetic mechanism; but its essentia correctness is, we believe, established.

Since differences in the haptoglobins of individuals determine their inherited serum groups, we suggest that the system comprising these groups be known as the 'haptoglobin system'. If other inherited serum groups are discovered in the future, the systems can also be named according to the nature of the proteins concerned. We should like to stress that the demonstration of serum-protein groups makes it necessary to distinguish two classes of blood groups: the red blood-cell class (with the corresponding serum antibodies when these are present), and the serum-protein class which does not involve the red cells[7]. To assist in distinguishing the two classes, we propose that serum-protein groups be described by the name of the system followed by numerals to designate the specific group, thus contrasting with the use of letters in the red-cell groups.

In describing the genetic pattern for the haptoglobin system, we suggest that the locus symbol be *Hp* and the genes Hp^1 and Hp^2. The notation for the system would then be as follows:

HAPTOGLOBIN SYSTEM OF THE SERUM PROTEIN GROUPS

Old nomenclature	New nomenclature	Genotypes
Group I	Haptoglobin 1–1	Hp^1/Hp^1
Group II*A*	Haptoglobin 2–1	Hp^2/Hp^1
Group II*B*	Haptoglobin 2–2	Hp^2/Hp^2

A summary of some of the factors which were considered in selecting this notation may be given:

(i) The use of numerals prevents confusion between red-cell groups and serum protein groups.

(ii) The new names for the serum-protein groups have the advantage of indicating the specific proteins which distinguish the three serum groups, and yet they are close to those originally used in describing them. Thus haptoglobin 1–1 (one–one) is similar to group I; haptoglobin 2–1 (two–one) to group II*A*; and haptoglobin 2–2 (two–two) to group II*B*.

(iii) The names given to the three phenotypes correspond closely to the respective genotypes.

(iv) The close similarity of the haptoglobins 2–1 and 2–2 (which differ considerably from haptoglobin 1–1) is reflected in the names.

(v) The relative rates of migration in starch gels of the haptoglobins of the three groups are implied by the numbers, since haptoglobin 1–1 migrates considerably more rapidly than haptoglobins 2–1, and these in turn migrate slightly more rapidly than haptoglobins 2–2.

(vi) If further work indicates that either of the alleles representing the haptoglobin system is multiple, the notation can readily be extended to show this by using subscript letters to the numerals (for example, 2_a, 2_b, etc.) to describe the subgroups in the way that subscript numerals are used with letters in the red-cell groups (for example, A_1, A_2, etc.).

In describing blood groups, there are occasions when the use of an abbreviated form is essential, so it seems advisable to suggest standard abbreviations for the haptoglobin system at this juncture. The three types can readily be abbreviated to *Hp* 1–1, *Hp* 2–1 and *Hp* 2–2.

We are grateful to Dr. Helge Laurell, of the University of Upsala, for directing our attention to the work on haptoglobin, and for the suggestion in a private communication to one of us that this protein might be identical with one of the hæmoglobin-binding substances of serum demonstrated by starch-gel electrophoresis. We wish to thank Drs. Bruce Chown, William Donohue, Harold Gunson, Philip Levine and Ruth Sanger for their helpful comments on the notation here proposed.

Hæmoglobin *E* in Malaya

Of the variants of normal adult hæmoglobin (*A*), four are now known to be present in large numbers of people. Sickle-cell hæmoglobin (*S*) is found in tropical Africa, in some Mediterranean and Middle Eastern countries and in the New World in populations derived from these parts. It is also present in a few aboriginal communities in southern India. Hæmoglobin *C* is frequent in West Africa, where it is at its highest incidence in the northern Gold Coast. Hæmoglobin *D* has been found in India in 3 per cent of north-west Indians and in 1 per cent of Gujeratis.

Hæmoglobin *E* is present in Siamese[1], Burmese[2] and in Indonesians[3]. In Ceylon it was found in some aboriginal Veddas but not in the Singhalese themselves. Single instances have been seen in India, Turkey, Persia and in the Philippines, but none has so far been found in the Chinese[1,3].

It was of interest to see whether the Malaysians were similar to their Burmese and Siamese neighbours in the north, where hæmoglobin *E* was found in 15·3 [2] and 13·6 [1] per cent respectively, or whether they resembled the Indonesians in the south, where the incidence is 2·9 per cent[3].

We have examined the blood of 346 Malaysians, all non-related, and have found twenty-four to show hæmoglobins *A* and *E*, one hæmoglobins *F* and *E* (hæmoglobin *E*: thalassæmia), and one hæmoglobin *E* only (hæmoglobin *E* disease). With an incidence of 7·3 per cent, the Malaysians are somewhere midway between the Siamese and Burmese in the north and the Indonesians in the south.

Table 1 suggests that there is a gradient even within Malaya. The peninsula is divided into an eastern and western part by a central range of mountains. Most of the immigrants from Indonesia, especially Sumatra, have settled in the south (Johore) and west of the range of mountains, which acted as a barrier to settlers from across the Straits of Malacca. It seems that there is an inverse relationship between the extent of Indonesian admixture in the past and the incidence of hæmoglobin *E*. In the southern parts of the Western States of Malaya, only one person with this hæmoglobin was found among fifty-four examined from Negri Sembilan, Malacca and Johore.

In one person—from Kelantan—part of the hæmoglobin was neither *A*, *F* nor *E*. The electrophoretic mobility and the progressive denaturation

Table 1. HÆMOGLOBIN *E* IN MALAYSIANS IN MALAYA

State	No. examined	No. with hæmoglobin *E*	Per cent

Johore	21	–	0
Total	346	26	7·5

of the purified hæmoglobin by freezing and thawing were properties described for hæmoglobin *H*, first seen in a Chinese family in the United States[4].

We hope to continue this survey, and to extend it to other communities of Malaya—of three aborigines so far examined one, a Senoi, showed hæmoglobins *A* and *E*. It seems already that the distribution of hæmoglobin *E* in Malaya follows an ethnological pattern, as was noted for that of sickling in Uganda[5] and of hæmoglobin *C* in the Gold Coast[6] and in Nigeria[7].

Oxidation *in vitro* of Radioactive Œstradiol by Preparations of Human Tissue

THE oxidation of œstradiol to œstrone and œstriol in the pathway of degradation of the œstrogens has been inferred from *in vivo* studies in which œstrone and œstriol were found in the urine of the male human[1] and œstrone in the urine of other mammals[2] after the administration of large amounts of œstradiol. More recently, Ryan and Engel[3] found an *in vitro* interconversion of œstradiol and œstrone by tissue-slice preparations of several organs of the rat and man. Using counter-current distribution to achieve separation of the steroids, an accumulation of either œstradiol or œstrone was found when the other œstrogen was present in the substrate. These workers were not able to demonstrate formation or utilization of œstriol. We have observed the *de nov* formation of œstrone and œstriol from labelle œstradiol by human-tissue slice and homogenat preparations from a variety of organs.

Tissues obtained from surgical specimens wer placed in cold phosphate–nicotinamide buffer[4] immediately after excision. The sera used were freshl obtained pooled sera from the individually centrifuge blood specimens of several female donors. Tissu slices were suspended in 5 volumes of buffer ; homogenates were a 20 per cent suspension in buffer ; an sera were diluted in 20 volumes of buffer. 7 ml. of tissue preparation and 1 mgm. adenosine monophosphate, 1 mgm. diphosphopyridine nucleotide an 0·10 mgm. œstradiol-16-^{14}C (2 μc./mgm.) were place in each flask and incubated at 37° C. under oxyge for 2½ hr. After incubation, 0·15 gm. metaphosphori acid, 0·5 gm. 'Celite' and 3 gm. sodium chloride wer added to each flask. 10·0 mgm. of carrier, eithe œstrone or œstriol, was then added.

The œstrogens were isolated from an ether extrac by the paper chromatographic procedure of Mitchel and Davies[5]. The area which contained the sampl and which corresponded to authentic œstradiol œstrone or œstriol was cut out and extracted wit alcohol. This alcoholic extract was evaporated t dryness in planchets, weighed and assayed fo specific radioactivity.

Table 1. OXIDATION OF ŒSTRADIOL-^{14}C BY VARIOUS TISSUES

System		Œstrogen recovered (range (counts/min.)/mgm.)	
		Œstrone	Œstriol
Ovary	Slice	4,970–6,139	187–203
	Homogenate	5,130–7,100	87–130
Testis	Slice	3,470	0–4
	Homogenate	4,150	0–4
Liver, male, homogenate		6,350–7,800	20–88
Kidney, male, homogenate		335	—
Muscle, male, homogenate		245	0–18
Serum		30–60	20–84
Blank		20–38	30–37

Liver, ovary and testis preparations, in this order are highly active in converting œstradiol to œstrone kidney and muscle preparations are less active. Th conversion to œstriol occurs in ovarian preparations and to a lesser degree in preparations of liver. Ther is no or negligible conversion in pooled female-bloo serum. The homogenates were as active or perhap slightly more active than comparable tissue-slic preparations.

The incorporation of acetate-^{14}C into œstradiol b tissue preparations of dog ovary prior to its incorporation into œstrone[6] is consistent with the concep that œstradiol is the œstrogen primarily synthesize in the ovary, and that œstrone and œstriol are the formed by oxidation.

Pseudo-cholinesterase in Rat Erythrocytes

Although there are many references in the literature to the existence of different types of cholinesterase in mammalian sera[1], it is generally believed that human red cells contain only one type[2]. Furthermore, we can find no evidence in the literature for the existence of a pseudo-cholinesterase in any mammalian erythrocytes, although many workers have stated that benzoylcholine is hydrolysed by red cells. Since, however, the rate of hydrolysis is slow, this breakdown of a substrate formerly presumed to be specific for pseudo-cholinesterase has been attributed to true cholinesterase. Indeed, Adams[3] has shown that purified true cholinesterase does hydrolyse benzoylcholine, at a rate which would account for such observations. In spite of this, some results obtained by Fraser with benzoylcholine[4] imply the existence of more than one type of cholinesterase in red cells.

Experiments which we have recently carried out on erythrocytes twice washed with 0·9 per cent sodium chloride demonstrate quite clearly the existence of a true and pseudo-cholinesterase in rat red cells. The latter differ markedly from human erythrocytes in that they hydrolyse butyrylcholine as rapidly as acetylcholine (Table 1).

Table 1. Relative Rates of Hydrolysis of Choline Esters by Rat and Human Red Cells

	Acetylcholine	Acetyl-β-methylcholine	Butyrylcholine	Propionylcholine
Rat	100	85	101	79
Human	100	78	10	63

This hydrolysis of butyrylcholine can be suppressed by tetra*iso*propylpyrophosphoramide at a concentration (2×10^{-4} *M*) which does not inhibit the hydrolysis of acetyl-β-methylcholine to any marked extent. Tetra*iso*propylpyrophosphoramide is an inhibitor which has been shown[5] to be specific for pseudo-cholinesterase. 1 : 5 - bis - (4′trimethylammonium-phenyl)pentan-3-one diiodide (62*C*47 Wellcome), a specific inhibitor of true cholinesterase[6], at 7×10^{-5} *M* inhibits the hydrolysis of acetyl-β-methylcholine but not of butyrylcholine.

Table 2. Inhibition of Hydrolysis of Choline Esters by Rat Red Cells in the Presence of Inhibitors of True and Pseudo-cholinesterase

Inhibitor	Per cent inhibition (calculated from the ratio of hydrolysis-rate in the presence, and absence, of inhibitor for the given substrate)			
	Acetyl-choline	Acetyl-β-methylcholine	Butyryl-choline	Propionyl-choline
Tetra*iso*propylpyro-phosphoramide	20	15	100	30
62*C*47	92	97	0	45

We have insufficient evidence to enable us to draw any definite conclusions concerning the nature and source of the pseudo-enzyme. For example, we cannot say whether it is similar to, or derived from, the serum enzyme. It is certainly firmly attached to the cells, since it cannot be easily washed off. All the experiments quoted were done on pooled erythrocytes of male rats; hence the presence of this enzyme in female red cells has yet to be established. The precise type of pseudo-cholinesterase, too, is a matter for speculation. The almost complete lack of activity towards benzoylcholine makes it most unlikely that it is a benzoylcholinesterase[7], and the low propionylcholine to acetylcholine ratio of 0·8 would appear to rule out the possibility of a propiono-cholinesterase such as that found in rat heart[8], and which has a corresponding value of approximately 2·3. On the basis of its substrate ratio, it is possible that it may be a butyro-cholinesterase.

Receptor Occupancy and Tissue Response

One of the cornerstones of all quantitative applications of classical receptor theory has been the postulate that the response of a given organ or tissue is proportional to the number of receptors occupied by the activating agent, and that the maximal response occurs when all receptors are occupied. Although never proved experimentally, and perhaps *a priori* somewhat unlikely in view of the complex nature of tissue responses, this relationship is necessary if agonist dose – response curves are to be explained in terms of mass-action equilibria, and it provides the basis for differentiating reversible competitive from non-competitive or irreversible inhibition. Basic formulations applying mass-action considerations to the differentiation of types of inhibition are those of Gaddum[1], applied largely to tissue and organ responses, and of Linweaver and Burke[2], which have been applied both to relatively simple enzyme systems and to complex responses of tissues and of intact animals.

In general, use of the Linweaver–Burke equations to evaluate data obtained from studies on enzyme systems has proved satisfactory. However, some fundamental error in the application of these equations to data obtained from experiments on intact animals or isolated tissues is suggested by reports which classify the β-haloalkylamines (dibenamine congeners) as reversible competitive blocking agents on this basis[3]. Except at high concentrations of the inhibitor, data for the blockade of responses to adrenaline or histamine by these agents are typical of reversible competitive inhibition when plotted by either of the methods mentioned above. This observation conflicts with several lines of evidence which indicate that the blockade, although it is ‘competitive’ in the sense that the agonist and the antagonist react with the same receptors, is predominantly irreversible because of a stable bonding of the inhibitor to some tissue constituent in the area of the receptor[4].

Two types of experiments have been combined in the present study to provide a possible explanation for the above discrepancy. Isolated strips of guinea pig ileum were exposed to *GD*-121 (*SY*-14, *J*10; N-1-naphthylmethyl-N-ethyl-β-chloroethylamine) for 5 min., and the degree of blockade of the isotonic

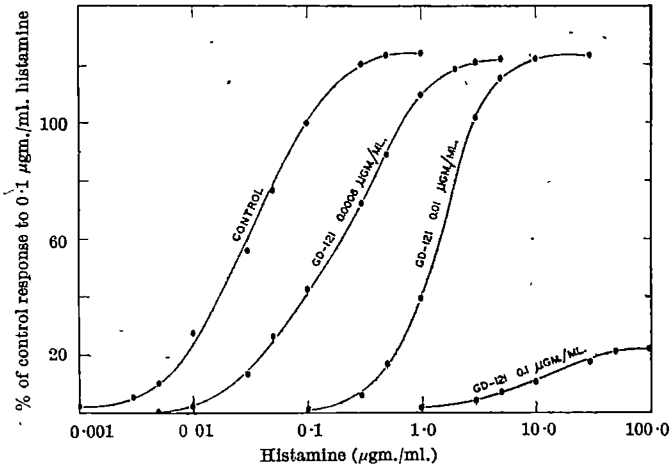

Fig. 2

response to a standard dose of histamine (0·1 μgm./ml.) was then determined in the presence of the inhibitor and after successive washes at 5- and 10-min. intervals. As shown in Fig. 1, a minor portion of the blockade was readily reversible; but the blockade remaining after 10 min. was essentially irreversible to washing. Some experiments were continued for as long as 8 hr. without a significant change in the slope of this line. As shown in the figure, histamine or diphenhydramine (benadryl) introduced prior to the *GD*-121 prevented the development of irreversible blockade, indicating that all three agents react with the same receptors. On the basis of these experiments, it may be concluded that in tissue treated with *GD*-121, a portion of the specific histamine receptors are inactivated essentially irreversibly, providing a relatively long period during which responses of a tissue with a reduced number of free receptors can be studied.

Histamine dose – response curves were then determined on untreated ileum and on segments exposed to varying concentrations of *GD*-121 and washed to remove blocking agent not irreversibly bound. The response of each preparation to a standard dose of 0·1 μgm./ml. of histamine prior to blockade was arbitrarily designated as 100 to facilitate compilation of results. In both figures, each point represents the average of six to ten separate determinations. It was found (Fig. 2) that the histamine dose – response curve could be shifted at least 2 log units along the agonist dose axis by low concentrations of *GD*-121 without changing either its slope or asymptote significantly[5]. Higher concentrations of *GD*-121 decreased both. These curves, except that on the extreme right, are characteristic of reversible competitive antagonism when plotted according to the equations of either Gaddum or Linweaver and Burke—an interpretation obviously incompatible with the results of the preceding experiments.

These observations can best be explained by assuming that receptor occupancy is not the limiting factor in the tissue activation, and that occupancy of only about 1 per cent of the histamine receptors is adequate to produce a maximal response. As the total number of free receptors is progressively decreased by irreversible combination with blocking agent, larger concentrations of agonist are required to provide the receptor occupancy necessary for any given response. Ultimately, the total number of free receptors is reduced below that required for a maximal response even when they are saturated by a very high concentration of agonist. This formulation explains why classical dose – response plots erroneously indicate reversible competitive antagonism at low, and irreversible or non-competitive antagonism at high, concentrations of a β-haloalkylamine. It does not necessarily imply that responses are not proportional to the number of receptors occupied over most of the response range. However, the evidence that receptor occupancy is not necessarily the limiting factor in determining the magnitude of a tissue response suggests that all theoretical deductions from mass-action analyses of dose – response curves should be accepted with caution.

This investigation was supported by grants-in-aid from the Canadian National Research Council and the Smith, Kline and French Laboratories.

Ammonia Production in the Collecting Ducts of Mammalian Kidneys

COMPARED with other parts of the nephron, the cells of the collecting ducts are morphologically conspicuous by the absence of any particular differentiation. This has led to the assumption that their function is exclusively mechanical, that is, to convey the urine from the distal part of the nephron to the renal pelvis. Physiologists have not been able to assign any active cellular function to this part of the nephron though Glimstedt[1] and Wirz[2] presented convincing evidence for its importance in water reabsorption and we have suggested[3] that back-diffusion of ammonia might occur in this segment. Both these functions are presumably of physico-chemical nature and independent of cellular activity.

In good agreement with this morphological and physiological undifferentiation are the results of biochemical investigations. Dickens and Weil-Malherbe[4]

showed that renal medulla is one of the few adult mammalian tissues having a high aerobic glycolysis. Weil and Jennings[5], using the Linderstrøm-Lang technique, provided evidence that the collecting ducts are almost devoid of cathepsin, dipeptidase, amino polypeptidase, esterase and amylase. Histochemical studies have indicated the lack of active SH-groups, glycerophosphate dehydrogenase, adenosine triphosphatase, glucose-6-phosphatase, alkaline and acid phosphatase, lipase, esterase and succinic dehydrogenase in the lower part of the collecting ducts[6]. These studies, especially the observation of high glycolysis, indicate a low level of biochemical differentiation.

During investigations of the ammonia excretion in different mammalian species[3], it was observed that under different experimental conditions ammonia excretion correlated particularly well with glutaminase I activity of the kidney. To localize this enzyme, kidneys of different species were dissected into cortex, outer medulla and inner medulla and each part analysed using histological and biochemical methods. In this report the results of the analyses of two species, dog and rabbit, as representatives of animals with very high and very low ammonia excretion are presented (Table 1).

Determination of the dry weight of the different parts of the kidney showed marked differences, the cortex giving the highest, the papilla the lowest values. Such an analysis makes it very simple to check the quality of the dissection. The activities of glutaminase I [7], the transamination–deamidation system[7] and glutamine synthesis[7] were measured in homogenates of different parts of the kidney under optimal conditions[8].

Glutamine synthesis from glutamic acid, ammonia and adenosine triphosphate in the presence of magnesium and at a pH of 7·5 was found to be largely a function of the cortex. The renal transamination–deamidation system which liberates ammonia from glutamine in the presence of α-keto acids is optimal at pH 8·8. This enzyme system was localized primarily in the cortex of the dog and in the outer medulla and cortex of the rabbit. It may well be that these two systems participate in the process of amino-acid reabsorption.

Glutaminase I, a phosphate-activated enzyme with an optimal pH of 7·5, was observed in all parts of the kidney, though most of the activity was present either in the cortex or the papilla. The concentration of the enzyme in the inner medulla was conspicuous, since histological examination revealed only collecting and papillary ducts in these samples. It is therefore highly probable that enzymatic ammonia production occurs in this part of the nephron.

The total amount of papillary glutaminase I activity of the examined species was calculated by multiplying the weight of the inner medulla or papilla by the enzyme activity in a number of animals. As shown in Table 1 the total enzyme activity of this particular renal segment, containing exclusively collecting and papillary ducts, is sufficient to account for the maximal ammonia excretion observed in these species under acid stimulation. Various other correlations were tried, such as the total glutaminase I activity and the difference between glutaminase I activity and glutamine synthesis, but there was poor correlation with *in vivo* ammonia excretion.

It is well known that enzyme concentration is rarely a limiting factor for *in vivo* activity of biocatalytic systems; but, on the other hand, substrate or co-factor availability, intracellular pH and activators or inhibitors determine the rates of *in vitro* biochemical reactions[9]. Our observations seem to indicate that in ammonia excretion under maximal stimulation enzyme concentration may become limiting. This particular system offers the opportunity for the study of biocatalytic rate limitation by enzyme concentration.

These comparative enzymological and physiological studies suggest that enzymatic ammonia production for excretion in the mammalian kidney is a function of the collecting duct system. This was suggested by the micropuncture studies of Walker[10] in the frog, where the highest ammonia concentrations were found in the collecting ducts and ureters. Corroborative evidence is also supplied by clinical studies. Albright *et al.*[11] observed a patient with severe calcification of the renal pyramids who had deficient ammonia and acid secretion. The same metabolic defect was reported by Baines *et al.*[12] in a patient with extensive calcification of the pelvis and the pyramids but histologically intact tubular cells. Since hydrogen ion secretion is probably a function of the distal tubule[13], a separate anatomical localization of these two important mechanisms of acid secretion is highly probable and may explain th dissociation of these two tubular functions observed under certain pathological conditions. Oliveira[14] found a normal ammonia excretion but defective hydrogen-ion production in two patients with tubular necrosis. The same defect is frequently observed in the de Toni–Fanconi syndrome[15]. The opposite defect, normal acid excretion but impaired ammonia secretion, has been reported to occur in another renal disease of children with organic aciduria, hydrophthalmos, mental retardation and symptomatic rickets[16].

Catalase Production by Lactobacilli

Lactobacilli are considered to be catalase-negative[1], or occasionally to produce very small amounts of catalase[2]. The lactobacilli isolated from dairy products have always been found to be catalase-negative[3,4]. During recent work on the microflora of Cheddar cheese, we have encountered strains of lactobacilli which possess both strong and weak catalase activity. Three strains of *Lactobacillus plantarum*, originally isolated by Sherwood[3] from New Zealand Cheddar cheese, were found to be catalase-positive. Two of the strains gave strong catalase reactions whereas the other strain was much weaker (see Table 1). Serological[5] and physiological[6] tests have shown that these latter organisms are typical strains of *L. plantarum*.

Production of catalase was detected by streaking the cultures on to the following agar media: (1) tomato juice, dextrose of Briggs[7]; (2) lactose, yeast, phosphate of Hunter[8]; and (3) yeast, tryptone, glucose of Felton, Evans and Niven[9]. The plates were incubated anaerobically at 30° for two or three days, and then either flooded with 5 ml. of a 3 per cent hydrogen peroxide solution (10 vol.) or the growth was washed off with 0·5 ml. of sterile distilled water and 0·5 ml. peroxide added, and then observed for the appearance of oxygen evolution. The effect of composition of the medium upon the production of catalase by the three strains of *L. plantarum* is shown in Table 1.

Table 1. CATALASE PRODUCTION BY LACTOBACILLI ON DIFFERENT MEDIA

Strain No.	Medium 1 (2 per cent glucose)	Medium 2 (2 per cent lactose)	Medium 2 (0·5 per cent glucose)	Medium 3 (0 05 per cent glucose)
1 1	++	++	+++	+++
3 1	–	–	+	+
4·3	+	++	+++	+++
Control plates (uninoculated)	–	–	–	–
Staph. aureus *A* 227				++++

Catalase production was much increased when the strains were grown on a medium with a low glucose content, as Felton, Evans and Niven[9] found also with the *Pediococci*.

Staining Properties of the Golgi Zone of the Shell Gland of the Dogfish

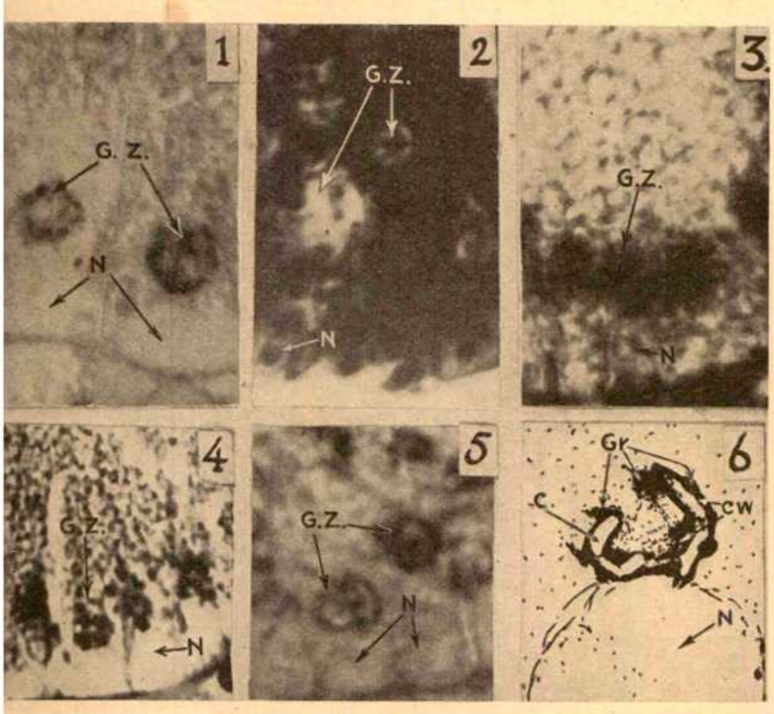
During research on the histochemistry of the shell gland of the dogfish, *Scyliorhinus caniculus*, some interesting reactions of the Golgi zone of the secretory cells have been observed.

In such material prepared according to Aoyama's silver technique, an oval or horse-shoe-shaped structure, either solid or with an argentophil exterior and an argentophobe interior, was visible in the Golgi zone (Fig. 1). In sections fixed in Regaud's fluid and afterwards postchromed, the secretory granules stained intensely with Heidenhain's hæmatoxylin, and an unstained circular or horse-shoe-shaped area was present in the Golgi zone above the nucleus (Fig. 2). Sections prepared in a similar manner and stained with sudan black showed a well-marked but diffuse zone without structural detail (Fig. 3).

In sections of the gland fixed in Bouin's fluid and stained with aniline blue (dilute, in 90 per cent alcohol) two diverse results were obtained. In some of the secretory cells a number of solid blue granules in size and appearance similar to the secretory granules contained within these cells, were localized in the Golgi region (Fig. 4). In other instances, however, such localized granules were absent, and in their place a diffuse zone similar to that shown by sudan black was clearly visible.

Finally, it was observed that gland tissue fixed in 70 per cent alcohol and afterwards stained with aniline blue in 90 per cent alcohol, after treatment with catechol[2], also demonstrated the presence of a

Golgi zone throughout the gland. This zone consisted of a circular or horse-shoe-shaped unstained canal (*c*, Fig. 6), with blue-stained walls (*c.w.*, Fig. 6), in contact with which were a number of dark blue granules (*g.r.*, Fig. 6).



(1), (2) and (5), × 1,200. (3) and (4), × 400. (6) Diagrammatic drawing of Golgi zone in Fig. 5.
G.Z., Golgi zone; *N*, nucleus; *c*, Golgi canal; *c.w.*, Golgi canal walls; *g.r.*, granules in contact with the Golgi canal walls

Of the above observations the most interesting is the constant staining, as opposed to metallic impregnation, of the Golgi zone with aniline blue, after treatment, either of whole tissues or sections, with catechol. That the resulting appearance of the Golgi region after such staining is identical with that revealed by the silver technique is surely not without significance, and lends support to the classical view of the morphology of this cell organoid. The constituent parts of the Golgi zone of these secretory cells, that is, the blue-stained walls bounding the unstained vacuoles, would appear to correspond respectively to the areas of double membranes and of vacuoles which have been shown by electron microscope studies to make up the Golgi region of other cells[1]. At present the action of the catechol in this technique is not understood; but it seems reasonable to assume that it acts on the protein part of the Golgi region, either as a mordant or by unmasking it so that it becomes 'stainable'.

Further research, with the object of standardizing this technique in its application to both invertebrate and vertebrate cells, is continuing, and it is hoped that the results will be published elsewhere.

I wish to thank Prof. R. A. R. Gresson for help and advice during this work.

A Toxic Lipid from the Surface of *Corynebacterium ovis*

WE have been studying the pathogenic properties of *Corynebacterium ovis*, a diphtheroid bacillus which causes the well-known and widespread disease of sheep known as caseous lymphadenitis. Natural infection takes the form of an initial suppurative inflammation of skin wounds. This is followed in about 20 per cent of cases by chronic metastatic abscesses in the regional lymph nodes. In most cases the infection in sheep does not progress any further; but occasionally *C. ovis* escapes from lymph node lesions to give rise to further abscess formation in lungs, spleen, liver and other visceral organs. The guinea pig is readily infected experimentally, but in contrast to the sheep is far less resistant to progressive extension of these pyogenic lesions and dies in eight to twelve weeks with abscesses in various internal organs.

When grown in liquid media, *C. ovis* produces an exotoxin possessing hæmolytic and lethal properties for the sheep, guinea pig and rabbit, the *LD*50 for guinea pigs of 250 gm. by subcutaneous injection being of the order of 0·1–0·005 ml. The exotoxin, or its formol-toxoid, is a good antigen, eliciting the production of a specific antitoxin which readily neutralizes toxin *in vivo* and *in vitro*.

In contrast with *C. diphtheriae*, in natural infection by *C. ovis* there is no evidence of acute intoxication, and antitoxin appears to play little or no part in protecting against infection. The great majority of experimental animals, both guinea pigs and sheep, in which high levels of antitoxin have been induced either actively or passively, are still readily infected with very small doses of live organisms (for example, 15 bacilli in guinea pigs by subcutaneous inoculation).

Phagocytosis of *C. ovis* by leucocytes of both sheep and guinea pigs occurs rapidly *in vivo* and *in vitro*. Leucocytes which have engulfed small numbers of *C. ovis* and are then maintained under tissue culture conditions undergo rapid degeneration and die.

In seeking the mechanism of this injurious action of engulfed organisms on leucocytes, we have found that a light extraction of live *C. ovis* with petrol ether removes a lipid without impairing the viability of the organism on ordinary culture media. This lipid extract is a wax-like substance with interesting toxic properties. It is insoluble in water; but when dissolved in either liquid paraffin or sterile guinea pig fat and injected intradermally in guinea pigs or rabbits, it produces a marked reaction characterized by swelling, congestion and, at the higher dose-rates, a central zone of hæmorrhagic necrosis which afterwards sloughs out. This reaction is not influenced by prior inoculation of the guinea pig with large doses of antitoxin, which specifically neutralizes exotoxin. We have also found that this lipid, dissolved in either liquid paraffin or sterile guinea pig fat, or absorbed on small particles of activated charcoal, when phagocyted by leucocytes, is followed by characteristic degenerative changes and death of the latter. On the other hand, doses of up to 500 mgm. of lipid in liquid paraffin inoculated intraperitoneally in guinea pigs produced no evidence of general systemic toxic effects.

There are obvious similarities between this toxic lipid of *C. ovis* and the surface lipoid component ('cord factor') of the virulent tubercle bacillus recently reported by Bloch and others[1], which, in addition to having toxic properties, appears to be closely concerned with the mechanism of the immunological response to the tubercle bacillus[2]. In contrast with the reported toxicity of 'cord factor', which produces death with pulmonary hæmorrhages in mice two to three weeks after intraperitoneal injection, *C. ovis* lipid has a local toxic action which appears within twenty-four hours after intradermal injection, leucocytes are especially vulnerable and no delayed systemic toxic effects have been observed in guinea pigs.

A detailed account of this work, including chemical and immunological studies at present in progress, will be published elsewhere.

Occurrence of New *Salmonella* Types from South Africa

UPON bacteriological examination of day-old chicks imported by air from the Union of South Africa and found dead on arrival at Elizabethville, the following types of *Salmonella* were detected by culturing the bone marrow of fourteen of them on the usual media: 2 strains of *S. saint paul* (4,5,12 : *e,h* : 1,2); 1 strain of *S. vejle* (3,10 : *e,h* : 1,2); 1 strain of *Salmonella* unidentified, probably *S. newport* (6,8 : *e,h* : 1,2) rough.

Salmonella saint paul and *S. vejle* seem never to have been isolated in South Africa[1-3]. A few strains of *S. newport* have been isolated by Henning[2], one from a human being and another from a duck.

In the Belgian Congo, *S. saint paul* has only been isolated from human stools (7 strains)[4]. *S. vejle* has been isolated only once from a native child's stools[4]. *S. newport* is well known and has been isolated several times from human material and from horse and goat[5-7].

In East Africa, between 1948 and 1953, Mackey[8] isolated in Dar es Salaam 3 strains of *S. saint paul*, all from human origin; none of *S. vejle* and 11 strains of *S. newport* (9 from humans and 2 from lizards).

We might thus consider that *S. saint paul* and *S. vejle* are new for South Africa.

This is also their first isolation from animals in the Belgian Congo, and the fact that they were found in imported chickens is one more hint on the complex epizootology of salmonellosis in animals.

We acknowledge with gratitude the co-operation of Dr. Joan Taylor, director of the Salmonella Reference Laboratory, Colindale Avenue, London, to whom all these strains were sent for identification.

Influence of Nutritional State on the Heat Tolerance of Cattle

ON completion of an experiment in which two differently fed groups of cattle were used for studying the effect of low nutrition on seasonal changes in the hair coat, opportunity was also taken to make observations on the heat tolerance of the animals. The results of these latter observations are reported here.

On April 20, 1955, eight poll shorthorn heifers aged 6–8 months and weighing an average of 351 lb. were randomly divided into two groups of four animals each. One group, kept on clean straw bedding, was fed liberally, calf meal (18 per cent crude protein) being supplied at the rate of 2 lb. per animal per day together with as much lucerne hay as the animals would consume. On this ration, individuals of the group increased to an average of 672 lb. weight by February 28, 1956. The feed of the other group was restricted as necessary to maintain constant weight of the individuals over the same period. They were bedded on sawdust and received meal at the rate of 4 oz. per animal per day, one-quarter the amount of lucerne hay supplied to the well-fed group and less straw than sufficient to satisfy appetite. Both groups received vitamin supplement in the form of a commercial preparation of fish liver oil.

On February 28, 1956, immediately following their usual morning feed, the eight heifers were subjected to a heat tolerance test in a psychometric room. The duration of the test was three hours unless an animal's rectal temperature reached 107° F., in which case the individual was withdrawn. The room temperature during exposure was 105° F. dry bulb and 92° F. wet bulb. Rectal temperatures were taken at the end of each hour, and each animal's heat tolerance coefficient was calculated from its rectal temperature at the end of the test, using Rhoad's[1] formula:

$$\text{Heat tol. coeff.} = 100 - 10\,(\text{rect. temp.} - 101)$$

The mean heat tolerance coefficient of the fat, well-fed group was 43; that of the thin, poorly fed group 55. The difference of 12 between the group means is highly significant ($P = 0{\cdot}01$) and reflects the greater heat tolerance of the thin animals. This was also evidenced by their relative freedom from drooling, their calmer breathing and less anxious state at the end of the test.

Following this test, the poorly fed group was placed on the liberal ration, whereas no feed at all was allowed the well-nourished group. These feeding conditions obtained for the post-test period of February 28, for all of February 29 and for the morning of

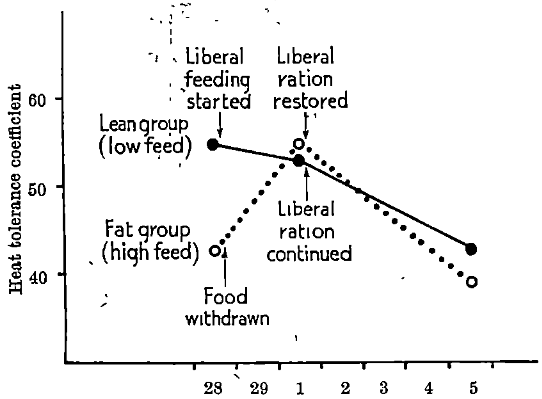

Fig. 1. Influence of the current rate of feeding on the heat tolerance of two groups of cattle reared on different planes of nutrition

arch 1, when the heat-tolerance test was repeated. his time the heat tolerance of both groups was good nd the difference between the mean of the fat group 55) and the mean of the thin group (53) was not tatistically significant. The notable result was the 2-point improvement in heat tolerance of the fat nimals.

After this test, both groups were placed on the iberal ration until a third heat-tolerance test was onducted four days later, on March 5. This time oth groups showed poor heat tolerance. The mean eat-tolerance coefficients were 39 and 43 for the fat nd thin groups, respectively, the difference not being tatistically significant.

The results, presented graphically in Fig. 1, show hat high condition is not in itself a disadvantage to attle in withstanding heat. A high current rate of eeding, however, in either fat or poor cattle may, nder hot conditions, add seriously to the heat load f the animals. This is similar to the conclusion eached for hens, sheep and pigs by Robinson and ee[2], who also reported that the proportion of protein ontained in the diet was without effect on the heat olerance of these three species.

The present experiment also showed that, following hange to the liberal ration, the heat tolerance of the nder-nourished animals was still high two days after he change, but was low by the sixth day. The lag s probably a reflexion of the time required for the igestive tract of cattle to condition itself to assimilating and utilizing more and better feed, following long period of restriction.

These results emphasize, *inter alia*, the importance f standard feeding routine when seasonal or other eriodic heat tolerance tests are to be made.

The environmental studies of which this experiment orms a part are being conducted at the Physiology epartment, University of Queensland, and, as an fficer of the Division of Animal Health and Production, Commonwealth Scientific and Industrial esearch Organization, I am grateful to Prof. W. V. Macfarlane for his co-operation and help.

Identification of *Pseudomonas pyocyanea* by the Oxidase Reaction

Although the identification of *Pseudomonas pyocyanea* is generally very simple, the diagnosis of 'atypical' strains may take several days, and, as Schaub and Foley[1] stress, "its identification may present a problem". Yow and Townsend[2], in their study on the sensitivity of *Ps. pyocyanea* to various antibiotics, limit the scope of their examinations: "Because of the difficulty in positively identifying the non-pigment-producing strains of Pseudomonas, only those producing either pyocyanin, fluorescin, or both, were included in this study". However, apyocyanogenic strains are common. These strains are either primarily deficient in producing pigment or may have lost their ability to do so. Haynes[3] therefore points out: "Strains not producing pyocyanin, from whatever source, cannot be dismissed from consideration as Ps. pyocyanea."

Already Gordon and McLeod[4] have observed that *Ps. pyocyanea*, besides other bacteria, gives a positive oxidase reaction although much less markedly than the Neisserias.

I have increased the sensitivity of the oxidase reaction by the following technique. A piece of Whatman's No. 1 filter paper, about 6 cm. square, is laid in a Petri dish. Two to three drops of 1 per cent tetramethyl*para*phenylenediamine dihydrochloride solution is dropped on the centre of the paper. The suspect colony is removed with a platinum rod and is smeared thoroughly on to the reagent-impregnated filter paper in a line 3–6 mm. long. If the reaction is positive, the transferred colony turns dark purple in 5–10 sec. The reagent should be prepared every two weeks and kept in a dark, glass-stoppered dropping bottle in the refrigerator.

All 436 *Ps. pyocyanea* strains examined gave a positive oxidase reaction with the technique described, while the other common Gram-negative rods are oxidase negative. The oxidase reaction can be used as a simple, rapid screening test in the diagnosis of *Ps. pyocyanea*.

Detailed investigations on the confirmatory test for *Ps. pyocyanea* will be published elsewhere.

Structure of the Ascidian *Octacnemus* Moseley

The tunicate family Octacnemidae contains two genera, *Octacnemus* Moseley and *Polyoctacnemus* Ihle, and four species, all from great oceanic depths. The species have been described by Moseley[1], Herdman[2], Metcalf[3], Ritter[4], and Madsen[5]; but their structure is peculiar and has never been satisfactorily related to that of other tunicates.

Octacnemus, the better-known genus, has in particular the following characters not found in other tunicates: (1) a crown of eight large triangular lobes on the upper side, (2) an upper and a lower cavity between the test and the body proper, (3) a 'horizontal membrane' separating these two cavities and extending out into the eight lobes. The organs of the body are less peculiar; but the pharynx is much modified, having only a few imperforate branchial stigmata or none at all. The nature of the crown of lobes has never been satisfactorily explained, and the upper and lower cavities between the test and the body have generally been taken to represent the expanded cavity of the oral siphon and the modified atrial cavity respectively (Ihle[6], Madsen[5], Brien[7]). Ritter[4], however, maintained that at least the upper cavity is an artefact.

I have recently been able to examine a single specimen of *Octacnemus bythius* Moseley, taken in 1952 by the Danish Deep Sea Expedition from 2,700 metres in the Kermadec Deep. The specimen showed the well-known features of the species; but dissection revealed the presence of a true atrial cavity agreeing in position with that of unmodified ascidians—that is, dorsal to the pharynx—although in *Octacnemus* it is too small to envelop the sides of the pharynx. The partition between the atrial cavity and the pharynx is perforated by a few small openings, but it is uncertain if these represent modified branchial stigmata. There is a short tubular atrial siphon, the outer end of which has been torn away from the test. The atrial siphon is evidently the structure described and illustrated by Moseley as the rectum; the true rectum opens within the base of the atrial siphon as in other ascidians.

The crown of eight lobes and the corresponding prolongations of the 'horizontal membrane' represent, with little doubt, the greatly developed lobes of the oral siphon. The position of the lobes around the opening to the pharynx, their number, the relation of their circular and longitudinal muscles, and the presence of test on both faces of the lobes all point to this conclusion. The 'horizontal membrane' is simply the expanded and opened-out base of the oral siphon.

The Octacnemidae are therefore true, although much modified, ascidians, since the crown and 'horizontal membrane' are the enlarged oral siphon, a true atrial cavity and atrial siphon exist, and the upper and lower cavities between test and body may be artefacts produced at death. The number of oral lobes and the arrangement of the gonads indicate that the family belongs to the sub-class Enterogona, probably having been evolved from an ancestral form rather like *Ciona*.

A fuller account of this work is being published elsewhere.

Hand-rearing of Rabbits

Rabbits that were completely free of coccidia infection were desired for experimental purposes. It appeared to be impossible to obtain such rabbits by normal breeding methods, as infection, usually very mild, occurred during contact with the doe in the nest. It was therefore decided to try to hand-rear rabbits which had been removed from the doe at birth.

The expression of milk from the doe was found to be impractical, so cow's milk was used. The protein content of rabbit milk is approximately 10 per cent, whereas that of the cow is 4 per cent, and therefore in order to increase the protein, calcium caseinate was added at the level of 15 gm. to 10 oz. of cow's milk. After several attempts it was found that this mixture could be used until the animals were seven days old, when it was necessary to increase the amount of calcium caseinate to 17 gm. for 10 oz. cow's milk and at fourteen days old the level of calcium caseinate was further increased to 20 gm. This level was maintained until the young rabbits were able to eat fresh green food when about four weeks old, at which time they were weaned. Fig. 1 shows the weight curves for the hand-reared animals and their litter mates still with the doe.

The calcium caseinate did not dissolve freely in the cow's milk unless the whole was beaten with an egg whisk. This mixture would keep for several days in a refrigerator. The milk mixture was warmed by placing it in the feeding bottles and immersing them in a cup containing warm water.

As delivery of the milk was not satisfactory with a pipette, feeding bottles with rubber teats as used for dolls were obtained. After making a hole in the end of the teat, the only difficulty encountered was the over-anxiousness of the young rabbit to obtain its milk; and a little practice was necessary in order to insert the teat satisfactorily between the tongue and upper jaw of the animal. The rapidity with which the milk was consumed did not appear to affect the animal adversely. Sufficient was judged to have been given when the rabbit would take no more, despite a rest of a few minutes.

The feeds were given approximately every three hours, the last feed being at midnight and the first

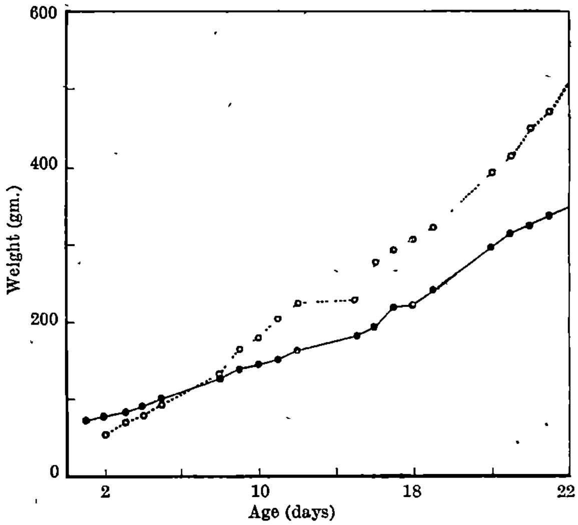

Fig. 1. ●—●—, Hand-reared; ○ -- ○--, naturally reared

at 5–6 a.m. The animals were transported in a box ined with hay and cotton-wool and care was taken o ensure that they were at all times kept warm.

One danger that was met was the accidental nhalation of some of the milk, which caused a fatal pneumonia. Another hazard was an enteritis which was successfully treated with intramuscular injections of chloramphenicol.

Insecticide Resistance in *Anopheles gambiae* Giles

THE appearance of *Anopheles gambiae* resistant to dieldrin only eighteen months after this insecticide was first used in a malaria control pilot project in Northern Nigeria has recently been reported[1]. It was calculated to be some eight times as resistant as a susceptible strain of the same species maintained at the Ross Institute of Tropical Hygiene, London[2].

Through the courtesy of Dr. L. J. Bruce-Chwatt, malariologist, Government of Nigeria, eggs of the esistant *A. gambiae* were dispatched to the Ross nstitute, and this strain has now been successfully olonized. This successful dispatch of viable eggs from such an out-of-the-way part of Africa was in tself a major achievement. Colonization proved a elatively simple matter, in fact much more simple than the colonization of a susceptible strain of the ame species from Lagos. This latter colony was tarted in 1951 and has been maintained in London ver since[3].

The two strains of the same species have now been ompared for their susceptibilities to a range of nsecticides using the technique described by Busvine n an annex to the Fifth Report of the World Health Organization Expert Committee on Malaria[4]. This echnique involves the exposure of mosquitoes to lter paper impregnated with various concentrations f insecticides in Risella oil for 1 hr. and recording mortalities 24 hr. later. Table 1 records the median lethal concentrations of various insecticides after this -hr. exposure. The resistant strain was so highly esistant to dieldrin and aldrin that even 4 per cent olutions of these insecticides (a percentage nearing aturation in the case of dieldrin) failed to give any kill after exposure for 1 hr. This strain was, however, usceptible to DDT, pyrethrins and malathion. The slight difference in median lethal concentration of the two latter insecticides for the two strains is thought merely to be a reflexion of the difference in size and vigour generally of the resistant strain. The Northern Nigeria strain was some twenty-six times as resistant to gamma-BHC as the Lagos strain.

able 1. Median lethal concentrations (percentages in Risella oil or live oil) of various insecticides when susceptible and resistant strains f *Anopheles gambiae* are exposed for one hour. (Numbers of female mosquitoes tested at concentrations giving more than 0 and less than 100 per cent mortalities are given in brackets)

Insecticide	Lagos strain (susceptible)	Ambursa strain (resistant)
Pyrethrins	0·4 (138)	0·8 (302)
DDT	0·6 (201)	0·6 (97)
Malathion*	0 8 (60)	1·4 (50)
Gamma-BHC	0·007 (177)	0·18 (62)
Dieldrin	0·08 (831)	no kill at 4 per cent
Aldrin	0 2 (142)	no kill at 4 per cent

* In solution in olive oil.

Table 2. Percentage mortalities among susceptible and resistant *Anopheles gambiae* exposed for 5 hr. to various concentrations of insecticides. (Numbers of female mosquitoes tested are given in brackets)

Percentage concentration of insecticide in Risella oil	Dieldrin	Aldrin	Isodrin	Endrin	Alpha-chlordane	Beta-chlordane
	Susceptible strain					
0 001	4 (50)	6 (38)				
0 01	81 (52)	15 (35)	32 (63)	14 (43)		
0 05			64 (47)	64 (44)		
Check	5 (20)	0 (18)	8 (39)	8 (39)		
	Resistant strain					
2 0			11 (19)	5 (21)		
4 0	10 (70)	2 (57)	65 (82)	76 (80)	0 (21)	
5 0						0 (22)
8·0			79 (42)			
10·0					0 (20)	
Check	0 (46)	0 (18)	3 (76)	3 (76)	0 (24)	0 (24)

To ascertain the degree of resistance to other insecticides, the exposure time had to be increased, and this necessitated decreases in concentrations for the susceptible strain. Table 2 summarizes mortalities 24 hr. after 5-hr. exposures to dieldrin, aldrin, isodrin, endrin, alpha-chlordane and beta-chlordane and shows the resistant strain to be some 140 times as resistant to isodrin and some 90 times to endrin as the Lagos strain. These results also show the resistant strain to be at least 400 times as resistant to dieldrin; but kills with the other three insecticides were still too small to indicate the degrees of resistance.

Exposures of 18 hr. were then resorted to, but this brought in the complication of check mortalities; these were eventually reduced to almost zero by exposing the mosquitoes in open-ended tubes, the ends being covered with mosquito netting. Table 3 compares the mortalities after 18-hr. exposures of the susceptible and resistant strains to dieldrin, aldrin, alpha-chlordane and beta-chlordane. The resistant strain is some 800 times as resistant to dieldrin and some 400 times to aldrin. Kills were again too low with alpha- and beta-chlordane to assess the degrees of resistance, which must be more than 1,000 in the case of alpha- and more than 500 in the case of beta-chlordane.

These results show a remarkably high degree of resistance to dieldrin and related compounds in the Northern Nigeria strain, a degree much higher than that recorded on the spot[1]. It is suggested that in the

Table 3. Percentage mortalities among susceptible and resistant *Anopheles gambiae* exposed for 18 hr. to various concentrations of insecticides. (Numbers of female mosquitoes tested are given in brackets)

Percentage concentration of insecticide in Risella oil	Dieldrin	Aldrin	Alpha-chlordane	Beta-chlordane
	Susceptible strain			
0·001	24 (104)	14 (59)	37 (59)	24 (82)
0 005	65 (61)			
0·01	98 (63)	24 (25)	40 (62)	55 (84)
Check	3 (93)	1 (72)	7 (68)	7 (88)
	Resistant strain			
4·0	70 (140)	24 (131)	0 (21)	
5·0				8 (131)
10·0			19 (119)	
Check	7 (97)	7 (98)	7 (122)	7 (122)

susceptibility tests made in Nigeria itself a mixed population of susceptible and resistant mosquitoes was used. This is borne out by the fact that significant kills were produced by an exposure of only 1 hr. to dosages of dieldrin considerably less than 4 per cent, even as low as 0·5 per cent. The eggs sent on three separate occasions to London may also have been mixed susceptible and resistant strains; but only a small percentage survived the journey. It is suggested that these were the highly resistant individuals; in other words, the journey by air has resulted in a selection of only the most vigorous mosquitoes, which are at the same time the ones highly resistant to insecticides.

Cross-resistance to the related chlorinated hydrocarbons, aldrin, alpha- and beta-chlordane, isodrin, endrin and gamma-BHC, has previously been commented on by Busvine[5] and Metcalf[6]. Busvine places these insecticides in the following order from the degrees of resistance shown by houseflies: alpha-chlordane (highest), beta-chlordane, aldrin, dieldrin, gamma-BHC, isodrin and endrin (lowest). With the resistant *A. gambiae* the order would appear to be: alpha-chlordane (highest), beta-chlordane, dieldrin, aldrin, isodrin, endrin and gamma-BHC (lowest).

A High Frequency of Heterozygous Diploids and Somatic Recombination produced by Ultra-violet Light in Imperfect Fungi

PONTECORVO and his co-workers[1] have demonstrated that, by the use of appropriate selection techniques, heterozygous diploids can be secured from heterocaryons of *Aspergillus nidulans*. Further, these diploids produced, on cultivation, recombinants by both somatic crossing-over[2] and somatic reduction. Later, similar results were obtained with the asexual strains, *Aspergillus niger*[3] and *Penicillium chrysogenum*[4]. I have succeeded in producing heterozygous diploids in the asexual fungi *A. sojae* and *A. oryzae* by the use of similar methods. These diploids also showed somatic segregation and yielded recombinations of the original genotypes. First-order segregations showed further segregation upon cultivation. Only a few segregants have been analysed and all proved to be still diploid in having double the haploid amount of deoxyribonucleic acid per nucleus. Their occurrence can be explained by the same type of somatic crossing-over as that discussed by Pontecorvo[5] and originally discovered by Stern[6].

The frequency of spontaneously arising somatic diploid nuclei in *A. sojae* is about 10^{-7}, or the same as that in *A. niger* and *A. nidulans*. In all three fungi, camphor increased this frequency to about 10^{-6}. It was further found that the frequency of heterozygous diploids in *A. sojae* could be raised to more than 10^{-2} by ultra-violet light.

When conidia of a heterocaryon between yellow-leucineless and albino-histidineless mutants of *A. sojae* were exposed to ultra-violet light until only about 1 per cent survived and were then plated on complete medium, 2–9 per cent of the survivors formed green colonies which were also prototrophic and diploid. Similar results were obtained with other heterocaryons and with one between yellow-methionineless and albino-leucineless mutants of *A. oryzae*. This great increase in diploidization was not simply due to the selective survival of diploid nuclei which were spontaneously present, as the relation between a survival of 10^{-2} and the increase from 10^{-7} to 10^{-2} in the frequency of diploids clearly shows; there was an absolute increase in the numbers of diploids.

Ultra-violet light was also active in stimulating somatic segregation in these diploids. When conidia from a green diploid colony were irradiated with different doses, there was a progressive decrease, from 9 to 75 per cent, in the green colonies formed upon plating. Correspondingly, there was an increase in the frequency of albino, yellow and sectored segregants. This phenomenon may be similar to that observed by James[7] with heterozygous diploid yeast.

The use of ultra-violet light to produce an extraordinarily high frequency of heterozygous diploids in asexual fungi should make feasible an analysis of their mode of origin and their subsequent behaviour and should also greatly facilitate the production of new and improved strains for industrial use.

The results of this investigation will be published in detail and in English in the *Journal of General and Applied Microbiology*.

"Polyploidy in Bluebells"

J. YANNEY WILSON has recently given an account of polyploidy in bluebells (*Endymion non-scriptus* and *E. hispanicus*)[1]. There are some errors in this paper which it is desirable to correct. The "extraordinarily large forms" to which reference is made have not been determined by me as hybrids. Apparently the author has misunderstood the excellent coloured figures in the *Botanical Magazine*, N.S., 176 (1952). The central figure is of *Endymion hispanicus* the left-hand one is of *E. non-scriptus*, and the right-hand one is of the putative hybrid. Further, the impression is given that Mr. Yanney Wilson examined my material cytologically; but he has not done so and I have not had the opportunity of studying his plants taxonomically.

W. B. TURRILL

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, October 1

Society of Engineers (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. K. J. Frost: "The Calder Hall Nuclear Power Station".

Tuesday, October 2

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. J. Harris: "Prestressed Concrete Runways: History, Practice and Theory".

Tuesday, October 2—Thursday, October 4

Department of Scientific and Industrial Research, Chemical Research Laboratory (at Teddington, Middlesex)—Open Days

Tuesday, October 2—Wednesday, October 10

Fuel Efficiency Exhibition (at Olympia, London, W.14).*

Wednesday, October 3

Technical Meetings to discuss "The Efficient Use of Fuel in Industry". (Further meetings on October 4, 9, and 10.)

Wednesday, October 3

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. J. B. Capdeville: "The Le Havre–Paris Pipeline".

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "Chromatography". Mr. W. H. C. Shaw, Mr. J. P. Jefferies and Mr. T. E. Holt. "The Determination of Vitamin D and Related Compounds. Part I: Introduction and Preparation of Compounds in the Irradiation Series. Part II: Analysis of Irradiation Products"; Dr. A. S. Curry: "Some Examples of the Use of Paper Chromatography in Toxicological Analysis".

Thursday, October 4

Bone and Tooth Society (at the Institute of Orthopædics, 234 Great Portland Street, London, W.1), at 5 p.m.—Symposium on "Tissue Culture and the Induction of Bone and Connective Tissues". Prof. J. J. Pritchard: "Bone and Cartilage Induction in the Rabbit, Rat and Guinea Pig"; Lady May Mellanby and Mr. P. J. Holloway: "Tissue Culture as a Tool in Dental Research"; Dr. J. D. Biggers: "Studies in the Cultivation of Embryonic Bones in Chemically Defined Media"; Mrs. Shirley Hughes: "Experimental Embryology of Teeth".

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Prof. W. R. Jones: "Mineral Resources". (First of a series of six lectures on "The Conservation of Natural Resources.")

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Sir Gordon Radley: Inaugural Address as President.

Friday, October 5

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Sir Charles Dodds, F.R.S: "Application of Chemical Analysis to Medical Diagnosis and Treatment". (Chairman's Address.)

Society of Chemical Industry, Fine Chemicals Group (joint meeting with the Microbiology Group, at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 7 p.m.—Prof. A. Neuberger, F.R.S.: "Some Uses of Isotopes in Biochemistry".

Saturday, October 6

Association of Clinical Biochemists (joint meeting with the Association of Clinical Pathologists, at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 9.30 a.m.—Scientific Papers and a Symposium on "Biochemical Lesions: Keto-Acid Metabolism and the Citric Acid Cycle".

Nutrition Society, and Laboratory Animals Bureau (at Guy's Hospital Medical School, St. Thomas Street, London, S.E.1), at 10.40 a.m.—Joint Symposium on "The Nutrition of Laboratory Animals".

British Interplanetary Society (in the York Hall, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Prof. H. S. W. Massey, F.R.S: "The Study of the High Atmosphere in the International Geophysical Year".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade B (with an honours degree in chemistry, and preferably experience in industry, teaching or research), to teach organic and inorganic chemistry—The Principal, Wigan and District Mining and Technical College, Wigan (October 5).

Senior Lecturer in Radiology at University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (October 5).

Assistant Lecturer (medically qualified) in the Department of Physiology—The Registrar, The University, Liverpool (October 6).

Chair of Agriculture in the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 9).

Lecturer or Assistant Lecturer in Physics—The Registrar, The University, Hull (October 13)

Assistant Lecturer in Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (October 15)

Lecturer in Mechanical Engineering Design—The Secretary of University Court, The University, Glasgow (October 17).

Assistant Lecturer (with special interests in the field of historical geography) in Geography—The Registrar, University College, Singleton Park, Swansea (October 20).

Lecturer in (*a*) Physical Geography and (*b*) Economic Geography at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 20).

Lecturer in Pure Mathematics—The Secretary, Queen's University, Belfast (October 20).

Lecturer (with a degree or diploma or equivalent qualifications, and preferably previous lecturing experience) in Zoology at the New South Wales University of Technology, Sydney, Australia—The Agent-General for New South Wales, 56 Strand, London, W.C.2; and The Bursar, New South Wales University of Technology, Box 1, Post Office, Kensington, N.S.W., Australia, marking envelope "University Appointment" (October 26).

Lecturer/Senior Lecturer in Applied Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 2[illegible]).

Chair of Education in the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturer in Physical Metallurgy at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, October 31).

Lecturer or Assistant Lecturer in Geology at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

Senior Lecturer (with a degree in engineering and practical experience in applied hydraulic work) in Civil Engineering (Hydraulics) at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Senior Lecturer (with a degree in veterinary medicine or an honours degree in science or agricultural science) in Animal Husbandry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

University Demonstrator in Biochemistry—Prof. H. A. Krebs, Department of Biochemistry, South Parks Road, Oxford (October 31).

Biologist (with a recognized university degree, with honours, or equivalent qualification, for which an adequate study of biology or zoology was necessary)—The Secretary, The Salmon Research Trust of Ireland Incorporated, St. James's Gate, Dublin (November 1).

Nuclear Technologist (with an honours degree in physics or engineering, and experience in nuclear engineering, reactor technology, and instrumentation) at the Central Electricity Authorities' Research Laboratories at Leatherhead, to deal with problems likely to arise in the operation of reactors in nuclear power stations—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. E./884 (November 12).

Chair of Physics in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

Biochemist (with a first- or second-class honours degree in biochemistry or equivalent qualification, and postgraduate research experience) to study the chemical properties of cervical mucus in relation to the action of sex hormones—The Secretary, National Institute for Research in Dairying, Shinfield, Reading.

Biochemist (with a good honours degree in biochemistry) at the Government Tea Research Station, Mlanje, to conduct research on the fermentation of tea—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD 63/4/018.

Botanist (with at least a second-class honours degree in botany) to undertake taxonomic botanical work at Kew and the British Museum (Natural History) and possibly periods of field work in Africa, in connexion with the preparation of a Flora of Rhodesia—The Director of Recruitment, Colonial Office, London, S.W.1, quoting RES.134/1/02.

Chief Research Chemist (with a Ph.D. degree in biochemistry and some successful experience in an organized research programme) in the Saskatchewan Department of Public Health, to supervise the biochemical aspects of psychiatric research in Saskatchewan—The Public Service Commission, Legislative Building, Regina, Saskatchewan, quoting Ref. No. 4356.

Chief Technician or Senior Technician to take charge of Hydrogen Liquefaction Plant—The Steward, Physics Department. The University, Edgbaston, Birmingham 15.

Cyclotron Engineer or Physicist (graduate in light electrical engineering)—The Senior Cyclotron Engineer, Medical Research Council, Hammersmith Hospital, Ducane Road, London, W.12.

Head (graduate of a British university and good experience in teaching and in industry) of the Department of Electrical Engineering and Physics—Clerk to the Governing Body, Borough Polytechnic, Borough Road, London, S.E.1.

Head of the Microbiology Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Lecturer (science graduate, preferably in microbiology, and with experience in dairy technology)—The Principal, National College of Food Technology, Cranwood Street, City Road, London, E.C.1.

LECTURERS (with an engineering or science degree, preferably lecturing experience, and a specialist knowledge of either electrical engineering or electronics, or servo-mechanisms) AT THE R.E.M.E. TRAINING CENTRE, Arborfield—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.387/6A.

PALÆONTOLOGIST (with a first- or good second-class honours degree in geology and at least six years postgraduate work in palæontology, and a fair knowledge of micropalæontology) with the Government of Cyprus Geological Survey, to identify fossils and microfauna in order to determine the age of sedimentary formations, and to assist in the mapping of fossiliferous formations—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/17/03.

RADIATION CHEMIST (with a Ph.D. or equivalent qualifications, and several years experience in the radiation chemistry of aqueous systems and solution reaction kinetics) in the Defence Research Chemical Laboratories, Ottawa, Canada—Defence Research Member, Canadian Joint Staff, Moncorvo House, 66 Ennismore Gardens, London, S.W.7.

RESEARCH ASSISTANT (graduate in biochemistry or chemistry) IN THE DEPARTMENT OF CLINICAL PATHOLOGY—The Administrator and Secretary, University College Hospital, Gower Street, London, W.C.1.

SENIOR RESEARCH ASSISTANT (with a good honours degree in metallurgy or physics, practical experience and/or research training) IN THE FACULTY OF APPLIED SCIENCE, to work in the field of creep and fatigue of ferrous materials—The Registrar, The University, Nottingham.

TECHNICAL OFFICER (with good practical experience, and preferably a degree or diploma in agriculture) FOR CEREAL MULTIPLICATION—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

LECTURES AND COURSES

NORTHAMPTON POLYTECHNIC

ST. JOHN STREET, LONDON, E C.1

A Course of Twenty-two Lectures on
AN INTRODUCTION TO NUCLEAR POWER
will be given on
Monday evenings at 7 p m. commencing
Monday, October 8, 1956,
by a panel of specialists

The fee for the course is 40s.

Application for enrolment should be made to the Secretary

OFFICIAL APPOINTMENTS

NORTH LINDSEY TECHNICAL COLLEGE

KINGSWAY, SCUNTHORPE, LINCS
Principal: F. C. Jones, B.Sc (Eng),
A.M.I.Mech E., A.M.I E.E.

Applications are invited for the following appointments. (a) Fitter-Turner for general machining and fitting in connection with the manufacture and maintenance of a wide range of apparatus and equipment. The appointment offers interesting work with good conditions to the right type of applicant. A good apprenticeship and possession of a City and Guilds Intermediate Certificate in Machine Shop Engineering would be useful recommendations. Salary £9 14s. 4d. per 44 hour week. Duties to commence as early as possible. (b) Laboratory Steward for general laboratory duties in the Engineering and Building Departments Previous experience in the preparation and maintenance of this type of apparatus and equipment is essential. Possession of a national certificate or City and Guilds Certificate in an appropriate subject would be a recommendation. Salary and conditions in accordance with Miscellaneous, Div. III of N.J.C. Scale, i e., £445 rising to £510 per annum, by three increments of £15 and one of £20. Duties to commence as early as possible.

Apply by letter to the Principal at the above address as early as possible, giving full details of age, experience, and qualifications, copies of two recent testimonials, and the names of two persons for confidential reference.

AUSTRALIAN NATIONAL UNIVERSITY

GENERAL MOTORS-HOLDEN'S FELLOWSHIPS

Through the generous foundation of General Motors-Holden's the University is enabled to invite applications for study in Canberra from university graduates. Three awards are offered, each tenable for one year, commencing in 1957 In the discretion of the University these awards may be made with the expectation of renewal for a further period not exceeding two years. Preference in selection will be given to students preparing for careers in industry, or for academic careers, including teaching, and who have graduated in disciplines related to the sciences, engineering, commerce, or economics The value of the Fellowships, which will not be less than £A.800 per annum nor more than £A 1,200 per annum, will be determined according to the needs and seniority of the applicant These emoluments will be exempt from Australian income tax. Those to whom Fellowships are awarded will be required to take up their Fellowships at the beginning of the 1957 academic year (March) Applicants must be university graduates with some research experience. Successful applicants may be able to enrol for a degree (Ph D., M.A., or M Sc.).

Further particulars and application forms should be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on October 15, 1956

UNIVERSITY OF GLASGOW

ASSISTANTSHIP IN ZOOLOGY

Applications are invited for an Assistantship in Zoology Salary scale £550 to £650. Initial salary according to experience and qualifications. F S S.U. and family allowance benefits Special interest in vertebrates an advantage, although not indispensable

Applications (three copies) should be lodged not later than October 5, 1956, with the undersigned, from whom further particulars may be obtained

ROBT. T HUTCHESON,
Secretary of University Court.

CHESTER BEATTY RESEARCH INSTITUTE

INSTITUTE OF CANCER RESEARCH
ROYAL CANCER HOSPITAL

Technician (female) required to assist in biological research at the Pollards Wood Research Station of the Institute of Cancer Research: Royal Cancer Hospital, at Chalfont St. Giles, Buckinghamshire. Previous experience in cytological or histological techniques is desirable. The post is superannuable and the salary is on a scale in accordance with age and qualifications —Applications, marked "OGF," should be sent to the Secretary, Chester Beatty Research Institute, Fulham Road, London, S.W 3, within a week of the appearance of this advertisement

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

A vacancy exists for a Biochemist to study the chemical properties of cervical mucus in relation to the action of sex hormones, initially for a period of one year, with probable extension Commencing salary up to £1,100, according to qualifications and experience. Candidates should possess first- or second-class honours degree in biochemistry, or equivalent qualification, with postgraduate research experience.

Applications, with names of two referees, to the Secretary, N.I.R D., Shinfield, Reading. Quote reference 56/3

RADIATION CHEMIST

Defence Research Board

CANADA

A Radiation Chemist with a Ph.D. or equivalent and several years' experience in radiation chemistry of aqueous systems and solution reaction kinetics is required for work in these fields. The position is with the Defence Research Chemical Laboratories, Ottawa, Canada. Initial salary will be in the range $6,000 to $7,300, depending on qualifications and experience. There is generous provision for vacation and sick leave, pension and medical-hospital insurance plans. Candidates must be Canadian citizens or British subjects.

Apply to:
Defence Research Member,
Canadian Joint Staff,
Moncorvo House,
66 Ennismore Gardens,
London, S.W.7, England.

SHEFFIELD REGIONAL HOSPITAL BOARD

SHEFFIELD NO. 4 HOSPITAL MANAGEMENT COMMITTEE
RADIOTHERAPY CENTRE
ASSISTANT PHYSICIST

Applications are invited for a post as Assistant Physicist (basic grade) in the Physics Department of the Sheffield National Centre for Radiotherapy. Candidates should have a good honours degree in physics Experience in hospital physics is not essential but experience in electronic and nuclear physics techniques will be an advantage. The successful candidate will assist in the development and research work of the Centre. Salary according to Whitley Council Scales For first- and second-class honours £525 by £25 to £625 (others £475 by £25 to £575) for probationary period Subsequent salary in basic grade £650 by £30 to £740 by £35 to £845 Starting salary will depend on postgraduate experience.

Applications, with names of at least two referees, should be sent to the Secretary, "Broom Cross," Tree Root Walk, Sheffield, 10, and should reach him within twenty-one days of the appearance of this advertisement. Further particulars of the post may be obtained on application to the Secretary

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to a post of Lecturer in Physical Metallurgy on the staff of the University's Department of Metallurgy. The salary attached to the post will be on the scale £850 by £50 to £1,150 per annum, plus a cost-of-living allowance at the rate of £234 per annum in the case of a married man. Membership of the Provident Fund is compulsory and involves a contribution at the rate of 7 per cent of the salary paid. Membership of the Staff Medical Aid Fund is obligatory in the case of an officer who is found eligible for membership.

Applicants are advised to obtain further information regarding this vacancy from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in South Africa and London on October 31, 1956

NOTTINGHAM NO. 1 HOSPITAL MANAGEMENT COMMITTEE

Applications are invited for a post as Assistant Physicist (Basic Grade) in the Physics Department of the Hogarth Radiotherapeutic Centre at the General Hospital, Nottingham Candidates should have a good honours degree in physics. Experience in hospital physics is not essential, but experience in electronics would be an advantage Work in the Centre includes radioactive isotopes, deep, superficial and rotation therapy and radium and radon treatment. Salary according to Whitley Council scales. For first- and second-class honours £525 by £25 to £625 (others £475 by £25 to £575) for probationary period Subsequent salary in basic grade £650 by £30 to £740 by £35 to £845. Starting salary will depend on postgraduate experience

Applications, with names of at least two referees and details of qualifications and experience, should be sent to the Group Secretary, Nottingham No. 1 Hospital Management Committee, General Hospital, Nottingham.

CENTRAL ELECTRICITY AUTHORITY Research Laboratories, Leatherhead, require a Nuclear Technologist to deal with problems likely to arise in the operation of reactors in nuclear power stations. Opportunity exists for building up the work on reactor problems. Candidates should have an honours degree in physics or engineering, and experience in nuclear engineering, reactor technology, and instrumention. Salary £1,175 to £1,525 per annum.—Applications stating age, qualifications, experience, present position and salary, to D Moffat, Director of Establishments, Winsley Street, London, W.1, by November 12, 1956 Quote Reference N/884

HONOURS GRADUATE IN CHEMISTRY required by the British Coal Utilization Research Association for studies of the properties of coa extracts and of the halogenation of coals and allied materials Candidates should have had a least three years research experience, and it i essential that they should be able to adapt themselves to cover different aspects of the field o coal chemistry in addition to their main duties Salary according to age, qualifications, and experience. Five-day week. Superannuation and grading schemes—Apply in writing to Assistan Secretary, Ref. C.64, B C.U R A., Randalls Road Leatherhead, Surrey

CHROMIUM

VOLUME I:

Chemistry of Chromium and its Compounds

Edited by

Martin J. Udy

(Vice-President, Strategic-Udy Metallurgical & Chemical Processes, Ltd., U S.A.)

Size: 9½ *in.* × 6 *in.* 446 *pages* *Illustrated* 88*s. net*

This valuable two-volume monograph brings together the latest accurate data on the sources, properties, manufacture and use of metallic chromium, chromium alloys and chromium chemicals. The field covered by the present volume is denoted by the sub-title. The second volume, which will be ready shortly, describes the metallurgy of chromium and its alloys

SODIUM

Its Manufacture, Properties and Uses

by

Marshall Sittig

(Ethyl Corporation, New York)

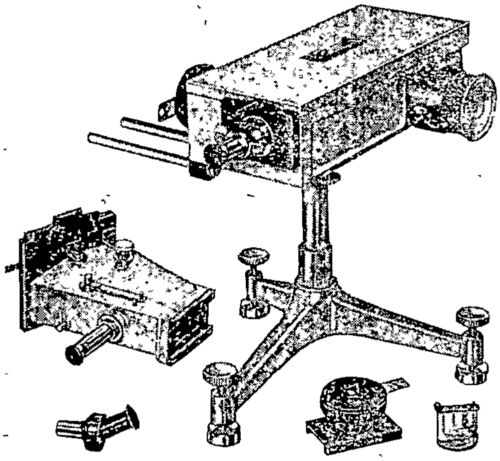
Size: 9½ *in.* × 6 *in.* 537 *pages* *Illustrated* 100*s. net*

This work combines all the information currently important in the manufacture, handling and use of sodium, and also covers its physical, chemical and thermodynamic properties. The book contains 150 illustrations including flow sheets, line drawings and photographs of equipment and actual sodium handling operations.

37 ESSEX STREET, LONDON, W.C.2

PRECISION INSTRUMENTS

Direct Reading Wavelength Spectrometer



for use in the visible spectrum and also, when required, in the ultra violet and infra red. Reading in wavelengths directly.

A camera attachment can be supplied giving the following length of spectrograms :

With quartz prism, wavelength 10,000 A. to 2,200 A., 70 mm.

With glass prism, wavelength 10,000 A. to 3,600 A., 125 mm.

A large range of accessories can be supplied with this spectrometer, making it a really universal instrument, and our staff will at all times be pleased to recommend the equipment most likely to meet special requirements.

ATOMIC ENERGY AND THE BALANCE OF SCIENTIFIC EFFORT IN BRITAIN

IN its first annual report, the United Kingdom Atomic Energy Authority set in the forefront its difficulties in recruiting sufficient scientists and technologists to permit the due execution of its civil and military programmes. It recognized that this situation was only one aspect of the national shortage of technological skill. Less is said in its second report (see p. 717 of this issue) about the staff position, though the recruitment difficulties have not entirely disappeared. The problem presents itself rather as one of the distribution of resources of trained man-power or of the balance of research effort in Britain, and this aspect is the more important with the great increase of interest in the development of nuclear energy as a source of power and in the independent activity of industrial firms in the field of nuclear energy which has marked the past year or so.

In view of the importance of the staff position, it is disappointing to find such slight indication in the report of the magnitude of the Authority's demand for skilled man-power. The figures given show that non-industrial staff increased by some 30 per cent during the year and the industrial staff by 13·6 per cent; but we are not told what proportion of the 10,795 non-industrial staff or 13,178 industrial employees represents technicians or what scientists or technologists. Nor, again, does the report give an idea of the magnitude of the research effort for which the Authority is responsible, even of that which is entered as fundamental research to be charged to the Exchequer; though it is true that the chapters of the report dealing with technical developments and research and devolopment as well as reactor technology make it clear how wide and varied are the Authority's demands for scientists and technologists, and the many fields of knowledge which its research programme involves.

Nor is what little is disclosed about the staff position entirely reassuring. Some 88 per cent of the non-industrial staff taken over had accepted offers of employment when the lists were closed in February 1956, and three-quarters of the Civil servants who had decided against joining the Authority's staff had been released by March 31, 1956; 91 per cent of the industrial staff seconded from the Department of Atomic Energy or taken over from other government departments accepted offers of employment with the Authority. Nevertheless, the expansion during the year was only achieved by an intensive recruitment drive, and although this was reasonably successful in the middle and lower ranges of staff, difficulty continued to be experienced, particularly in the engineering field, in filling the more senior posts.

It may be surmised that, with the considerable advance in the removal of security restrictions from information on nuclear energy emphasized in the report, security considerations will be a factor of diminishing importance in recruitment, though such considerations are likely to be relevant in the appointment of senior staff. There has been, indeed, in general an encouraging desire to enter the nuclear energy field, and a fair supply of candidates for senior posts. Only a small proportion, however, were of the high standard required in this pioneering sphere; and, with the increased activity of private industry in nuclear power development, the Authority has lost a small number of experienced staff to firms entering this field. However, unless the Authority continues to act to some extent as a training ground for industry in this field, its demands for scientific and technical man-power might be viewed with more misgiving. When the Lord President of the Council addressed the Parliamentary and Scientific Committee on nuclear energy on June 13, Dr. G. E. Foxwell and Sir Andrew Bryan expressed anxiety as to the effect of the magnitude of the research effort of Britain in the field of nuclear energy on research in other directions; but Lord Salisbury in his reply did not wholly succeed in removing concern as to the balance of research effort.

What is disturbing in the present report is the magnitude of the effort going into the Authority's recruitment campaign. More than 52,000 applications for non-industrial employment were received during the year, and more than 12,000 candidates were interviewed. Even assuming that these figures relate to the total increase (almost 2,500) in such staff, they represent a considerable tax on man-power in themselves, which it should be worth some trouble to reduce or eliminate.

The report shows that the Authority is fully aware of the wider implications of its activities. It is considering what expansion should be made in its training facilities, particularly for scientific and technical staff, in the light of the White Paper on Technical Education. The Authority is, of course, already through its Isotope School, its Reactor School, and its programme of training for staff from the four industrial teams noted in its first annual report, an important source of technical training in this special field. While this can never represent in magnitude more than a minor but important feature of the Authority's activities, the report shows clearly the value of this contribution to the spread of knowledge and technique in this field. Up to and including the first course in 1956, 199 full-time and 100 part-time students have passed through the Reactor School, while, internally, bursaries are awarded to members of the staff for full-time university education; experiments were made with 'sandwich courses' in which training in a technical college alternates with periods of practical experience in the Authority's establishments, and nine graduates were recruited in 1955 to the scheme for postgraduate apprenticeship.

These figures may seem small; but they represent an important consideration to be taken into account against the Authority's demand for trained man-power, if that were known. The Authority's staff has also made important contributions to technological education in universities, polytechnics and technical colleges by assisting with lecture courses in the nuclear sciences; and specialized lectures have been given to learned societies. Apart from the question whether the Authority is yet doing all that is reasonably possible in these directions—and doing it in the most effective way—it should be noted that the remoteness of most of the Authority's establishments has not prevented such work. Moreover, as the magnitude of the sales of radioactive isotopes both by the Radiochemical Centre and the Isotope Division of the Atomic Energy Research Establishment alone shows, the Authority is itself an industrial undertaking on a considerable scale. Its Industrial Group operates factories, and its participation in technical education thus demonstrates the practicability of the co-operation of industry in technical education in the way in which the Minister of Education has suggested.

There is, however, another related factor to be considered in this connexion to which also the present report directs attention. The Reactor School at Harwell is not simply a technical educational institution. It is an important vehicle for the dissemination of information. The development of nuclear energy in the United Kingdom has led to a situation in which the great bulk of the scientific and technical knowledge has been concentrated in the Atomic Energy Authority and, as the report emphasizes, it is imperative that this knowledge be disseminated if industry is to play its full part in exploiting the commercial applications of nuclear energy.

The Reactor School is one such means. Others described in the report include the issue of a monthly list of unclassified documents, copies of which are supplied to seven 'depository' libraries, in which the documents are freely available to the public, and access agreements with individual firms. The Authority is prepared to enter into such agreements on conditions which ensure that the Authority secures some financial return for commercially valuable information or for the use of patents owned by the Authority, and that firms are not enabled to use the Authority's assistance to build up exclusive rights for themselves. The subject-matter to which access is given must be carefully defined, on the basis of a demonstrated 'need to know', and the firm must observe the security precautions specified by the Authority. Access may be by means of receiving classified reports, or by visits to the Authority's establishments, or—more rarely—by the attachment of staff or secondment from firms to the Authority's establishments for defined periods. Although the Authority can only provide limited facilities in this way, more than a hundred scientists and engineers from British firms were attached to the Authority's establishments at the end of the year under appropriate agreements.

These agreements have proved to be advantageous both to the firms and to the Authority, because attached staff have worked as members of the appropriate research teams and have often made substantial contributions to the work of the Authority. The importance of this method of disseminating information is further illustrated by the new industrial projects to which reference is made in the report. The firm of Associated Electrical Industries, Ltd., for example, is to construct the first privately owned reactor in the United Kingdom, for which the Authority will provide enriched fuel elements on loan terms, and it is understood that in addition to using the reactor for its own long-term research in physics and engineering, and for training its own staff, the Company intends to make it available to universities for graduate and postgraduate training in nuclear science and technology. Two new major groups have entered the nuclear field during the year: Vickers Nuclear Engineering, Ltd., formed by Vickers, Ltd., Rolls Royce, Ltd., and Foster Wheeler, Ltd., are considering the application of nuclear energy in marine propulsion, and the Hawker–Siddeley Nuclear Power Co., Ltd., is initially studying the application of liquid-metal-fuelled reactor systems.

In these circumstances, the dissemination of information should be as efficient as possible and should not be impeded by secrecy considerations unless they can be fully justified. The Geneva Conference last year demonstrated that a high price can be paid for secrecy with no advantage in security. This aspect requires continual re-examination, for although the attitude of the Authority as indicated by this report is reassuring, in practice it could easily happen that information remained classified long after there was any sound reason for it being kept secret. The very scale of the operations of the Authority disclosed by this report makes it essential in the national interest that there should be the widest possible discussion of the complex questions involved. Even now the information is not being supplied which will permit realistic and responsible discussion of such issues as the balance of our research effort, the distribution of man-power and the relation of Britain's effort in the development of nuclear energy to her export trade and to the Colonial development and other assistance she is providing to the more backward countries under the Colombo Plan and in other ways.

The Atomic Energy Authority clearly has enlightened views on such matters; but it was scarcely to be expected that its report would throw much light on the relations of Britain to the proposals for closer European co-operation in the nuclear energy field, whether through the Organization for European Economic Co-operation or Euratom. Its judgment, however, as to the development of export trade in nuclear reactors could well be wrong, and while orders from overseas are likely to follow rather than precede the achievement of nuclear power on a competitive basis in Britain, the demand may well represent a significant part of the total value of the engineering industry's exports earlier than the Authority expects. The Authority could easily under-estimate the capacity of the engineering industry for development in a new field, given the nformation and facilities which the industry itself, nd not some outside body, judges to be essential.

It is at this point that the attitude of the Government becomes important. It is known that Britain s reluctant to co-operate fully in the European tomic Agency which the Council of the Organization or European Economic Co-operation decided on uly 18 in Paris to establish. Questioned in the Iouse of Commons on July 31, the Chancellor of he Exchequer said that it is too early to define the xtent of United Kingdom participation in the gency, but that the United Kingdom will play a ull part in the steering committee which is to draft statute for the Agency. From what Sir Edward oyle, Financial Secretary to the Treasury, said in aris, it appears that, while Britain is prepared to lace its technical knowledge and experience at the isposal of the Agency, the Government is nervous f the supra-national authority which the new agency ill probably possess eventually, and reluctant to ommit itself to full participation.

Obviously, co-operation in the field of nuclear nergy has implications for European co-operation enerally, and participation might involve great ifficulties due to commitments in the Commonealth. A negative attitude, however, has its own rawbacks; and although the British Government esitates with reason to participate in the Euratom roject, in which the proposals for a supra-national uclear energy pool may well involve a degree of ontrol over civil and military uses of nuclear energy eyond what Britain could accept, it is nevertheless ssential to give full support to the more limited roject for a nuclear energy agency, the main purpose f which is to facilitate joint undertakings among ember countries. At the least, if the Government not prepared to participate fully, it should give lear and convincing reasons for its reluctance.

The Atomic Energy Authority's second annual eport does nothing to remove the impression that ver the whole field of nuclear energy the Governent is lacking in imagination. This is true no less regard to European co-operation than in regard secrecy. Just as it may well be disastrous to ritain to be left out when European co-operation in he nuclear energy field gets well under way, so lack f imagination in regard to policies of secrecy and egulations could well frustrate the promising developents in industry to which the report refers. The uthority itself is well aware of the importance of nterprise and imagination in activities dependent rgely on experimental science; but that very factor hould emphasize that the Authority is not necesarily the best judge of the worth of an experiment lsewhere, or of the needs of a firm for some particular iece of information.

This is not to suggest that the present organization f the Authority itself is not reasonably sound and dapted to its purpose. So far as can be judged, it ossesses the freedom of operation and the flexibility hich are so important in a field where initiative and xperiment are vital, as well as readiness to modify lans as the tempo of development increases or new ossibilities emerge. It is at the top, or rather outside the Authority, that doubts exist. As Mr. R. Davey Best points out in a survey of the organization of the Authority in *Public Administration*, very large responsibilities are placed on the Lord President of the Council in relation to the Authority; but the Lord President still has only a very small office to enable him to discharge these and other functions. It is here that the Government appears to be lacking in imagination and foresight. As Lord Salisbury himself said in the House of Lords on December 14, 1953, the Lord President is concerned with main questions of policy, and in particular, the balance of use of nuclear material between the needs of defence, power, biology and so on, so as to ensure that the broad needs of government policy and the broad needs of the country are satisfied. He is also generally responsible for the Government's contact with the world of science and technology and is in a position to be impartial between the different users of nuclear material. Lord Salisbury's address to the Parliamentary and Scientific Committee showed how admirably qualified he is for this vital post, that he appreciates fully the need for flexibility and that decision, for example, between the various types of reactor to be selected for nuclear power stations depends on the considerable research experience now being acquired by the Authority, or, again, the importance of public confidence in the experts working in such fields. This very suitability, however, tends to obscure the importance of two points: first, the necessity for the Lord President to be supported by an adequate staff to enable him to discharge adequately and flexibly his heavy responsibilities for promoting a reasonable balance in the research effort of Britain and the supply and distribution of its trained man-power; and secondly, the need for a direct spokesman of his office in the House of Commons. The very reasons that to-day in practice require the Chancellor of the Exchequer to be a member of the House of Commons demand no less insistently that there should be in the House of Commons a member of the Cabinet who can speak directly and from first-hand knowledge on Government decisions and policy in regard to scientific and technical effort, and who can satisfy Parliament that the great opportunities which nuclear energy has brought about are being fully explored and used with vision, enterprise and decision.

THEORY OF FLOWING WATER AND SILT

An Introduction to Fluvial Hydraulics

By Serge Leliavsky. Pp. xii+257. (London: Constable and Co., Ltd., 1955.) 30*s*. net.

THIS short book by a distinguished expert in river hydraulics is an excellent summary of the various theories, methods and facts bearing upon the flow of water in erodible channels, which are themselves the natural creations of this flow. The current which erodes such a channel is in turn controlled by the ever-changing shape of the channel it has eroded; hence, we are faced here with a problem of successive approximation which converges either to the stable or equilibrium channel of canals and some rivers, or to the fluctuating pattern characteristic of meandering rivers and shifting estuarine channels. Much work has been done, and some progress made, with the equilibrium shape of stable channels transporting both water and silt; but the problem of meandering channels under natural conditions has received less attention, and the causes and factors which control the size and sinuosity of the meanders are still a matter of conjecture.

As might be anticipated, in a field in which active investigation is at the moment being pursued and in which new ideas are constantly being put forward and older theories revised, the historical treatment has much to recommend it. This is the treatment followed in the book, and the author has performed a valuable service in directing attention to much that is suggestive and thought-provoking in the works of earlier engineers. In particular, river engineers will be grateful for the exposition of the rationale and art of river training practised by earlier engineers, which are not widely known and which can still be scarcely improved upon. Also, those concerned with hydraulic models of meandering rivers would do well to ponder the criteria for similitude given by earlier workers—it is clear that attention to earlier laboratory results would have rendered unnecessary a good deal of later experimentation on similar lines.

The basic property of fluvial hydraulics calling for study is the capacity of flowing water to transport from place to place solid particles of greater density than the water itself. In reviewing the numerous attempts at this problem, two distinct lines of inquiry can be traced. While French, German and American research aimed at finding the forces and other mechanical factors acting on the particles individually and so coming eventually to an explanation of the behaviour of the system, the second school, including mainly Anglo-Indian and some Austrian engineers, attempted a study of the macroscopic properties of the system under the simplest conditions—that is, in 'silt-stable' canals and rivers, which neither silted nor scoured over a long period of years. By measuring the dimensions and discharges of such channels, they derived empirical formulæ, correlating the capacity of the stream to transport silt and sand with its main hydraulic characteristics. These formulæ were then used for the design of new canals and proved reasonably satisfactory. While it may appear that the second school cannot achieve great depth of insight into the basic mechanism of transport, it is nevertheless a fact that thus far it is this school which has provided the engineer with reliable design criteria. In fact, although several interesting and possibly significant attempts at practical solutions have been produced by the first school, none of them has yet achieved as wide and universal recognition as those of the second school.

The usual treatment of particle transport by a stream recognizes three different modes of movement: rolling and sliding along the bed; saltation or motion in short hops; and suspension. Unfortunately, the movement of particles along the bed of a stream is complicated by the presence of small-scale ripples as well as the large-scale dunes and shoals. These occur over a wide range of flow conditions in Nature, their size depending on the size of the bed material as well as the hydraulic factors. So far, very little progress has been made with a detailed explanation of the reason for the existence of such ripples. The tendenc in the theories and analyses which have been frame to express bed movement has been either to leav rippling out of account or to force it into the background by incorporating disposable factors the valu of which must be determined by experiment. This lack of an adequate theory of rippling also has adverse repercussions on the investigations of saltation an suspension. For the material travelling in this wa has been taken from the bed by eddies generated b the ripples which may take particles directly int suspension in the manner of a whirlwind or, b sweeping them from the crests of the ripples, start them into saltation. It is perhaps significant that the existing theory of turbulent suspension become obscure and unsatisfactory near the bed, wher ripples become a dominant feature. There is n doubt that, whatever progress may be achieved i the future in this branch of physical science, our knowledge will remain incomplete and empirical s long as this particular phenomenon remains unexplained in terms of mechanical theory.

G. H. Lean

FROTH FLOTATION OF MINERALS

Principles of Flotation

By Dr. K. L. Sutherland and Dr. I. W. Wark. Pp
xv+489. (Melbourne: Australasian Institute o
Mining and Metallurgy (Inc.), 1955.) n.p.

THIS is a revised and enlarged edition of Dr. I. W. Wark's "Principles of Flotation" published i 1938. It is to be welcomed, for there have bee considerable advances in the knowledge of th principles of froth flotation of minerals during th past twenty years; and during that period the process of froth flotation has been used much mor extensively than before in mineral processing. Sutherland and Wark and their co-workers hav made noteworthy contributions to our knowledge o flotation; it is inevitable that they should dra freely on their own results and on those of the colleagues. Their results, many of which are given in detail, are carefully discussed and compared wit those of other workers; and, although it is not th intention of the book to deal with the technology of flotation, the bearing of the results on the practic of flotation is made clear.

The flotation process is influenced by many variab factors; indeed, a froth flotation cell in operation presents a very complex system because of the inte actions between certain of the variables, some o which cannot readily be controlled by the operato In their book, Sutherland and Wark deal with som of the important factors, but they are chiefly concerned with the action of the four groups of flotation reagents—collectors, frothers, activators and depressants—and the underlying principles of their roles in flotation. The most important chapters are concerned with the variables of flotation, physica principles, adsorption, experimental methods, flotation of sulphide minerals by collectors of the xanthat type, depressants, activation, joint effect of depressan and activator, flotation of superficially oxidize sulphide minerals, paraffin chain salts as collector (about one-quarter of the book); kinetics of th flotation process, colloids and slimes in flotatio electrical properties of surfaces in relation to flotatio and frothing. The text is supported by a bibli raphy of nearly six hundred references ; this is not, nd is not intended to be, exhaustive, but each eference mentioned is touched on in the text. It ndicates the careful consideration given by the uthors to available results.

It should be emphasized that this book is concerned vith principles and not with practice. There are no escriptions of flotation machines or flotation plants, lthough certain types of machine are referred to n the chapter on kinetics. The treatment of many pecific minerals by froth flotation is mentioned, but t is surprising that the froth flotation of coal, which s becoming more and more important in the preparaion of coal, is not mentioned (except incidentally in onnexion with the adhesion of bubble to mineral).

The book is well written and well produced. There re few errors or misprints, but the error in definition f Reynolds's number given at the foot of p. 363 hould not have escaped detection when the proofs vere checked. The indexes are very good. This is n outstanding book, not suitable for the beginner ut of considerable value to the advanced student, he research worker and the inquiring operator of the otation process and, not least, to the teacher.

S. G. WARD

THE POLAR AURORA

he Polar Aurora

y Prof. Carl Størmer. (International Monographs n Radio.) Pp. xvii+403+34 plates. (Oxford: larendon Press; London: Oxford University ress, 1955.) 55*s*. net.

IT would be presumptuous to attempt to 'review' the present volume by Prof. Carl Størmer on the olar aurora—a field of study which he has truly ade his own. At an advanced age he has collected ogether in book form the greater part of his esearches on the observations and interpretation of he aurora. Everyone interested in this fascinating henomenon will be greatly indebted to him, not nly because, as he reminds us in the preface, his ong series of papers on the subject is difficult to btain in complete form, but also because of the nvaluable and extensive theoretical investigations hich the book contains.

On several occasions Prof. Størmer has related how is interests were diverted from the field of pure athematics by the striking experiments carried out y his compatriot Birkeland on the deflexion of athode rays in the field of a uniformly magnetized phere. His great mathematical skill served him well n discussing the idealized, but nevertheless difficult roblem of the motion of a charged particle in the eld of a magnetic dipole with which he sought to lustrate the results of Birkeland's experiments. he great variety of orbits possible, beautifully illusrated by many plates in the book, is testimony to he infinite patience of the man who pursued the aborious calculations involved. These theoretical nvestigations, which form the second part of the ook, were primarily intended as a contribution to he corpuscular theory of the aurora in the form roposed by Birkeland. The trajectories derived by tørmer indeed showed many analogies with the orms of the aurora, and though the neglect of the utual interaction between the corpuscles in the tream makes the bearing on auroral theory uncerain, it is most gratifying that the theory has found a secure place in the interpretation of the global incidence of cosmic rays.

The first part of the book is concerned with the observation, forms, height measurement and spectroscopy of the aurora and also with its close connexion with geomagnetism. Our present knowledge about the position of the aurora in space is indeed almost entirely due to the photographic measurements of Størmer and Vegard ; the methods used as well as the results they obtained are extensively described, as are also the geographical distribution and the methods of observing and photographing the aurora. Here will also be found an account of Størmer's important discovery of sunlit auroræ and of their intensity and colour. Other chapters are devoted to the auroral spectrum, auroral radio wave emission and radio echoes from the aurora. The author also considers such questions as the possibility of the existence of electrical currents outside the Earth's atmosphere, reviews the spectroscopic evidence for a solar corpuscular stream between the Sun and the Earth and considers the absorption of corpuscular radiation in the atmosphere and the emission of electric corpuscles from the Sun.

Though the accent in the theoretical parts lies on the Birkeland–Størmer theory of the aurora, brief accounts of other theories are given ; and perhaps because in this field one is too apt to indulge in speculations, Prof. Størmer has kept almost entirely to verifiable facts. Thus, though it is generally believed that magnetic storms and auroræ are due to solar corpuscular streams, the evidence so far has been indirect and not entirely unassailable. The detection of hydrogen lines in the spectrum of the aurora by Vegard, Gartlain and Meinel clearly points to the entry of protons in the atmosphere. Nevertheless, as Størmer seems to imply, definite evidence that these originate from the Sun is perhaps still not definite.

The book is very well produced and the typography excellent.

V. C. A. FERRARO

NUCLEAR POWER ENGINEERING

Thermal Power from Nuclear Reactors

By Dr. A. Stanley and Oliver E. Rodgers. Pp. xiii+229. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1956.) 7.25 dollars; 58*s*. net.

A MECHANICAL engineer, noting the title of this book and reading the introductory remarks on the jacket, might expect to find a work designed to give him an idea of the special difficulties associated with the design of a nuclear power plant. If so, he would be disappointed. He would, perhaps, be surprised to find nearly one-third of it devoted to an elementary treatment of familiar topics such as thermal stress in isotropic elastic solids, laminar and turbulent pipe flow and convective heat transfer. Very little space is devoted to the fundamentals of topics such as thermal stress in non-isotropic and plastic materials, thermal shock, and transient heat transfer, which have increased in importance since the advent of nuclear power, and which are less familiar to the non-nuclear engineer. No literature references to specialist papers are given.

In restricting themselves to fundamentals, the authors have avoided dealing with any particular reactor system. This is a pity, since only by so doing can the real engineering difficulties, the necessity for special materials and the economic incentives for high heat release-rates, be brought out. Although the choice of engineering topics is in question, those chosen are dealt with in a very elegant and satisfying manner. The text is concise and enjoyable, and the layout of the equations admirable.

The chapter on the reactor equations is particularly interesting, since slowing down and diffusion theories are dealt with in an unusual manner. The treatment has the great merit of uniformity and coherence, and teachers of this subject would do well to study it. The approach is direct and does not involve the use of such concepts as laboratory and centre-of-mass reference frames, buckling or reactor Laplacian. Dimensional analysis is applied to yield some interesting parameters, and a section is included on numerical methods. No treatment is given of fine-structure effects in natural or low-enrichment reactors. The value of this chapter to the engineer would be greatly improved if a comparison with experiment were provided.

There are two chapters on kinetics and shielding respectively. In the latter only basic principles are dealt with, and no design information is given.

In general, what has been done has been well done; but the whole book does not, in my opinion, justify the description given on the jacket. If the authors could be persuaded to write a book on reactor theory, expanding the treatment given in the present book, and dealing at greater length with numerical methods, a very useful work would result.

W. MURGATROYD

HUSSERL'S 'FIRST PHILOSOPHY'

Edmund Husserl

Erste Philosophie (1923/24). Erster Teil: Kritische Ideengeschichte. Herausgegeben von Rudolf Boehm. (Husserliana, Band 7.) Pp. xxxiv+468. (The Hague: Martinus Nijhoff; London: B. T. Batsford, Ltd., 1956.) 26.25 guilders; 52*s.* 6*d.*

THIS, the latest addition to the series of 'Husserliana' to be issued from Louvain, is of exceptional importance in that it bridges the gap between 1913, when Husserl's "Ideen" appeared, and 1928, which year witnessed the advent of his "Formalen und transcendentalen Logik". In 1923–24, however, the master had delivered his great course on a 'First Philosophy' at the University of Freiberg-im-Breisgau, and it is the historical content of these lectures which is now before us. His treatment of the classic problem of phenomenological reduction is reserved for the next volume, to be published in due course.

The structure of the present work is tripartite. First comes an examination of the whole field from Plato to Descartes. This is followed by a close scrutiny of the initiation by Locke of an attempt in egology, and of the questions which such studies have generated. Then Husserl traces in minute detail the development of sceptical prototypes of phenomenology by Berkeley and Hume, followed by the rise of dogmatic rationalism. These highly specialized sections are rounded off by a large number of appendixes, together with some subsidiary remarks concerned, for the most part, with textual criticism.

Taking these main divisions in order, Husserl is at great pains to stress (what of course is well known and appreciated historically) the accidental character o the term 'metaphysics', in its Aristotelian setting and to fasten upon 'first philosophy'—which incidentally was very nearly equivalent to theology—as the potent phrase for the gradual build-up toward a conscious phenomenological system in the West The claim to do this is made not only to avoid th vagueness inherent in any structure of metaphysics but also and more positively to establish a disciplin of first philosophy as basic for all science. Thi pattern of thought excludes the possibility of switching over at any period in history from concept which are fundamentally devoid of scientific conten to those of scientific value. In a word, the world o thought must begin how it means to go on. That i has not always consistently done so is probably major factor in the recurrent crises (judgments) i European civilization, each one carrying the risk o a retrogression into barbarism. Yet phenomenolog —as first philosophy—is closer to theology than som of Husserl's followers might always be ready t grant. He speaks of a 'philosophia perennis' in term not altogether different from those of St. Thoma Aquinas.

In considering the period leading on to Locke' stress upon "actions of our own minds", the distinctio between the empirical ego and the pure ego i important. The former concept is that of a numbe of conscious acts of which the individual can becom aware by immediate introspection. There is a connexion here with Hume's 'bundle' theory, accordin to which the self consists of an aggregate of dynami states, continually changing in a way suggestive of revival of the philosophy of Heraclitus. In contradistinction, the pure ego is non-empirical, and i more in the nature of an inference from any dat obtained by introspection.

The basic claim of phenomenology lies close a hand, which is that observation is not so muc 'straightforward' as reflective. The former is descriptive of objects *per se*, the latter of objects intentionally. The difference is significant because, as Samue Alexander once declared, the whole force of æsthetic appreciation may reside in contemplation, that is, i the power to reflect upon things (even our ow handiwork), rather than merely to use them.

Husserl pays gracious and generous tribute, in th section dealing with phenomenological prototypes, t the genius of Berkeley regarding the influence whic his pattern of thought has had upon the moder empirical theory of knowledge. His was, in fact, th first systematic attempt to make the world as w know it—as viewed subjectively—theoretically comprehensible. The misinterpretation, however, of th problems of constitution arises primarily from a lac of insight into the immediate field of consciousness as might be expected when the fundamental assumptions are naturalistic in character. Nevertheless phenomenology as we perceive it in the twentiet century has developed from a variety of sources metaphysical as well as empirical; and this is as i should be, so long as the former always connote 'first philosophy', rather than its fortuitous positioning by Andronicus of Rhodes.

For the scientist, phenomenology is valuable i that it aims relentlessly at rigour, not merely as discipline, but constructively by placing 'the matter themselves' at the centre of his mental image; an in so far as they are self-given, he may assuredl accept them as true knowledge.

F. I. G. RAWLINS

Thorpe's Dictionary of Applied Chemistry

Fourth edition, revised and enlarged. Vol. 12: General Index. Pp. iv+187. (London: Longmans, Green and Co., Ltd., 1956.) 42*s.* net.

With the appearance of a general index, which forms the twelfth volume, the fourth edition of "Thorpe's Dictionary" is now complete. This harvest of chemical knowledge is safely in, and this s an opportunity to congratulate those who have helped in the gathering. Boswell reports himself as saying to the author of another dictionary: "You did not know what you was (*sic*) undertaking". To which the author replied: "Sir, I knew very well what I was undertaking—and very well how to do t—and have done it very well". No better summing-up can be found for "Thorpe's Dictionary".

It is fitting to recall those who have undertaken the editorial work during the past twenty years and so placed us in their debt. Sir Jocelyn Thorpe was one of the two first editors of the fourth edition and saw the first six volumes published. Next came an editorial board consisting of Sir Ian Heilbron, Prof. H. J. Emeléus, Prof. H. W. Melville and Sir Alexander Todd. The assistant editors were Drs. L. N. Owen and A. J. E. Welch. The central figure throughout was Dr. Martha Whiteley, who died this year at the age of eighty-eight (see *Nature*, June 30, p. 1202), and who was editor for the whole period, in addition to her work for earlier editions and supplements. It s peculiarly appropriate that Dr. Whiteley was able to pass the whole edition through for publication, ncluding this index. *Finis coronat opus.*

R. P. Linstead

ntroduction to Reference Books

By A. D. Roberts. Third edition, revised. Pp. vii+237. (London: Library Association, 1956.) 16*s.* (12*s.* to L.A. Members).

The first edition of this book was based on lectures given during the 1945–46 and 1946–47 sessions of the School of Librarianship at University College, London, and it remains designed essentially for those taking up a career as librarian. For the scientist it may well give a surprising revelation of the wealth of material which awaits him in any inquiry outside his special field; but although Mr. A. D. Roberts has a short chapter on the literature of special subjects, a chemist, physicist or engineer will be surprised at the absence of any mention of works to which he is wont to turn at the first introduction to the literature of his subject.

Mr. Roberts has his answers. He has sought to avoid compiling an enormous list of titles, and in his successive chapters—on encyclopædias, dictionaries, directories and other business publications, bibliographies, serials, indexing and abstracting services, current national bibliographies and bibliographies of books in print, bibliographies of older British books, directories of societies and institutions, government publications, bibliographical works of reference, and atlases and maps—he describes clearly the kinds of reference books available.

Surprise at any particular omission should accordngly be balanced against the clear picture of the material at his disposal which is set before the student; and it is probable that the student who conscientiously follows the guidance and hints which he is given will come across the particular works omitted if they are relevant to any particular inquiry on which he is engaged.

R. Brightman

Vector Analysis

By Homer E. Newell, Jr. (International Series in Pure and Applied Mathematics.) Pp. xi+216. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 41*s.* 6*d.*

In the first eight chapters of this book, vector calculus is developed from the elements to the operator ∇; the integral theorems of Gauss and Stokes, and the standard elementary work on vector fields. The treatment is geometrical in flavour, but analytical difficulties are not ignored; when they are not completely disposed of, the reader is warned of their existence, and indications of how they may be overcome are given. In the last three chapters, Mr. H. E. Newell has selected as his chief application, apart from some work on kinematics, an account of electromagnetic theory.

In the preface, Mr. Newell deplores the familiar fact that students "who have been exposed to a course in vector analysis" so seldom learn to think vectorially. The remedy, for the student of applied mathematics, is surely to be found in a thorough integration of theory and applications; each new step should be introduced as the answer to a demonstrable need, and should be buttressed immediately by varied and significant applications. In the present book, as in so many others, the new concepts often come in rather abruptly, and too much of the buttressing is left to the exercises for the reader.

Mr. Newell has many merits as an expositor, and it is therefore to be regretted that he has not given the fully integrated account which the young student of physics and engineering would find so valuable.

Lithium Aluminum Hydride in Organic Chemistry

By Prof. Vukić M. Mićović and Dr. Mihailo Lj. Mihailović. (Serbian Academy of Sciences' Monographs. Vol. 237. Section for Natural Sciences and Mathematics, No. 9.) Pp. xi+193. (Beograd: Serbian Academy of Sciences, 1955.) 3 dollars.

This is an interesting account of the more important uses of lithium aluminium hydride, or, as the authors have it, lithium aluminum hydride. There are twenty-five chapters. Chapter 1 is concerned with the hydride as a reducing agent in organic chemistry, and Chapter 2 with its formation and properties. The next chapter deals with reactions of the hydride with inorganic and organometallic compounds, and Chapter 4 with its reactions with compounds containing active hydrogen. Then there is a chapter devoted to general experimental procedures, with notes on fire hazards and the like.

Chapters 7–24 cover the reactions of lithium aluminium hydride with compounds containing the commoner functional groups. The last chapter in the book reviews the various suggestions offered for the mechanism of reduction by the hydride.

Considering the tremendous literature of the subject, the authors have done very well indeed to produce, as they have, a small, readable volume which gives the general chemistry, shows up the important features, and gives no fewer than 1,732 references to the literature. The book is written by two men who have themselves experimented with lithium aluminium hydride and therefore are capable of appreciating its amazing versatility as a reagent. The chemistry is well described, with clear reaction formulæ.

PERMAFROST RESEARCH IN NORTHERN CANADA

By ROBERT F. LEGGET

Director of the Division of Building Research, National Research Council, Canada

A NEW Northern Research Station for Permafrost Research was recently dedicated at Norman Wells, Northwest Territories, by Dr. E. W. R. Steacie, president of the National Research Council of Canada. The opening of this far northern laboratory coincided with a visit of members of the National Research Council to the northwest of Canada. This visit and the establishment of the station at Norman Wells are significant indications of the steady awakening of Canada's northland.

The tour of the members of the National Research Council followed the regular summer meeting of the Council, which was held in Saskatoon instead of Ottawa as is the usual practice. Two years ago the Council had its first special summer meeting in Newfoundland, visiting this newest of the ten provinces of Canada in order to demonstrate the interest of the Council in the scientific and technical problems of this island province. The visit to northwestern Canada was arranged in view of the success of the visit to Newfoundland, and in order that the members of the Council might gain personal acquaintance with the great Mackenzie River valley, seeing also something of current developments on the arctic coast.

The party numbered about thirty. Most of the members made the tour by a specially chartered aeroplane; others were able to make most of the journey using regular commercial airline services. The party proceeded from Saskatoon to Beaverlodge on the northern shore of Lake Athabasca, where they inspected one of the major uranium mines of Canada. They then proceeded to Yellowknife, the mining centre of the Northwest Territories, and there inspected an operating gold mine. The next part of the journey was to Norman Wells, which the party used as a centre for special flights to the arctic coast. One of these was to Tuktoyaktuk, where the members were able to visit an Eskimo village and one of the DEW-line radar early-warning stations now under construction. No greater contrast between new developments in northern Canada and its traditional life could be imagined. The other special flight was to the existing town of Aklavik, located in the middle of the great delta of the Mackenzie River, at the meeting point of Indians from the south and Eskimos from the north. This principal settlement of the arctic coast is shortly to be moved to a new site on the east rim of the delta. The party was able to visit the new site and to see the start of construction for the new Aklavik.

After inspecting the facilities of Imperial Oil, Ltd., at Norman Wells, and the new National Research Council research establishment, the party flew up the Mackenzie valley to Fort Simpson, where a special Experimental Farm of the federal Department of Agriculture now has more than 50 acres under active and successful cultivation. Flight was then made over the mountains to Whitehorse, capital of the Yukon Territory, where local engineering developments were inspected prior to the return of the party to Edmonton. During this journey of more than 8,000 miles, the Council held two special dinner meetings, at Yellowknife and Whitehorse, where they met leading local residents and had an opportunity of bringing research to the attention of those concerned with the development of these northern communities.

It was during the visit to Norman Wells that Dr. Steacie, in the presence of most of the members of the National Research Council and of a large proportion of the local population, officially opened the two new prefabricated buildings of the Northern Research Station of the Council's Division of Building Research. The buildings are of simple wooden construction, designed and constructed for service in the rigorous climate of Norman Wells. They are so arranged that they can be moved in the future if it should be found eventually that the new Aklavik will be a more suitable location for the station. The residence measures 24 ft. by 48 ft. and can accommodate five or six research workers. The other building, 24 ft. by 72 ft., is a fully equipped soil mechanics laboratory with an associated workshop and garage for the special drilling and sampling equipment needed for permafrost investigation.

Norman Wells was selected as a site for this research establishment after careful survey of all possible sites in the northwest of Canada, most of which lie along the banks of the Mackenzie River. It is the present terminus for the wheel-equipped aircraft used on the regular commercial route of Canadian Pacific Air Lines; it is thus conveniently located for transportation. It is the site of a small oil field and oi refinery of Imperial Oil, Ltd., so that this Company's shop and service facilities are available. These have been most generously placed at the disposal of the National Research Council staff at the station at Norman Wells. The building programme of Imperia Oil has itself provided most useful information and experience with the special problems created by construction on permafrost.

More than one-third of the land area of Canada is underlain by perennially frozen ground. In all this northern area, the temperature of the ground, below the depth to which daily temperature-fluctuations are experienced, is 32° F. or colder. The depth at which freezing temperatures occur varies from a relatively few feet near the southern boundary to well over one thousand feet in the Arctic Archipelago. When the ground consists of solid rock, o of dry sand and gravel, the sub-freezing temperatures are of scientific interest but of little practical consequence. When, however, the frozen ground consists of water-bearing soil, and especially if the soil is silt (as is usually the case, in view of the recent glacial history of most of northern Canada) the practical consequences can be serious indeed i the natural temperature regime of the ground i disturbed.

It is to describe such conditions of terrain tha the word 'permafrost' has come into general and popular use within the past two decades. Philologically, objection can be raised to the name[1] particularly since its generally accepted use really implies its application to all perennially frozen ground and not just to frozen silt; but it appears to be oo late now to attempt to change this popular usage.

In natural circumstances, perennially frozen silt and other water-bearing soils will thaw out to shallow depths as the summer season progresses. Depths of thaw up to two, and sometimes even three, feet have been observed beneath the almost invariable surface vegetal cover, to which another popular name, muskeg', is usually applied. Re-freezing takes place apidly following the end of summer heat. The water thus released beneath the muskeg cover of so much of northern Canada is what makes summer overland travel so difficult and hazardous in this egion. The regular thawing and re-freezing is associated with the polygonal surface patterns frequently found in perennially frozen areas.

When it is necessary to carry out in the north engineering operations such as the building of roads and airports, and the erection of all but the smallest permanent structures, troubles may quickly develop when the ground is disturbed if it is found that the site is underlain by frozen silt. Once the natural vegetal cover is removed, more extensive thawing than usual will occur. Since the frozen silt will usually prove to be saturated or even super-saturated when thawed, and as it is usually slow draining, road and airport construction in permafrost can be extremely troublesome. Correspondingly, the heat ost from buildings can cause permanent and serious changes to the natural soil and ground temperature regimes, thus necessitating unusual foundation designs.

The first objective of the new research station at Norman Wells is to provide the necessary laboratory facilities and field-investigation equipment for the study of such practical building problems of the Canadian north, problems which have been multiplied n recent years as the development of the north has accelerated and as the standards used for northern buildings have been improved. Accurate study of soil conditions at proposed building sites is a first requirement. This has led to the development of special test-drilling techniques, such that cores of frozen soil can be obtained for study and analysis, and of somewhat unusual field-photographic procedure for the investigation of the exact ice formation n samples without recourse to elaborate (and costly) refrigerated equipment for sample storage and transport.

The new research station at Norman Wells will serve as a centre for this specialized field-research, the terrain near the station providing a most suitable area for test installations and investigations. The laboratory is fully equipped for the detailed study of the physical and mechanical properties of the soil content of samples of permafrost. Laboratory and workshop facilities will be used for the preparation of the extensive instrumentation required for the investigation of the ground-temperature regime in undisturbed areas and at the sites of engineering works.

The study of such practical problems is but one part of the assignment of this Northern Research Station, the other being a more general scientific investigation of permafrost as a natural phenomenon. Plans have been developed for permanent installations which will eventually demonstrate whether the permafrost of Canada is a static condition or one which is changing with time. The staff assigned to this work have, however, been diverted almost completely since the start of their work in 1952 (in temporary quarters) to the necessary study of permafrost at the existing town of Aklavik and to the extensive survey investigations carried out before the new town site was discovered and finally selected. Studies are continuing at both the new and the old sites and should eventually yield results of unusual significance.

Among other scientific projects in view is the drilling of a deep hole for the study of deep-ground temperatures[1]. This will be complementary to those already in use at Point Barrow, Alaska, and Resolute Bay, Northwest Territories. Investigation of temperatures in *pingoes* is already under way and other studies of the variations of ground temperature at shallow depths. With the new laboratory facilities now available, and the new town site for Aklavik well started towards its full development, it is hoped that the long-planned research into the more scientific problems of permafrost in northern Canada can soon be prosecuted as planned[2]. The Norman Wells station will be available for use by guest workers with the National Research Council. It is a satisfaction to be able to conclude this note by reference to the first such guest workers, two British geologists, who are visiting northern Canada on a special mission.

U.K. ATOMIC ENERGY AUTHORITY

SECOND ANNUAL REPORT

THE second annual report of the United Kingdom Atomic Energy Authority*, covering the year ended March 31, 1956, follows the pattern of the first annual report. The dominant feature of the year has been the great increase of interest and activity in the development of nuclear energy as a source of power for peaceful purposes, which has coincided with a considerable advance in the removal of security restrictions on information in this field. These questions and also the implications of the staff position in relation to the man-power situation in Britain and in regard to technological education are discussed elsewhere. For the rest, it may be said that generally the report presents a concise and readable picture of technical developments during the year, many of which have already been made known in the Press. The report, however, puts them in their proper perspective. Moreover, the Authority recognizes so clearly the importance of a clear public understanding of exactly what it is doing that it has supplemented the report with an admirable illustrated summary*, which should bring home to the

* United Kingdom Atomic Energy Authority. Second Annual Report for the period 1st April 1955–31st March 1956. Pp. iv+46. (London: H.M. Stationery Office, 1956.) 2s. 6d. net.

* Atom 1956: An Illustrated Summary of the Second Annual Report of the United Kingdom Atomic Energy Authority. Pp. 24. (London: H.M. Stationery Office, 1956.) 1s. 6d. net.

ordinary citizen the nature of the problems with which the Authority is faced and the magnitude of its operations.

During the past year, nuclear power has become for most countries a matter not of conjecture but of dates, and comparative costs and the increase in activity of industry in the United Kingdom and of governments and industry overseas constituted a new feature of national and international affairs. Nevertheless, there has been no reduction in the Authority's activities on the defence side. The nuclear weapons programme, and particularly the development of thermonuclear weapons, continued to have high priority, and the rate of increase of staff was higher in the Weapons Group than elsewhere in the Authority, the total staff of which increased from 19,895 in April 1955 to 23,973 in 1956. During the year, the Authority decided that the work of the Weapons Group, under the direction of Sir William Penney, should include responsibility for research into, and development of, nuclear reactors for military application.

As a measure of overseas interest in the British nuclear energy programme and of the Authority's overseas contacts, the report refers to visits to the Authority's establishments during the year by representatives of thirty-six countries. The new full-time member of the Authority appointed in October, Mr. W. Strath, is largely concerned with overseas atomic energy organizations, as well as with raw material procurement and the Authority's relations with industry. Construction of new capital facilities continued at almost all the Authority's establishments during the year; but Harwell has now almost reached the maximum size compatible with efficient management and the avoidance of unreasonable pressure on the facilities of the surrounding countryside. Research and development, however, continue to demand more scientific staff and working space, and the Authority is examining new sites with the view of setting up a further major research establishment to which new research and development projects could be directed. Additional net expenditure of £3,550,000 was required for 1955–56, beyond the estimate of £50,562,000 presented to Parliament in February 1955, mainly to implement the Government's decisions to develop thermonuclear weapons, to carry out a nuclear power programme and to increase the output of plutonium, for which purpose three new units of the Calder Hall type are to be built, one at Calder Hill and the others at Chapel Cross, near Annan. The net estimate for 1956–57 presented to Parliament in February was for £68,242,000.

The Authority has also faced a major task in establishing commercial accounting systems throughout the organization. A foreword to the balance sheet appended to the report points out that the whole of the cost of operation of factories by the Industrial Group is regarded as recoverable in the price of its products, and expenditure on research and design in aid of future projects is carried forward for later amortization and recovery. The whole of the cost of operation of the Research Group, less proceeds of sales of radioactive substances, electronic equipment and other income, is regarded as the cost of fundamental research in the nuclear energy field to be borne by the Exchequer. Under contract from the Ministry of Supply, the Weapons Group undertakes the production of components for weapons and research work in connexion with weapons; and the cost of operation of this Group, including that c other advanced research, less the amounts charge able to the Ministry of Supply for production an research, and other income, is regarded as a charg to be borne by the Exchequer.

The spate of new discoveries, most of them on th North American continent, has removed the dange of a world-wide shortage of uranium. For its curren uranium imports the Authority continued to depen on contracts placed by the Combined Developmen Agency on behalf of the Authority and the Unite States Atomic Energy Commission, and has receive the first shipment of concentrates from the mines a Rum Jungle and at Radium Hill, Australia. A extension of the contract for the supply of uraniu ore and concentrates from the Shinkolobwe mine i being negotiated and the output of uranium concentrates from the Transvaal and Orange Free Stat mines continues to grow. During the year, the firs contracts were signed for delivery of uranium direc to the United Kingdom, and steps were taken t foster an interest in uranium prospecting in th Central African Federation. Technical development in regard to materials noted in the report include among chemical methods of extracting uranium, th publication of an account of the ion exchange process in which work the Radiochemical Group of th Chemical Research Laboratory (Department c Scientific and Industrial Research) co-operated arrangements to create additional capacity for production of graphite in the United Kingdom an investigation of the production of special grades c graphite for future reactors, the change from calcium to magnesium in the reduction of uranium tetrafluoride to metallic uranium and the continued manufacture of fuel elements to meet the needs of Bepo an of the Windscale piles. Further sections of the gaseou diffusion plant at Capenhurst have been commissioned and the output of the plutonium-producin piles at Windscale has been further increased Steady progress has been made in the developmen of maintenance techniques for use inside the pil shield, thereby easing the severe limitation on desig and choice of equipment. Chemical processe developed at Harwell for the complete separation c the fissile uranium-233, fertile thorium and th radioactive fission products from neutron-irradiate thorium have been operated on a small pilot-plan scale.

The report gives some particulars of progress wit the prototype nuclear power station at Calder Hal and the fast breeder reactor at Dounreay, and satisfactory progress has been made with the Harwe swimming-pool reactor (named Lido) for researc and development related to the problem of shielding The heavy-water-cooled and moderated therma reactor, Dido, was expected to come into operatio towards the end of July 1956 and is to be used fo a limited amount of engineering loop work, an work has been commenced on the design and manufacture of special experimental equipment an devices for the production of isotopes and on th design and construction of the first of the engineerin loops to be installed in the heavy-water high-flu reactor, Pluto, to test the technology of advance reactor systems. While the first nuclear powe stations will be built away from heavily built-u areas, the Authority has set up a panel of its ow specialists with representatives of the electricity undertakings to consider the problems of the sitin of reactors.

The Authority's reactor research programme is further described in a separate chapter of the report. A substantial amount of work is still being done on the graphite-moderated gas-cooled reactors being designed by industry for the Central Electricity Authority, and several loops have been built to study the corrosion of carbon steels and stainless steels under the conditions likely to be experienced n pressurized-water reactors, while the use of organic liquids such as diphenyl and terphenyl as alternative to the water moderator and coolant is being investigated. Reactor physics and metallurgical and engineering investigations are being carried out on the alternative reactor using graphite as a moderator and liquid sodium as coolant. In addition to the organic system just mentioned, four other reactor ystems are being examined for attaining a much higher fuel-utilization by breeding: the fast reactor system; the homogeneous aqueous reactor system, which attempts to achieve breeding in the uranium-233–thorium system, with very low fuel costs; the liquid-metal fuelled reactor system, using a graphite moderator and enriched uranium dissolved in a liquid metal; and the high-temperature gas-cooled reactor system. Treatment of irradiated uranium by solution in acid and extraction with organic solvents continued to be a successful method for separating plutonium and recovering uranium for re-use on the ndustrial scale, and pilot-plant experience has been gained of the process for the extraction of uranium-233 from irradiated thorium. Work on the production of a controlled thermonuclear reactor, in which the two main problems to be solved are to bring a mixture of the light elements to a temperature in the region of 100 million deg. C., and to maintain this long enough for the energy released in nuclear fusion to exceed that required to heat the fuel, is still in the laboratory stage.

Besides occupational health problems, the Authority pays much attention to those of waste disposal, including measures to ensure full protection of the public from possible exposure to radioactive materials. Sales of radioactive isotopes steadily increased, totalling £483,000, rather more than half of which was for export; the number of consignments was 22,378 compared with 18,835 in 1954–55. The potential uses of radioactive by-products in industry is being actively explored by the Technological Irradiation Group of the Isotope Division, working in close co-operation with industry, and the biological application of irradiation in sterilization and mutation is being actively studied. Antibiotics which are normally destroyed by heat sterilization can be completely freed from bacteriological contamination by simple irradiation. Some 15,000 curies of cobalt-60 have been made and loaded into machines for cancer teletherapy and for industrial irradiation. Among new applications of radioactive isotopes may be mentioned the use of ammonium phosphate containing radioactive phosphorus to investigate the pollution of beaches by sewage; and the use of weak radioactive solutions to detect leaks in water mains and oil pipe-lines up to twenty miles in length.

During the year, 167 students attended the normal four-week course in the Isotope School and 104 attended special courses. The Reactor School at Harwell throughout the year gave training to staff from industrial firms on the construction and operation of nuclear reactors; and while the export of nuclear reactors will be the responsibility of industry, it will fall to the Authority to provide the necessary fuel elements. The Authority expects to be able to provide natural uranium fuel elements to match whatever volume of export business is secured in the foreseeable future. Up to the present, twenty-two licences have been granted to United Kingdom firms to use inventions owned by the Authority, three to United States firms, one to a firm in West Germany and one to a firm in France.

EFFECTS OF ATMOSPHERIC POLLUTION IN FORESTRY

DURING the recent Sheffield meeting of the British Association, the morning session on September 4 of Section K* (Forestry) was devoted o four papers on "Forestry in Industrial Areas, with special reference to Smoke Pollution".

Mr. E. M. Conder (Forestry Commission), in a ontribution on "Some Problems of Private Forestry in the Industrial Areas", pointed out that air pollution is not the sole cause of the lack of satisfactory oniferous tree growth in the immediate vicinity of arge industrial cities, for fire and theft are also esponsible in some measure. From experience in Lancashire, the Black Country, the Nottinghamshire oalfield, and parts of South Yorkshire, he considers ycamore, beech, elm and poplar the most successful imber-producing hardwood species, with other generally resistant but subsidiary species as follow: orse chestnut, birch, holly, rowan, whitebeam, ommon alder. Only the black pines (with particular mphasis on the Austrian variety) and, in certain circumstances, Japanese larch, can be recommended mong the conifers. Besides these there are few pecies to suggest, apart from monkey puzzle, yew nd perhaps the cedars and Lawson's cypress. Trials with *Pinus contorta* are as yet too young to provide conclusive material and, while Scots pine may be vigorous initially, subsequent development is poor. Mr. Conder suggested that, in high valleys and on hill slopes, trapping of injurious gases by prevalent low cloud may explain the serious effects at these sites. It was emphasized that in surveying pollution effects, attention must always be paid to the fertility of the soil and, among climatic factors, to the influences, in particular, of elevation and exposure.

Atmospheric pollution effects in Yorkshire were discussed by Mr. A. J. Grayson (Forestry Commission), who suggested that though pollution as generally viewed is deleterious, it may imply useful additions to the existing natural 'chemical climate' before the concentration of individual pollutants or combinations gives rise to injury. Historical evidence shows something of the extent to which changes of species in plantations are to be ascribed to the effect of coal-smoke pollution during the past century. However, the elucidation of the factors bringing about deterioration and even death is difficult since the production of smoke is matched by an increased need for timber, leading to preferential cutting, as well as, more recently, preferential selection of species. A physical basis of measurement of some of the common pollutants is desirable only in so far as biological assays are hedged with difficulties as to interpretation.

The stimulus for the investigation of country levels of pollution is provided by the need to afforest difficult sites on both sides of the Pennines on inhospitable soils exposed to a dull and harsh climate, where the choice of economic species is in any case restricted. The disentangling of pollution/exposure and pollution/fertility interactions (if either be possible) is the prime need. In the first place, Forestry Commission research has begun with the assessment of sulphur dioxide by the lead peroxide method. Similar levels indicated by this technique give no assurance that solid deposits will follow similar trends, and the variation in the ratio of water-soluble to insoluble matter collected in deposit gauges indicates the wide range of types of emission, as well as of the history of that emission. The disadvantages of the lead peroxide method may be in its manner of integration, so that in the absence of other observations a particularly highly concentrated visitation at a time of high plant susceptibility may pass undetected.

More fundamental is the question of the effect of prevalent high wind velocities on the rate of formation of sulphate. Two examples, one of moor top as opposed to valley stations in open country, the other of a gauge sheltered by a wood and contrasted with gauges on either side of the wood, suggest discrepancies which may not in fact reflect true differences of sulphur dioxide concentration. Fumigation experiments with sulphur dioxide, often of short duration, have usually been carried out in the past with concentrations of 1–100 times those averaged over a month occurring naturally, though occasionally concentrations in Nature may increase to the higher levels used in fumigation experiments. Mr. Grayson suggested that apart from species (and possibly strain), concentration, and period of fumigation, different ages of plant or plant organs should be treated in fumigation experiments, since field-observation suggests that atmospheric pollution effects are often most noticeable in trees after the grand period of height growth is finished.

A paper prepared by Dr. G. Scurfield (at present with the Commonwealth Scientific and Industrial Research Organization, Canberra) was read by the chairman, Mr. M. V. Laurie. Dr. Scurfield began by asking three questions: (i) Is there unequivocal proof that pollution effects are operating to reduce timber yield on certain sites? (ii) Given such sites, can we designate the pollutants causing the reduction in yield and, if so, can we define an upper permissible limit of concentration for the pollutants concerned? (iii) Given such pollutants, in what ways do they interfere with the developmental processes of the tree so as to cause a reduction in yield?

Observations of decline in vigour of tree growth from cities tend to support the contention that the effects of general pollution are cumulative and need not be accompanied by the production of visible leaf lesions. Many such observations are concerned with effects produced by 'general' atmospheric pollution after the contaminants have undergone considerable dilution and probably interaction. The effects produced by temporary and usually local increases are more certain, and have in a number of cases been checked by means of fumigation experiments. Field-symptoms have been also duplicated in experimen with hydrogen fluoride where this agent has bee suspected.

The different levels of pollution which evergree and deciduous species have to endure are brougl out in the typical annual sine curve of sulphu dioxide and smoke (which is of great chemical con plexity, but which contains a number of oth contaminants) in the vicinity of urban areas. Tl cumulative effect of a number of pollution cycles probably to reduce growth indirectly by acceleratin leaf abscission. Experiments to determine toleranc in known environmental conditions might be carrie out on the following bases: (i) using transplants the same soil but different pollution regimes, alon side meteorological stations so that any micr climatic differences between sites could be assessed indicator species (for which damage symptoms f specific pollutants have already been assessed) migh also be included; (ii) using growth chambers throug which 'screened' air could be passed, so that speci agents responsible for reduction in growth wou eventually be determined. Lastly, by using 'phyt tron' techniques, tolerances to combinations of tl variables might be determined. Such techniqu could also be used to assess the indirect effect soil fertility.

In answer to the second question posed, D Scurfield emphasized how necessary it is to avo the tendency to regard sulphur dioxide as the so gaseous pollutant. In addition to thirty gases liste by the Alkali, etc., Works Registration Act, 190 recent analyses have shown hitherto unsuspecte contaminants. Further, there are the chemical physical processes occurring after emission; f example, the reaction products of ozone and certa hydrocarbons. Radioactive isotopes, also, should n be ignored altogether. The permissible concentratio allowed to pass to the air are, so far as sylvicultu is concerned, largely arbitrary. Upper limits tolerance will wait on results through the specie ontogeny and under known conditions. When the are known, concentration limits must be reassess in relation to topography and atmospheric co ditions. Where inversions are liable to occur, f example, the ideal solution would be the regulati of rates of emission in accordance with the diffusi properties of the atmosphere at the time. Th thorough evaluation of sites from a meteorologic and atmospheric pollution point of view shou preferably be undertaken before planting.

Thirdly, with regard to the physiological pr cesses concerned, it may be said that the mo prominent effect of 'general pollution' is to cau premature leaf abscission. Organic sulphur con pounds may play some part in these phenomen Though abscission may not always be due to t same agent, some mitigation might be obtained l treatment with compounds so affecting auxin activi as to retard abscission. Effective elimination harmful sources will only be undertaken, said D Scurfield, if we emphasize the effects and if we ca point to the agents responsible.

Finally, Dr. P. F. Wareing (University of Ma chester), who explained that he was in part deputizi for Dr. J. K. A. Bleasdale, whose thesis on the decli of certain leys in the hill pastures of East Lancashi had shown valuable results, and for Dr. Scurfiel who had also worked at Manchester, proceeded amplify and clarify many of the points mentioned previous papers. In discussing what is the importa pollution factor, he pointed out that while good grounds exist for considering sulphur dioxide the main injurious agent, we have not yet determined that some of the accompanying products of coal combustion may not bring about injuries, such as have been described for pollutants resulting from the combustion of petroleum in Los Angeles. The work on fumigation with sulphur dioxide in greenhouse experiments involves only relatively short-term experiments at high concentrations. This provides no real simulation of the processes occurring in Nature. Dr. Wareing also stressed the fact that the most susceptible parts of plants are the leaves, so that evergreens, which retain their leaves during the winter when pollution is usually at the highest levels, are generally less resistant than deciduous species. Nevertheless, other factors must be of importance, since there are marked differences as between different species both among evergreen and deciduous plants.

Further elucidation was provided by Dr. Wareing in the discussion which followed. Mr. M. V. Edwards (Forestry Commission) brought matters down to earth in referring to the effects visible on some of the high upland plantations. Here similar symptoms of damage are noticeable on young trees where they are seriously exposed to 'clean' winds and those exposed on the South Pennines to smoke-laden winds. The design of experiments required to isolate the factors of pollution and exposure meets with very serious difficulties. The provision of shelter, for example, automatically means the bringing into existence of a different pollution regime. Mr. A. Bleasdale (Meteorological Office) said that if foresters working in this field need help from meteorologists, then they should be as detailed as possible in stating their requirements so that records could be used most effectively.

Both this discussion and the papers point to the great need for study of the cumulative effects in sylviculture of pollution, in addition to the determination of the toxic concentrations of individual contaminants and combinations of pollutants under known conditions.

A. J. GRAYSON

RESPIRATORY PIGMENTS

IN opening a discussion on "Respiratory Pigments" arranged by Sections D (Zoology), H (Anthropology) and I (Physiology) at the Sheffield meeting of the British Association, Prof. F. J. W. Roughton reminded his audience that eight years had passed since the Barcroft Memorial Conference on hæmoglobin had met at Cambridge, and said that they had been years of rapid progress, some of it stimulated by that Conference. In the discussion three groups interested in hæmoglobin were all represented: they were physiologists, who are concerned with its role in promoting gas exchanges in the animal body, biochemists interested in the mechanism and physical chemistry of the gas reactions, and biophysicists who find it an easily available and readily crystallized material already carefully studied and characterized physiologically.

The first paper, by Profs. Q. H. Gibson and F. J. W. Roughton, was concerned with the thoroughgoing application of Adair's intermediate-compound hypothesis to the equilibria and kinetics of the reactions of hæmoglobin with gases. Adair's original paper, published thirty-one years ago, suggested that combination of each hæmoglobin molecule with four molecules of gas takes place in four distinct stages, one gas molecule combining at a time to yield separate molecular species containing one, two, three or four gas molecules.

The general acceptance of Adair's hypothesis has been delayed by the failure of attempts to demonstrate the intermediate compounds spectroscopically, and because the equation giving the relation between oxygen tension and percentage saturation arising from the intermediate-compound hypothesis contains four constants—enough to allow any ordinary experimental equilibrium curve to be fitted within 0·5–1 per cent saturation by several sets of constants with widely differing values.

In recent years, Roughton and his co-workers at Cambridge have overcome the second difficulty by refining the methods used for determining the dissociation curve and extending them to the ranges 0–1 per cent and 98–100 per cent saturation, so that only one set of constants can be found to fit the experimental results. This work has shown that, for sheep hæmoglobin, there is a great increase in affinity for oxygen after three molecules have combined, the affinity for the fourth molecule being, at pH 9·1, 280 times greater than that for the first.

The kinetic work described in the same paper is an example of co-operative research carried on by several groups of workers. The problem was to determine numerical values of the four combination velocity constants for the reaction of reduced hæmoglobin with carbon monoxide. The experimental material, records of the change in concentration of reduced hæmoglobin with time, was obtained by the stopped-flow photo-electronic method, in Sheffield. The percentage saturation was found to within 0·5 per cent during the period from 5 to 100 msec. after bringing the reactants together, using a photomultiplier and cathode-ray oscillograph to follow the reaction. The results were then compared, by Dr. H. E. Daniels, of the Cambridge Statistical Laboratory, with solutions of the differential equations describing the reaction. These solutions were computed by the EDSAC electronic machine in the Cambridge Mathematical Laboratory. In this way the values of the individual velocity constants for the combination of successive carbon monoxide molecules were found, together with their standard errors. Here again, with sheep hæmoglobin at pH 9·1, it was found that a great increase in combination velocity took place after three molecules of carbon monoxide had combined, the fourth molecule combining some sixty to eighty times faster than the first.

Although the new results have allowed the unequivocal application of the intermediate-compound hypothesis to one kinetic case, much remains to be done, especially to extend the analysis to the physiologically interesting case of combination with oxygen, though the formidable difficulties of reckoning with eight independent kinetic constants may well delay a solution for some time.

Dr. V. M. Ingram followed with an account of recent progress in research on the structure of hæmoglobin by X-ray methods. The present position is that while projections of the molecule are available which tell us how much material lies in the line of sight in a given direction, more detailed information can only be obtained by making projections of thin slices of the molecule.

Certain specific groups have, however, been located by labelling them with heavy-metal atoms which show up on X-ray diffraction analysis. It has been found, in this way, that the —SH groups of horse hæmoglobin are arranged in close pairs. As Riggs in the United States has recently shown that the —SH and hæm groups have a close functional relationship, it is not impossible that they may be close to one another in the molecule.

Very recently a striking new advance has been made in the study of sickle-cell anæmia. In this condition the hæmoglobin differs from normal in the number of its —SH groups, its solubility and in the remarkable property of forming a gel on reduction. Dr. Ingram has now found, using a combination of paper chromatography and paper electrophoresis, that a peptide appears regularly among the products of tryptic hydrolysis of sickle-cell hæmoglobin which is not present in similar hydrolysates prepared from normal human hæmoglobin. As sickle-cell anæmia is the result of change in a single gene and is inherited in a strict Mendelian way, the possibilities of an increase in our understanding of the relation between genes and proteins synthesis are obvious.

After an interval, Prof. Q. H. Gibson described some applications of flash photolysis to the study of hæmoglobin kinetics. The observations, so far, have been made with a simple apparatus in which the solution to be examined is exposed to the photolysis flash in an integrating sphere and the changes in light absorption are recorded by means of a continuous light source, photocell, and cathode-ray oscillograph. The systems studied are arranged so that at equilibrium the chief compound present is carboxyhæmoglobin, which, as is well known, is sensitive to light. On firing the photolysis flash, this carboxyhæmoglobin is caused to dissociate, setting free reduced hæmoglobin. After the flash ends, the recombination of the reduced hæmoglobin with carbon monoxide or with other ligands forming compounds less stable than carboxyhæmoglobin can be studied.

One application of the method has led to a dramatic confirmation of the difference in kinetic properties between the different intermediate compounds of carbon monoxide with hæmoglobin. By reducing the power of the photolysis flash, partially saturated intermediates can be formed in the solution in calculable quantities. It is found that when large proportions of the intermediate $Hb_4(CO)_3$ are formed, the recombination reaction involving the addition of the fourth and last molecule of carbon monoxide to combine takes place up to sixty times faster than when only fully reduced hæmoglobin is present. It is satisfactory that such good agreement can be reported between the widely different approaches to the kinetic problem described at this meeting, since this rapid reaction was predicted from measurements of the upper end of the dissociation curve and the velocity of dissociation of the first molecule of carbon monoxide from fully saturated hæmoglobin.

Another application reported was to the study of hæmoglobins from invertebrates. Here the advantage of the flash method is its economy in material. This economy must now be approaching its highest possible degree, since the same material can be used repeatedly in duplicate experiments or in runs under altered conditions. It is interesting to reflect that in the thirty-three years since Hartridge and Roughton made the first measurements of the reaction velocity of hæmoglobin with gases, the pigment requirements have been reduced some 100,000 times. It is now readily possible to examine the hæmoglobin from a single specimen of *Arenicola*, say, or of *Chironomus*, but it would seem that several specimens of *Daphnia* would still be needed.

In the final paper of the meeting, Prof. F. J. W. Roughton described the application of some of the kinetic work to the problems of passage of gases from the alveoli into combination with the hæmoglobin. This process, at first sight deceptively simple, must in fact be split up into a number of component steps, each of which plays its part in determining the rate of the overall process. The gas molecules concerned must first diffuse through the alveolar membrane, then through the plasma to the erythrocyte, through the cell membrane of the latter, and finally through the interior of the cell until they meet a hæmoglobin molecule with a vacant gas-binding group.

It has now been possible to evaluate the importance of each of these factors in contributing to the final physiological result. It has been found that the resistance of the alveolar membrane and the resistance in the erythrocyte contribute about equally to the difficulty met with in the uptake of carbon monoxide or oxygen from the alveoli into combination with hæmoglobin. In the erythrocyte, the chemical combination reactions with oxygen and nitric oxide are so rapid that the actual rate of gas uptake is determined primarily by the rate of diffusion through the red-cell membrane and the interior of the cell modified only slightly by the rate of the chemical reaction. With the slower reaction of the displacement of oxygen by carbon monoxide, the rate of the chemical reaction already plays an important part; and when we come to consider the dissociation of carboxyhæmoglobin the picture is reversed, the chief rate-limiting factor now being the chemical reaction which is slow as compared with the rates of diffusion in the blood and across the membranes.

The new quantitative descriptions of the exchange processes in the blood and lungs have been applied to determine anew the diffusing capacity of the lung membranes and the volume of blood in the lung capillaries. The greater certainty about these processes should lead to advances in fields as diverse as clinical medicine, long-distance running, and in knowledge of how life is carried on at high altitudes.

OBITUARIES

Prof. Carl Neuberg

On May 30 Prof. Carl Neuberg died in New York at the age of seventy-nine. With Neuberg's death ended a succession of brilliant German organic chemists, born and trained in the last century and devoting their life-work mainly to the application of newly developed chemical methods to the study of the components of living matter, their composition, structure and metabolic changes; among them were Friedrich Wöhler, Justus v. Liebig, Felix Hoppe-Seyler, Adolf v. Bayer, Albrecht Kossel, Emil Fischer, Franz Hofmeister and Richard Willstätter.

Equipped with a broad knowledge of, and deep insight into, organic chemistry, possessed by a passionate interest in the material changes of living matter and endowed with a rare skill for devising methods suitable to a direct approach to the problem, Neuberg was one of the founders of modern biochemistry.

Born on July 29, 1877, at Hannover (Germany), he received his scientific training in the Universities of Berlin and Würzburg. In 1898 he joined E. Salkowski in the Chemical Division of the Pathological Department of the University of Berlin; in 1909 he was appointed head of the Chemical Unit of the Department of Animal Physiology at the Agricultural College, Berlin, and in 1913 he became assistant director of the Kaiser Wilhelm Institute for Experimental Therapy under August v. Wassermann, whom he succeeded in 1925. The Institute became one of the foremost centres of biochemical research. Although Neuberg had given signal service to his native country both in peace and in the First World War, he was forced by the Hitler regime to leave it in 1939. He found refuge in the United States, where he was at first research professor at the College of Arts and Sciences of New York University and then professor at the Brooklyn Polytechnic Institute and at the New York Medical College.

Neuberg's main contribution to science was the elucidation of the principal mechanism underlying alcoholic fermentation of sugar by yeast. This process, though the subject of violent controversy between the most illustrious chemists of the last century, remained an unsolved mystery until Harden and Young in London and the Neuberg school at Berlin entered the field. The first step in unravelling the integrated series of reactions by which the carbon chain of the sugar molecule is disrupted was the demonstration that pyruvic acid is readily and quantitatively transformed to carbon dioxide and acetaldehyde by a yeast enzyme named carboxylase. The next step was the trapping by sodium sulphite of the intermediary acetaldehyde in the course of glucose fermentation. The hydrogen becoming available through the formation of the carboxyl group of pyruvic acid, but deprived of its physiological acceptor acetaldehyde, was traced in glycerol, produced in stoichiometric quantity to the trapped acetaldehyde. The interpretation of these findings was given by Neuberg in a fermentation scheme the main features of which were: (1) dehydration and de-aldolization of one mole D-glucose to two moles of a 3-C-aldehyde assumed to be methylglyoxal, (2) oxidation of the ketoaldehyde to pyruvic acid, and (3) reduction of the decarboxylated pyruvic acid to alcohol.

The concept of alcoholic fermentation as the balanced sequence of an energy-yielding dehydrogenase reaction and a reaction in which a hydrogen acceptor derived from the first reaction combines with the hydrogen atoms released proved to be one of the most fruitful theories in the realm of fermentation and respiration. Neuberg demonstrated clearly that the end-products of sugar fermentation by yeast vary with the nature of the hydrogen-accepting system available. The ideal fermentation equation of Gay–Lussac is never verified because yeast on metabolizing sugar forms a variety of competing hydrogen-acceptors, their quality and quantity depending on the conditions imposed. Neuberg realized the key position of pyruvic acid in the metabolism of fungi and bacteria and ascribed the great diversity of products formed in the various types of fermentation mainly to the formation of a wide range of hydrogen-acceptors from pyruvic acid. It may be said with confidence that the production of pyruvic acid, isolated in high yield from fermenting sugar solutions by Neuberg in 1929, is the central stage of a carbohydrate degradation pathway very common in living cells; this central stage is preceded by phosphorylating and desmolatic steps and followed in respiration by the Krebs cycle, in fermentation (glycolysis) by reduction of pyruvic acid or a derivative thereof.

In addition to carboxylase, Neuberg discovered the enzymes β-glucuronidase, methylglyoxalase, phenolsulphatase, chondrosulphatase, polyphosphatase and metaphosphatase. His wide interest and experimental skill are documented by many other notable achievements. Among them are studies on the structures of raffinose, inositol and phytin, first non-enzymatic preparation of phosphorylated sugars and amino-acids, discovery of fructose-6-phosphate (Neuberg ester), first observation of the carboligatic reaction and synthesis of the various phosphoglyceric acids.

Neuberg's work has done much to shape present trends in biochemistry and his contributions to knowledge will long be remembered. In 1906 he founded the *Biochemische Zeitschrift* and edited no less than 278 volumes in the next thirty years. Among the many honours bestowed upon him were the Emil Fischer, Delbrück, Pasteur, Berzelius, Scheele and Leblanc Medals, and the Carl Neuberg Medal established by the American Society of European Chemists and Pharmacists in 1950. He received several honorary degrees, and was a member of many scientific academies. Of Neuberg may be said what he himself said at the funeral of his predecessor A. v. Wassermann in 1925: "He belonged to the small band of scientists who visibly moved the hand of the clock recording the advancement of science".

ALFRED GOTTSCHALK

Dr. Gunnar Dahlberg

DR. GUNNAR DAHLBERG, who died on July 25, was born in Lofta, Sweden, in 1893 and was educated in the University of Upsala, graduating M.D. in 1926. It was in Upsala where his career was spent, for he was director of the Statens Rasbiologiska Institut there from 1936 until his death. He was also dean of the Faculty of Medicine at Upsala during the critical year 1939–40 when Swedish mobilization faced the University with administrative problems, into which he threw his energies with enthusiasm as one of the leading Swedish intellectuals with uncompromising hostility to the Nazi challenge. From the start a vigorous critic of the Nazi creed, he was at all times a friend of the British cause when the Second World War became inevitable. In 1948 he received from Britain the King's Medal for Service in the Cause of Freedom in recognition of the part he played.

As a man of science, Dahlberg is remembered for his early work on twin resemblance, his pioneer publications on the genetical theory of inbreeding and more especially for his concept of the population isolate. Above all, he strove to develop human genetics as a branch of medical science dissociated from its discreditable associations with racialist propaganda. He edited a monumental semi-popular encyclopædia sponsored by the Swedish Red Cross Society. He was the author of an important book on vital statistics, "Sjukdomarna och Samhällhet", and also a popular book translated by Lancelot Hogben under the title "Race, Reason and Rubbish". In 1953 the *Acta Genetica et Statistica Medica* celebrated his sixtieth birthday by publishing a memorial volume to its editor.

Among Dahlberg's many honours were an honorary LL.D. of Aberdeen (1938) and a doctorate of odontology (*honoris causa*) of Stockholm (1955). He received the Alvarenga Prize of the Swedish Medical Association in 1929 and a prize award in 1933 from the King Oscar II Jubilee Fund. He is survived by his widow Stina (*née* Westberg), whom he married in 1919.

NEWS and VIEWS

Mathematics at the Imperial College, London: Dr. Abdus Salam

Dr. Abdus Salam, lecturer in the University of Cambridge, has been appointed to a University chair of mathematics at the Imperial College of Science and Technology, London. Dr. Salam is a brilliant mathematician with an international reputation in the field of theoretical physics. He has played an important part in the development of quantum electrodynamics and the various theories which have been formulated to interpret the properties of mesons and other recently discovered fundamental particles. His activities in these directions will be especially appreciated at Imperial College, where he will find colleagues with an active interest in the experimental side of such investigations. Dr. Salam received his early education at the University of the Punjab, where he took the M.A. degree in 1946. In 1948 he graduated at Cambridge and was awarded the Ph.D. degree of that University in 1951. In the same year he was elected to a research fellowship at St. John's College, Cambridge. Dr. Salam has previously held high appointments in mathematics. In 1951 he became professor of mathematics at Government College, Lahore, and in 1952 was appointed head of the Department of Mathematics in the University of the Punjab. Since 1954 he has been a lecturer in the University of Cambridge and acted as scientific secretary at the Geneva Conference in 1955 on the peaceful uses of atomic energy.

With the appointment of Prof. Salam, there are now four professors in the Department of Mathematics in the Imperial College, namely: Prof. H. Jones, who is the head of the Department; Prof. G. A. Barnard, professor of statistics; Prof. W. K. Hayman, professor of pure mathematics; and Prof. A. Salam, who will be concerned mainly with applied mathematics and mathematical physics.

Pan-American Foot-and-Mouth Disease Centre, Rio de Janeiro: Dr. W. M. Henderson

Dr. W. M. Henderson, deputy director of the Research Institute (Animal Virus Diseases), Pirbright, Surrey, has been appointed director of the Pan-American Foot-and-Mouth Disease Centre, Rio de Janeiro, Brazil, and is taking up his duties in January. This international centre began in 1951 as a Technical Co-operation Project of the Organization of American States. The operation of the Centre is the responsibility of the Pan-American Sanitary Bureau, which is the regional office of the World Health Organization. The work of the Centre is the training of national laboratory and field staffs responsible for the control of foot-and-mouth disease in the Americas, the provision of a field consultation and confirmatory diagnostic service and research. It is now intended to expand the research facilities and activities.

Dr. Henderson, who is forty-three, was educated at the Royal (Dick) Veterinary College and the University of Edinburgh and qualified in 1935. During 1936–39 he was assistant to Prof. George F. Boddie, professor of medicine in the Royal (Dick) Veterinary College, Edinburgh. In January 1939 he was appointed research officer to the Pirbright Research Institute to work on foot-and-mouth disease and other vesicular diseases of animals. When the post of deputy-director was created in 1955, his abilities were recognized by his selection for the post. During his seventeen years at the Institute, Dr. Henderson has made outstanding contributions to the advancement of knowledge on foot-and-mouth disease. He has been responsible for developing new methods which are now recognized as standard procedures for research on the disease and for the control of the preparation of vaccines. He was awarded the degree of D.Sc. of the University of Edinburgh for a thesis on the "Quantitative Study of Foot-and-Mouth Disease"; and the method of virus estimation with which this deals is now known as Henderson's method and is widely used in many research institutes.

First Companion Members of the Textile Institute

Under by-laws authorized by the supplemental royal charter granted to it last year, the Textile Institute is empowered to elect as companion members (Comp.T.I.) those of its members who in the opinion of the Council have substantially advanced the general interests of the textile industry. The Council has announced the first conferment of this honour to the following seven members, who will be formally admitted by the President at the Institute's convocation in Manchester on October 26: Mr. James Ewing, chairman and joint managing director of the Bradford Dyers' Association, Ltd.; Sir Ernest Goodale, chairman and managing director of Warner and Sons, Ltd., London, and past president of the Institute; Mr. H. G. Greg, chairman of R. Greg and Co., Ltd., Reddish; Sir John Hanbury-Williams, chairman of Courtaulds, Ltd.; Mr. J. A. Nasmith, vice-president of the Universal Winding Co., and a former chairman of Council of the Institute; Mr. S. F. Peshall, of N. Corah and Sons, Ltd., Leicester; and Sir Raymond Streat, chairman of the Cotton Board and past president of the Institute.

The Realm of the Nebulæ

It was the astronomer Edwin Hubble who said that the history of astronomy was a history of receding horizons. While research at the limit of distance remains as important as ever, developments during the past two decades have emphasized the necessity of studying the physical nature of the extragalactic nebulæ as well as their motions and distribution. This is exemplified by the articles in the September 1956 issue of the *Scientific American*, he whole of which is devoted to astronomy as elated to cosmology. The fundamental discovery of he two stellar populations has shed light on the volutionary history of a galaxy, and this has been einforced by studies of the origin of the chemical lements and of the nuclear processes which take lace in stars. Astronomers are now aware of the asic nature of interstellar material as the source of he bright stars of Population I, and when a collision f galaxies occurs the interstellar matter which they ontain is the seat of the optical and radio emissions hich are observed. A decision between evolutionary nd steady-state cosmologies is much to be desired; easurement of the red-shifts of more distant ebulæ, identification of additional distant colliding alaxies as radio sources, further investigations on he large-scale distribution of galaxies, all may ontribute to the decision. Observational programmes now in progress may indeed provide the ssential data for the solution of the cosmological roblem.

ccultations of Radio Sources by the Moon

A PAPER, by F. Link, entitled "Occultations des Radiosources par la Lune et Phénomènes Connexes" *Bull. Astro. Instit. Czechoslovakia*, 7, No. 1; 1956), eals with the possibility of occultations by the Moon f radio sources and shows the existence of a very arified lunar atmosphere. In an earlier publication 5, 112; 1954) Link directed attention to a series of uch occultations between the years 1955 and 1957, nd C. L. Seeger has also directed attention to the ame subject (*Trans. Int. Astro. Union*, 8; 1952). he investigation has more than an academic interest, nd Link refers to four matters which are of great nterest and importance: the exact determination of he positions of radio sources; the determination of he photometric profile of radio sources; the disovery of new feeble radio sources; and possible roofs of the lunar ionosphere. As the last-mentioned an modify the interpretation of the first three oints, it is dealt with first in the paper. Link oints out that different attempts based on the ptical properties of the lunar atmosphere have not o far led to definite results. Lyot and Dollfus, by easuring with the coronagraph the brightness in the icinity of the Moon's horns at the first quarter, stimated the superior limit of the density relative o that of the Earth's atmosphere at sea-level as 10^{-8} pproximately. Dollfus, continuing with the investiations and basing his research on the polarization f the light diffused by the hypothetical atmosphere f the Moon, obtained a limit of about 10^{-9}, while Kuiper, using the spectroscopic method to detect races of sulphur dioxide, gave the mass of a vertical olumn of this gas the upper limit 3×10^{-10} that of he terrestrial atmosphere. Other attempts by Lyot nd Dollfus by the method previously described did ot give such low limits. Link investigates the ubject, starting with the two factors that determine he existence of any ionosphere—terrestrial or lunar; hese are the presence of gases capable of being onized, and the ionizing solar radiation. Examining hese two factors on the Earth and on the Moon, his athematical investigations lead to the suggestion hat a lunar atmosphere of density 10^{-12} that of the errestrial atmosphere at sea-level might give observble phenomena such as the deviation of the rays nd the augmentation of their intensity. It is dmitted at the end of the paper that it is premature t present to pursue these general considerations, their aim being merely to direct attention to occultations of radio sources and the phenomena which can accompany them.

Water Resources of Great Britain

THE problem of water conservation and flood control in Britain is receiving increasing attention by the authorities concerned (see *Nature*, **176**, 1133; 1955) and, in particular, has become more widely recognized during the present year as a result of the contrasts of water shortage during a dry winter and much recurrent flooding in the course of a wet summer. The publication of the "Surface Water Year-Book of Great Britain, 1953–54" (pp. 117. London: H.M.S.O., 1956; 30*s*. net) is a welcome reminder of the work now in hand to assess the water resources of the country on a more scientific basis. This publication of the Ministry of Housing and Local Government and of the Scottish Office gives hydrographic statistics for British rivers, together with related rainfalls, for the year ended September 30, 1954, and is the first of the intended yearly issues covering periods of one water year. The two previous publications embraced eight years each, and the records were somewhat patchy and broken. The new annual issue will, it is hoped, ensure both uniformity and continuity. The new volume contains the flow records of a hundred and two stations, has the daily discharges of most, and includes discharge frequencies for certain selected stations. A new feature is the inclusion of natural water temperatures of the River Test in Hampshire and the River Avon in Somerset. It is hoped to extend these observations into a network of temperature-recording stations which will eventually provide standards of comparison to which intermediate observations, in place or time, may be related.

Standard Capacitors and their Accuracy in Practice

No. 13 in the series of "Notes on Applied Science" of the National Physical Laboratory, Teddington, which is on "Standard Capacitors and their Accuracy in Practice" (pp. 10. London: H.M.S.O., 1955; 1*s*. 3*d*. net), directs attention to the various factors which affect the performance of capacitors, both by virtue of their construction and by their method of use. The booklet is primarily concerned with capacitors designed for use as laboratory standards, and the information given is based on the wide experience gained in testing and using such instruments over many years at the Laboratory. Both air-dielectric and solid-dielectric capacitors are discussed, and separate sections deal with the inductance and resistance of capacitors and with the effects of leads on the measured values of the capacitances. Good-quality capacitors, whether with air or mica dielectric, it is concluded, provide a standard of reactance not greatly inferior in constancy to that of a good resistor, provided that proper precautions are taken in their maintenance and use. Clamped mica capacitors of between 0·1 and 1 μF. are probably the most stable, and if they are kept under moderate and uniform conditions of temperature and humidity the fluctuations about their mean values should not be more than ± 0·5 part in 10^4 on capacitance and ± 20 per cent on power factor, over a period of several years. The capacitance of a capacitor of simple geometric shape can be calculated from its linear dimensions and from the dielectric constant of the material between its electrodes, and thus in theory it should be possible to make an absolute standard of capacitance against which all other capacitors can be compared. However, absolute standards of inductance can be designed and constructed with considerably greater accuracy, and measurements of capacitance are ultimately based, in conjunction with a frequency standard, on the Campbell standard of mutual inductance which is the absolute standard of reactance at the Laboratory.

Catalogue of Nuclear Reactors

THE Chalk River Project of Atomic Energy of Canada, Ltd., with the co-operation of the Atomic Energy Research Establishment, Harwell, has prepared a "Catalogue of Nuclear Reactors 1955" (AECL No. 220; CRR-590. Pp. 60. London: H.M.S.O., 1955; 4s. 6d. net), which has been compiled from the unclassified literature and refers to reactors that are known to have reached criticality by July 1955. The catalogue includes reactors in Canada, France, Great Britain (BEPO, DIMPLE, GLEEP and ZEPHYR at Harwell and the two reactors at Windscale), Norway, Sweden, Switzerland, the United States (about forty reactors, including six at Arco, Idaho, and nine at Hanford, Washington) and the U.S.S.R. The details given for each reactor consist of brief notes covering six items—neutron speed; fuel configuration; kind of moderator; purpose (research, power, etc.); thermal power; and neutron flux—as well as constructional details and one or two useful references. Additions to, and revisions of, the catalogue will be prepared from time to time in order to keep the collection of data up to date.

Chemistry Films

A SPECIAL issue of the *Scientific Film Review* catalogues films on chemistry and allied topics (2, No. 2; June 1956). The list is derived from one compiled by the Scientific Film Association in 1949 and includes the appraisals then prepared by the Association's viewing committee. To the appraisals have been added films from many recent catalogues, one or two reviews and some foreign films. For the catalogue, chemistry has been widely interpreted so that no known film likely to be of use has been omitted. Among the sections for which films are included are agriculture, atomic physics, crystallography, laboratory techniques, industrial manufacturing processes, microscopy and public health.

International Abstracts of Biological Sciences

THE Council of Biological and Medical Abstracts, Ltd., has decided to change the title of its journal *British Abstracts of Medical Sciences* to *International Abstracts of Biological Sciences*. This decision has been brought about, first, by an extension of the scope of the *Abstracts* to a wider range of biological research subjects published in journals throughout the world, and, second, by the fact that the *International Abstracts of Biological Sciences*, with the co-operation of the specialist editors selected by the Institute of Scientific Information of the Academy of Sciences of the U.S.S.R., will include, as from the January 1957 issue, translations of important Russian papers abstracted in the *Referativny Zhurnal Biologii* (Soviet biological abstracts) and *Referativny Zhurnal Biologischekoi Khimii* (Soviet abstracts of biological chemistry), to be published simultaneously with their appearance in Russian. The *Abstracts* are published for the Council of Biological and Medica Abstracts, Ltd., by the Pergamon Press, of London and New York, on a non-profit-making basis, and the honorary editor is Dr. C. C. N. Vass. Since the Russian abstracts will have to be translated, the Council requires translators with knowledge o anatomy, animal behaviour, biochemistry, endocrinology, experimental biology, experimental medicine, microbiology, odontology, pathology, pharmacology and physiology, and would welcome offers o help. Terms of payment and other details can be obtained from Dr. C. C. N. Vass, c/o Pergamon Press Ltd., 4–5 Fitzroy Square, London, W.1, or 122 Eas 55th Street, New York 22, N.Y.

Political and Economic Planning

IN Broadsheet No. 400, entitled "PEP 1931–56" (*Planning*, 22, 141; July 23, 1956; 2s. 6d.), Politica and Economic Planning explains its purpose and methods of working, emphasizing particularly the dependence of its success on the anonymity of the groups and the insistence on the importance and nature of research in relation to public affairs. For each study it has brought together both experts skilled in various aspects of the subject under study and laymen chosen for their ability to ask the necessary questions and to hold the balance between conflicting specialists whenever necessary. For the most part, PEP has concentrated on research into the results of available research and into material and experience already gathered for other purposes, except where first-hand sample investigations have been essential. For the past two years, PEP has been engaged on two projects financed under the Conditional Aid Scheme for the Use of Counterpart Funds derived from United States economic aid. A report on the first, which will provide accounts of the work of particular trade associations and their relation with individual firms and public corporations, is due for publication later this year. The second consists of a survey of the employment entered by men graduating in a selected year, 1950, which is also to be published this autumn under the title "Graduate Employment", and a survey of the policy and practice of industrial undertakings in employing graduates. PEP is also engaged on two other major studies: one, expected to take three years, on adaptation in industry; and the other on family needs and the social services. The present broadsheet suggests that the fundamental strength of Political and Economic Planning is in its intellectua initiative and possession of the necessary qualities and resources to continue pioneering new fields and new techniques; but the report emphasizes the need for regular income and for more subsidies if the volume and quality of the work are to be maintained.

Training for Supervisors

"IF we are going to be really effective in world competition, then we must make for greater efficiency, and one of the ways of doing so is by having bette supervision." These are among the concluding words of a discussion between five people from different spheres of industrial life recorded in a booklet called "Training for Supervisors" which has been issued by the Ministry of Labour and Nationa Service. The five people—a training officer, genera manager, director, production superintendent and shop foreman—met to express their views on the conclusions of the 1954 Report of the Committee of Inquiry on the Training of Supervisors and relate these conclusions to their own experience in industry.

The group was in general agreement on three points. First, that the responsibility for training supervisors is one for senior management; second, that industrial training is ineffective if it is of a purely academic character; and third, it is no good giving the supervisor training if his status is not right in the firm. He must be regarded as a member of the management team. The booklet has been prepared in collaboration with the Central Office of Information and with the aid of a grant made available under the Conditional Aid Scheme for the Use of Counterpart Funds derived from United States economic aid. It is not for sale; but copies can be obtained on request from the Director of Public Relations, Ministry of Labour and National Service, 8 St. James's Square, London, S.W.1. The other booklets in the series deal with joint consultation in industry, the spreading of information in the factory and personnel selection.

Scientific Research at South African Universities during 1955

The fourth volume of the "Register of Current Scientific Research at South African Universities" covers research conducted during 1955 (pp. 341. Pretoria: Council for Scientific and Industrial Research). The investigations described are arranged under the name of the university department concerned, which is listed alphabetically according to its English name, with occasional subject cross-references. The actual information is given in the language in which it was received from the universities; but headings and sub-headings are in English only, and this year an English translation of the subject of research submitted in Afrikaans is included. Agricultural chemistry and agricultural engineering are indexed as sub-sections of agriculture, and all chemistry entries are entered under the one general heading of chemistry (inorganic, organic and physical). Academic degrees and full professional qualifications are given where these are ascertainable. The volume contains 545 entries.

Royal Scottish Museum, Edinburgh: Report for 1955

The annual report for 1955 of the Royal Scottish Museum, Edinburgh (pp. 16; from the Museum; 1956), is a record of steady progress, especially in the related work carried out for cultural and educational institutions. Following the example of the director, Dr. D. A. Allan, who has contacts both at national and international levels, members of the senior staff have made many personal contributions to a wide variety of educational and cultural organizations in the field of museum work. It is unfortunate that the long-needed lecture hall is still in the drawing-board stage.

Government Museum, Madras: Report for 1954–55

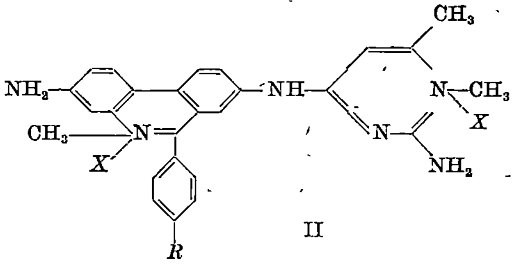
The annual report of the Government Museum, Madras, for 1954–55 (pp. 46+2 plates. Madras: Government Press, 1956) records the excellent educational work which is being undertaken by this progressive institution. Certain students in the University of Baroda have been given detailed instructions in museum methods, while other students of the University of Madras were provided with practical demonstrations in anthropology. Despite a limited staff, much preservation work has been carried out, especially in the chemical conservation section, where experiments were made concerning the electrolytic method for cleaning coins.

French Metallurgical Society

The French Metallurgical Society will hold its autumn meeting in Paris at the Maison de la Chimie during October 22–27. At the meeting the following awards will be presented: the Grand Medal of the Society, to Prof. R. F. Mehl for his work, in general, on metallurgy; the Sainte-Claire-Deville Medal, to R. Gadeau for his work on aluminium of high purity; and Rist Prizes, to F. Montariol and J.-P. Moreau. A special feature of the meeting will be a series of papers on non-destructive methods for the study and control of metals. Further information can be obtained from the Société Française de Métallurgie, 25 rue de Clichy, Paris 9e.

"Prophylaxis of Trypanosome Infections in Cattle"

Messrs. T. I. Watkins and G. Woolfe state that, in their communication under this title published in *Nature* of August 18, p. 368, they gave an incorrect structure for compound II. The correct structure is



II

Announcements

Mr. R. E. Glover, principal and dean of the Royal Veterinary College, has been appointed a member of the Agricultural Research Council in succession to Prof. G. R. Cameron, who has resigned; Prof. S. J. Watson has been appointed for a further term as a member of the Council and will continue as deputy chairman.

The fifth annual convention of the Scientific Instrument Manufacturers' Association will be held in Eastbourne during October 11–14, under the general theme of "Production 1957". There will be four panels on the following topics: general, optical and mechanical production; electrical and electronic production; research and development; and marketing. The guest speaker on the opening day will be Mr. Stanley J. Harley, of the Coventry Gauge and Tool Co., Ltd. Further information can be obtained from the Association at 20 Queen Anne Street, London, W.1.

A conference on "Gas Turbine Development", arranged by the Department of Engineering of the North Herts Technical College, Broadway, Letchworth, will be held in the College during October 20–21. There will be four papers, covering the development of the gas turbine in the following respective fields: industry; motor vehicles; ships; and aircraft. Further information can be obtained from the North Herts Technical College.

SCIENTIFIC CINEMATOGRAPHY IN GREAT BRITAIN

THE second Research Film Programme of the British Association, held at Sheffield on September 1, was opened by S. Bowler, vice-president of the Royal Photographic Society, by strongly supporting the idea of a central institute after the style of the German Institut für den wissenschaftlichen Film in Gottingen in order to raise the general standard of British research films. He was seconded by Dr. A. R. Michaelis, who had again organized the meeting on behalf of the Scientific and Technical Group of the Royal Photographic Society. Dr. V. G. W. Harrison was in the chair during the meeting, which was well attended by an audience numbering about 350 in the morning and more than 200 in the afternoon.

Outstanding among the work presented to the meeting were the two research films made by the strong team at the Chester Beatty Research Institute and University College, London. On behalf of the team, composed of P. C. T. Jones, K. Moreman (the cinematographer), D. M. Easty, M. Abercrombie and J. Santler, Dr. E. J. Ambrose introduced their film on "Interference Microscopy of Living Cells in Tissue Culture No. 2", in which epithelial cells were compared with certain carcinoma cells which develop from epithelium; interference cinemicrography in time-lapse frequency was employed throughout. This allowed not only a very clear appreciation of cytological phenomena but also often presented scientific material of great æsthetic beauty. He showed that, irrespective of their source of origin, epithelial cells formed very strong surface adhesions with each other, as distinct from carcinoma cells which moved quite independently, thus demonstrating a marked surface difference between these two types of cells.

Certain physico-chemical tests were carried out to substantiate this difference, and the negative electrical charge on the cell was measured in the presence and absence of various positive ions. The variations in the rate of movement of protein through the cell membrane in the presence of antiserum was also determined, and these changes were clearly seen in the film as rapid colour transformations in the cytoplasm of the compressed cells. The second research film from the Chester Beatty Research Institute was presented by R. J. Goldacre; it was entitled "New Aspects of Amœboid Movement". It was also recorded at time-lapse frequency, using partly phase-contrast and partly interference cinemicrography. Mechanical interference with the regulating mechanism of the polarity-conditioned locomotion of amœbæ led to the discovery of three new kinds of movement which were shown in the research film: first, rapid cytoplasmic oscillations with a frequency of 1–2 cycles per second and amplitude of 4–20 microns; secondly, cell rotation with suppression of noticeable cytoplasmic streaming and of locomotion; and thirdly, the transmission of contraction from one end of the cell to the other. In addition, interference cinemicrography was employed to investigate ingestion of phagocytosed prey by food vacuoles.

Bacterial swarming was the subject of a further interesting biological research film, presented by Drs. P. N. Cardew and H. Hughes, of the Wright-Fleming Institute and the Medical School, St. Mary's Hospital, London. It was called "The Swarming of *Proteus vulgaris*", and again time-lapse cinemicrography was employed. The growth of a single cell into a colony was followed, both on the plate and microscopically; the movements of abnormal long forms and details of swarming were clearly demonstrated. Further sequences dealt with the mutual interference of incompatible strains due to the production of primary toxic products and due to a second toxic influence, the accumulation of peroxide. That time-lapse cinemicrography is not confined to biological research topics was shown in the research film sent to the meeting by J. Newkirk, of the General Electric Company, Schenectady; it dealt with the growth, evaporation and phase-transformation of mercuric iodide crystals. The excellent use of colour in this film allowed an exceptionally clear understanding of the phenomena under investigation.

The interesting cinematographic technique of time-sampling was demonstrated in two films. The first, by J. Robertson, of the Tavistock Clinic, showed the behaviour of a two-year-old girl in hospital, when deprived of maternal care. At standard times during the day for regular intervals over 40-minute periods, the patient was filmed in order to obtain an objective record of her behaviour. Extracts from this scientific film, introduced by its author, showed clearly the marked difference in the child's behaviour when left to itself—fretting and depressed—and when playing with its mother during her visits—happy and contented. Next, Dr. P. Sainsbury, of the Westminster Hospital, presented his research film, "A Method of Measuring Spontaneous Movements by Time-Sampling Motion Pictures". He employed it as a quantitative technique for counting the gestural movements of his patients before and after leucotomy and of other patients with nervous tics; these movements are of a kind which cannot be counted individually. A signal-lamp was mounted out of view of the patient to flash at 5 or 2½ sec. intervals. Those intervals were counted as positive during which the specified movements occurred; when these movements were absent, the interval was scored as negative. Extracts from his research records were shown, demonstrating a decrease of gestural movements nine months after leucotomy. Further sequences dealt with the frequency of nervous tics of a number of patients during a variety of situations.

Colour schlieren cinematography at standard camera frequency was employed in the excellent film, "High-Speed Flow Around a Symmetrical Aerofoil", recently recorded by S. Beadle, of the Shell Film Unit at the Aerodynamics Division of the National Physical Laboratory, and introduced by A. Chinneck. Both at sub- and at super-sonic velocities, the movements of shock waves and the separation of the boundary layers were beautifully demonstrated, particularly when the air flow was increased from sub- to super-sonic velocities. The effect of changes of the angle of incidence of the aerofoil was also filmed. Cinematography at normal camera frequency has proved in the past of great value to record an experiment, which is unique, or difficult to repeat. A recent example of such use was the film "The Release of Cosmic Ray Balloons", made and introduced by J. H. Davies, of the H. H. Wills Physical Laboratory, University of Bristol. Balloon launchings extending over several years in Great Britain and abroad were filmed, and by careful analysis of these records it was possible to improve the technique considerably. The initial acceleration of the rising balloon could be reduced considerably by the use of a winch instead of employing many open-ended sandbags. Similarly, an undesirable mushrooming effect, leading to very high stresses in the envelope, could be eliminated by using a cord of undrawn nylon which stretched to several times its original length and thus allowed a gentle lifting of the heavy load.

High-speed cinematography was employed in three research films presented to the meeting. Wing Commander F. Latham, of the R.A.F. Institute of Aviation Medicine, Farnborough, began with unassisted escape from aircraft, showing the limitation of whole-body movements under sustained acceleration by comparing dummy and live-body trajectories on meeting high-speed slip streams at the commencement of free fall from aircraft exits. Camera frequencies up to 200 ft./sec. were used. The second stage, namely, of assisted escape from aircraft in the form of seat ejection, was similarly filmed and allowed a detailed physiological investigation of the tolerance of the human body to vertical impact acceleration and high-speed wind blasts. "Experiments of Sideways Launching" of ships was the next film to employ high-speed cinematography. It was extremely well recorded by C. A. Guthrie, of the Central Photographic Section of the National Physical Laboratory, often under most trying conditions. Scientific direction of this work was the responsibility of D. J. Doust, and the film was introduced by R. Silverleaf, both of the Ship Division of the National Physical Laboratory. The main problems concerned the possibility of capsizing due to insufficient stability, structural damage, and hull pressure due to impact. Full-scale launchings were filmed, sometimes from several different camera positions at the same time, and similarly model experiments with 1/18 scale models were recorded. From such experiments and these films, the performance of a variety of hull forms at launching can now be predicted and dangerous conditions of stability, way-end velocity and static drop can be avoided.

The only industrial research film presented at the meeting also employed high-speed cinematography, at a camera frequency of 1,000 ft./sec. It was made in colour and introduced by J. Underwood, of the Guest, Keen and Nettlefolds Group Research Laboratory. It dealt with "Flame Movement in an Open Hearth Furnace during Tapping" and was taken to investigate the causes of local overheating; from the resulting records it was possible to direct the research into profitable channels. During tapping the furnace is tilted, and from the research films made during this process, it became clear that the flame was not homogeneous, that patches of unburnt oil remained, and that the existence of turbulent edges showed undesirable changes of the aerodynamic conditions.

A number of comments may be submitted in this report. Out of the eleven presented, only one research film would find undisputed international acclaim—that introduced by Dr. Ambrose. Apparently only one research worker, Dr. Sainsbury, has used scientific cinematography in a metrical manner and has derived quantitative data from his research film; the majority of those presented could have been submitted to frame-analysis and would have yielded a mass of scientific information, completely lost by mere projection and visual inspection of the film. In nearly all cases a professional photographer or cinematographer was employed in the production of each film; yet much could be said in detailed criticism. These comments are strong support for the creation of a central institute from which advice, comment and specialized equipment could be obtained.

However, the general picture is encouraging and in the years to come may lead to an improved position. There can be little doubt that the aims of the organizers of this meeting were fulfilled by presenting a selection of the best research films available to an audience of scientists at the British Association. A third meeting is planned for September 7, 1957, at Dublin, and the hope can only be reiterated in this article that all those who have made new research films in the meantime will present their results; the films should be submitted to either the Scientific and Technical Group of the Royal Photographic Society or to the Scientific Film Committee of the British Association. A. R. MICHAELIS

CLIMATOLOGY IN THE SERVICE OF MAN

AT the Sheffield meeting of the British Association, Section E (Geography), under the presidency of Prof. A. Austin Miller, of the University of Reading, devoted a day to a series of contributions on "Climatology in the Service of Man", which might well be regarded as a very appropriate development following the presidential address (summarized in *Nature*, September 1 p. 474).

Prof. G. Manley opened by directing attention to the growing economic significance to Britain of the fact that we now import about 4 per cent of our fuel as coal or its equivalent. This is about equal to the difference in the requirement of fuel for heating purposes imposed by a severe season as compared with a mild one—the season comprising the months September–May. Variations in demand show an approximately linear relationship with the accumulated deficit of mean monthly temperature below a value which he took as 57° at sea-level. Official statistics of annual means back to 1866 have already been used in studies of variations in fuel demand; but for England and Wales monthly means are only available from 1901. Prof. Manley stated that his purpose was to extend our knowledge of the vicissitudes; he showed that a table of monthly means (*Quart. J. Roy. Met. Soc.*, 1953) giving representative values for the past 250 years now provides a reasonable index of the probable fluctuations of the heating requirement for the greater part of Britain. He directed attention to the occurrence in late Victorian times of the combination of a severe winter with a protracted cold spring, which if repeated would set up demands in excess of any seasons so far experienced this century, in which 1916–17 and 1950–51 gave the highest values. The highly irregular incidence of severe seasons gives as yet little reason for supposing that a protracted cold season such as occurred in the

1880's may not occur at any time. The need for further climatological research assumes greater urgency in view of our precarious fuel position.

Mr. M. Parry, of the University of Reading, followed with an appropriate reminder of the factors governing heat losses from a house. His remarks were based on studies made by the Building Research Station. Using the standard technique of degree-days, he then presented useful data from Reading, Bath and Nottingham to show the differences in fuel requirement likely to arise between houses of similar type, within and without the built-up area. Making further allowances for the wind factor, local variations of the order of 25–30 per cent in the annual fuel bill can be expected. Urban studies were rewarding.

Dr. Alice Garnett directed the attention of the audience to a variety of published studies in regard to atmospheric pollution, and went on to demonstrate the unpleasant—indeed disturbing and potentially lethal—accumulations which might be set up in certain parts of the Sheffield area, where a number of gauges have been established. Here she made effective use of maps indicating the association with local relief. She drew emphatic conclusions regarding the need for very close study of the problems which might arise from the siting of new 'industrial zones' in an area with such well-marked relief and a day-and-night outpouring of smoke.

Miss E. M. Frisby, who is working with a well-known commercial advisory and consultant organization in the United States, summarized the way in which climatological information can be presented for the use of various clients engaged, for example, in building construction in remote country, or in the processing of food crops. The comment was made that in Britain such provision of information is a public service.

The afternoon papers were primarily concerned with evaporation. Mr. G. Melvin Howe (Aberystwyth) demonstrated maps of seasonal water surplus and deficit, based on the Thornthwaite formulæ, for England and Wales. Clarity in cartographical representation is a valuable service which the geographer can and does render; a comment, however, might be that the representative character of the fundamental statistics used might be questioned in view of the local characteristics of stations to which Mr. Parry had earlier directed attention. Mr. S. Gregory (Liverpool) re-emphasized the need for water storage and conservation. In reminding the audience that since H. R. Mill geographers had taken little interest in rainfall, he summarized the type of work already done and stressed the need for further cartographical studies, especially in the north of England, where industrial demand for water is rising much more rapidly than was forecast.

Prof. B. J. Garnier, of Ibadan, brought in a welcome contribution from overseas. Irregular incidence of the short bursts of intense rainfall in Nigeria, coupled with very high evaporation, seldom much less than 4 mm. daily, explain why a slight deficiency is quickly felt. He showed how in relatively well-watered country irrigation may nevertheless be very valuable, especially as the increase in the population will soon necessitate more intensive production of food.

Mr. J. L. N. Sibbons (Sheffield), at the end of the session, taxed the non-mathematical part of the audience; he gave a carefully reasoned demonstration of the difficulty of determining the potential loss of moisture under specified climatic conditions. He showed that the assessment of evaporation-losses by the Thornthwaite method breaks down in certain unusual climates. From another point of view he showed that Penman's approach is also open to some criticism; and, taking account of Sir Graham Sutton's work, he proposed equations which would give better estimates. This was a bold and well-reasoned paper in an exacting field, and it is to be hoped that Mr. Sibbons's ideas will find outlet in print; at least one expert from the Meteorological Office was observed to be engaged in animated comment on the equations on the board.

The papers were varied, and served at least one useful purpose, in that they showed the value, as a shorthand summary of results and as a stimulus to discussion, of well-drawn maps and diagrams, although at times the observational basis may be open to question. Many in the audience were perforce little acquainted with the numerous specialized studies now forthcoming from various sources and research groups. The critically minded geographer can render a useful service in assembling and filtering such material. The geographical approach, moreover, can be illuminating, in that the results of scientific investigations can be related to a particular area and tested by the members of the audience against their own direct field-experience and observation elsewhere.

INTERNATIONAL UNION OF FOREST RESEARCH ORGANIZATIONS

CONGRESS IN OXFORD

The Twelfth Congress of the International Union of Forest Research Organizations was held in Oxford during July 7–14 under the presidency of Prof. Aldo Pavari, of Florence. At this, the first occasion on which the Union had held a Congress in Britain, about 250 delegates attended, from forty-two different countries. The Union, which was founded in 1890, is an association of forest research institutes, including universities, industrial research stations and State institutes, and its main purpose is to advance research into forestry problems. Originally a Union of Central European stations, it has steadily expanded until it now has members in all parts of the world; it is still attracting new recruits, and among recent accessions are the Academy of Sciences of the U.S.S.R. and the research stations of the Forest Service of the United States.

Most of the meetings of the Congress were held in the Imperial Forestry Institute; but the opening and closing ceremonies took place in Regent's Park College, Oxford. The Congress was formally opened by the Minister of Agriculture, Fisheries and Food, Mr. D. Heathcoat Amory, who spoke about forest policy in Great Britain and the place which research has taken in recent developments. He mentioned that much of the earlier effort was devoted to establishing crops of trees on land which had carried no tree growth for centuries; after about thirty years of effort, many of the problems of establishment have been solved, and British research workers are now turning their attention to the problems of managing forests. Work study and mechanization are being dealt with, and much interest is being taken in the effect of trees on the soil. Mr. Amory also referred to research into the qualities and properties of timber, a subject most essential to foresters, who must never lose sight of market requirements.

The work of the Congress was carried out in Sections, of which there are nine, each dealing with a different subject, and discussions continued during the week, except for a break on July 12 when delegates visited Rothamsted Experimental Station, the Forest Products Research Laboratory at Princes Risborough and the Forestry Commission's Research Station at Alice Holt, near Farnham.

The section leaders, who continue in office between Congresses, are responsible for keeping in touch with all the research workers in their respective fields of action, for circulating information of interest to members of their Section and for initiating action when this is necessary. The Section on Forest Influences, under Sir Harry Champion, of Oxford, dealt with two main subjects: the effects of shelter belts on agricultural and horticultural crops and on livestock; and the effect of forest growth on water supplies. On shelter, it was recommended that there should be an expansion of research into the influence of different types of shelter-belt on crop yields, using modern statistical methods wherever possible; in this work, closer contact with those engaged in plant and animal husbandry is of great importance. More information is needed on the effect of tree roots on agricultural crops under various conditions, on the shelter effect of scattered trees and groups of trees on pasturage and on the influence of systems of shelter belts on regional climates. The effect of forest cover on water supply is a difficult subject to treat experimentally, and the Section recommended the setting-up of a working party to study research methods and procedures. Attention was directed to the lack of comparative watershed data from the more tropical dry or seasonally dry regions, and the need was stressed for a study of the theoretical foundations and the practical application of the concept of evapo-transpiration. The Section also asked member institutes to pay more attention to research on forest influences in the humid tropics.

Under Prof. A. de Philippis, of Florence, the Section on Site Factors dealt with plant communities and their importance to practical forestry. With the help of phytosociological methods, there are many problems which can be solved quickly as, for example, the improvement of indigenous stands, the acceleration of forest successions, the conversion of forests to more favourable sylvicultural types, and the choice of species for forest plantations. The Section recommended that rules of international application should be drawn up for uniform methods of forest mapping and for uniform procedure in classifying and naming forest communities.

Dr. C. Syrach Larsen, of Denmark, and the Section on Forest Plants, spent some time in a discussion on teak, as a result of which further work on the flowering of this tree was called for as well as provenance trials. There was some discussion on the selection of stands and single trees for seed production and tree breeding, subjects in which there is at present a wide interest. Some countries, among them Great Britain, have started to compile registers of individual trees and of crops of trees which are suitable sources of seed, and the Section recommended that countries which had not started on this work should begin forthwith. Subjects to which special attention should be paid before the next Congress are methods for the mass production of seed, the place of the Mexican pines in sylviculture and provenance types of Douglas fir.

The Section on Sylviculture, under Prof. H. Leibundgut, of Zurich, dealt with methods of classifying trees and spent some time in discussing how to assess the effect of various methods of tending forest crops on growth and quality. The wide field of practical sylviculture was also dealt with.

Dr. H. van Vloten, of Wageningen, leader of the Section on Forest Protection, dealt with research into population dynamics and discussed virus diseases of insects of importance in forestry. The possibility was also examined of securing international co-operation in making trial plantations of important tree species in several continents in order to study resistance to diseases and pests.

The Section on the Study of Growth, under Prof. Y. Ilvessalo, of Helsinki, considered the methods of studying yield and growth in forest crops, the variations in yield arising from climatic factors and the determination of the amount of timber which may be cut. It was agreed to form a working-group to examine the possibility of standardizing methods of measurement and to consider how best to circulate information on instruments used in forest mensuration.

Prof. J. Speer, of Munich, presided over the Section on Forest Economics, which dealt mainly with costs in forest operations. In this field, terminology is of importance if the performance in one country is to be compared with that in another, and the Section decided to study this subject with the view of clearing up the obscurities which exist at present. It was also agreed to promote further studies on interest, which plays an important part in the long-term calculations common in forestry, and on the productivity of forest labour. This last item touches closely on the work of the Section on Operational Efficiency, which met under its leader, Prof. U. Sundberg, of Stockholm. In this Section, the two principal subjects which were discussed were medical and physiological problems in forest work, on which much research has recently been done in Sweden, and transport in the forest in relation to the efficiency of operations.

The Section, under J. Campredon, of Paris, which is concerned with the properties and uses of timber discussed the influence of site and of provenance on the quality of the timber, and recommended further research in this field in conjunction with ecologists, geneticists and physiologists. It was also decided that fresh studies should be made of methods of sampling for the qualitative study of timber.

Immediately before the Congress, the Committee on Bibliography, a body in which the Union and the United Nations Food and Agriculture Organization are jointly concerned, met under the chairmanship of Prof. E. Saari, of Helsinki. This Committee has encouraged the use of the Oxford Decimal System of Classification for Forestry and is arranging for its translation into various languages. It is also participating in the preparation of a multilingual forest terminology, and is promoting co-operation between a large number of national and regional centres of forest bibliography; the three international centres are in Oxford, Reinbek and Washington, D.C.

Towards the end of the Congress, the senior delegate from Poland, Prof. M. Kreutzinger, of Warsaw, announced that the Polish Government had decided to offer Great Britain a breeding pair of

European bison for scientific study. The bison in Poland suffered much during the two World Wars, and it is reassuring to learn that stocks of this fine forest animal are slowly building up again. Prof. Kreutzinger stated that at present there are eighty-four bison in Poland reasonably represented by sex and by age and that the annual crop of calves is now about fourteen.

The Union elected Mr. James Macdonald, director of research and education of the Forestry Commission, Great Britain, to be president in succession to Prof. Pavari, whose term of office expires at the end of this year. Dr. van Vloten was elected vice-president. The Permanent Committee of the Union was enlarged, and now consists of the following members: Dean C. F. Korstian (Duke University, North Carolina); A. Oudin (Nancy); Prof. M. Kreutzinger (Warsaw); Dr. K. L. Aggarwal (Dehra Dun); Dr. V. L. Harper (Washington, D.C.); Prof. M. Näslund (Stockholm); Prof. A. Uzcategui (Venezuela); Prof. M. Ohmasa (Tokyo); Prof. A. Horky (Vienna); Prof. T. Bunusevac (Belgrade); and a representative, yet to be appointed, of the Institut National pour l'Étude Agronomique du Congo Belge. The Union accepted an invitation from the Government of Austria to hold its next Congress in Vienna.

After the Congress at Oxford, about a hundred and forty of the delegates took part in study tours, which lasted for a week and of which seven were conducted in different parts of Great Britain. During these tours an attempt was made to show the visitors as much as possible of the research in forestry and closely allied subjects which is proceeding at the present time in Great Britain, to inform them of the major problems still awaiting solution and to give them an impression of the variety of conditions in the woodlands and forests in the country.

J. MACDONALD

SELECTION OF MANAGERS

AT the annual general meeting of Unilever, Ltd., the whole of Lord Heyworth's speech was devoted to the way this organization is managed. The Unilever organization is an Anglo-Dutch partnership operating several hundred companies in more than forty different countries; a manager is one to whom is entrusted, at whatever level, the supervision or direction of others. There are altogether some 22,600 managers in Unilever, out of a total labour force of about 270,000; managers form 8 per cent of the total. Inside the general pattern the proportion of managers to the whole varies from one part of the business to another, and from one country to another.

At one end of the scale are the plantations in Nigeria and the Cameroons, where both the country and the operations are still comparatively simple. Here the managers form only about 3 per cent of the whole. In Indonesia, on the other hand, where there is a business producing both detergents and edible fats, the proportion of managers has risen to 6 per cent. In the United Kingdom, with operations in detergents, edible fats and other foods, oil-milling and toilet preparations, the proportion of managers to the total labour force reaches 11 per cent; in Holland with the same range of operations, it is about the same. In the highly sophisticated conditions of the United States, where Unilever interests embrace detergents, toilet preparations, foods and oils and fats, the managers form 15 per cent of the total of the employees. The pattern that emerges is that the higher the degree of mechanization and the more sophisticated the environment, the higher will be the ratio of managers required.

The managers fall into three main categories. At the base of the pyramid there are the junior managers, numbering about 16,400. Of these there are some 5,000 in Great Britain and 800 in Holland. This category includes the foremen and supervisors. Next comes the large class of middle and senior managers, totalling about 6,000. At the apex is the top management, the two or three hundred people who take on themselves the decisions which make or mar the success of the business as a whole. The only test applied to determine a man's suitability to enter the managerial ranks is that of merit. No particular social or educational background is demanded. An increasing proportion of prospective managers have had a university education; but Lord Heyworth forecasts that in future, as to-day, many Unilever managers will be men who came in at one of the lowest levels, who "came up the hard way" and whose qualities of leadership were developed after they had joined the business.

Selection is a matter in which decentralization is essential. In general, it is left to the individual companies and local managements throughout the world to do their own selection, whether from within their existing ranks or by recruitment from outside. They can, and do, draw upon the common fund of knowledge and experience which has been accumulated by the personnel divisions at the Company's headquarters; as a result, the technique of selection everywhere conforms more or less to a common pattern.

One basic principle is that the qualities of the potential recruit are assessed not merely by individual interview but also by seeing him perform as one of a group; he can show whether he possesses such obviously desirable qualities as intelligence, common sense, organizing ability, and the ability to get on with others. Some men are picked primarily for their specialist knowledge, and special attention is paid to developing their general management ability in the business. The man must have the germ of leadership within him, however; it seems to be more difficult at the stage of initial selection to detect this germ in the technical man than in the non-scientist. For the man reading science at the university to-day the curriculum is so specialized, and so much time has to be spent in the laboratory and lecture room that special attention may have to be paid to help him to broaden his outlook. From Unilever experience it is known that technological skill and management ability are far from incompatible.

The most important training is that which is done individually and on the job, and this must be flexible and selective. There is no general scheme of training into which everyone will fit. Training should be tailored to measure and not ready-made. Immediately, or after a short settling-in period, a man is given a job, and in that job he starts to learn the art of being a manager. This training of the men under them is a vital part of the work of all managers, and the man who neglects it or regards it as a waste of time is unlikely himself to reach the heights.

To this basic training on the job, courses provide a most valuable reinforcement, and in these post-war years this form of training has been greatly extended. Unilever courses are of two main kinds.

There is the general course, primarily designed to give a man the broad picture of industry and its economic background and to tell him something of Unilever as a whole.

The second category, the more specialized courses, are mainly devoted to teaching a particular technique such as production study, accountancy, advertising, or some technical process.

For more senior managers the opportunity may arise of going to an outside institution such as the Administrative Staff College at Henley, Nijmegen in Holland, and the advanced courses available at such places as the Harvard School of Business Administration in the United States. People are sent to all these places, sometimes to that in their own country, sometimes abroad. Then there are the courses run by universities, summer schools of business and the like, lasting three or four weeks. Industry should make a contribution, not only by ensuring that the quality of those whom it sends as students is high, but also by seconding first-class men to assist on the instructional side. If the universities are going to develop the teaching of business administration, Lord Heyworth would favour the experiment of seconding the university teacher to industry for a year or two, and so giving him an inside view of how industry works before he returns to the university to teach.

There are certain obvious advantages in possessing a corps of managers trained up in the business, professionals who at the start of their working life have made industry in general and Unilever in particular their chosen career. But there are always the dangers of inbreeding—the tendency to rest content with things as they are and to play safe, to follow precedent, to play down initiative and originality and to keep one's nose so closely to the Unilever grindstone as to let change and development in the outside world pass by unnoticed.

It may be that more interchange from one business to another at senior levels would be no bad thing. Pension rights are sometimes a difficulty, and these should not be used for fettering a man to his present job with chains of gold. In the United States, it has become the accepted pattern for a man to move upwards by switching from one business to another without suffering any stigma of disloyalty or careerism.

COURSES IN HIGHER TECHNOLOGY

THE White Paper on Technical Education which was presented to Parliament in February indicated that the annual output from advanced courses at technical colleges should be increased as soon as possible from 9,500 to 15,000 and that, as industrial techniques develop, refresher courses would be essential to provide opportunities to enable industrial personnel to keep up to date. The London and Home Counties Regional Advisory Council for Higher Technological Education hopes that, by stimulating colleges to provide special courses in branches of engineering, science, chemistry, management, production and commerce, it is making a contribution to the country's need. These are described in a recent bulletin*. The purpose of the bulletin is to give publicity to special advanced courses held in London and the surrounding counties which do not regularly appear in college calendars or prospectuses as part of a grouped course or as subjects offered for endorsement on Higher National Certificates. They are as a rule part-time (usually evening) courses; but full-time courses which are specially arranged and are not of longer than three months' duration are also included. Short courses organized by the University of London are also described in the Bulletin.

Since the issue of the first Bulletin in August 1950 many thousands of employees have attended the courses advertised. The Council forms a link between education and industry, and requests from industry for further courses on topics of interest will be gratefully received and carefully considered.

Among the courses offered are the chemistry and technology of cosmetics, analysis of power units by the use of non-dimensional plotting, microwave techniques and measurements, pulse techniques, restrictive practices and monopolies, rate processes in solids, aerofoil theory and supersonic dynamics, and electronics for biologists.

EARTHQUAKES IN KERN COUNTY, CALIFORNIA, DURING 1952

IT is probable that no earthquake in history has been studied in the field by so many people as was the Arvintehachapi (magnitude 7·7) earthquake of July 21, 1952. This earthquake, one of the greatest three in Californian history, occasioned a series of aftershocks in the southern San Joaquin Valley, 220 of which, up to the end of June 1955, attained magnitude 4 or greater (Bull. 171 of the Division of Mines, Department of Natural Resources, State of California; by 36 authors and 16 Co-operating Agencies; pp. 283; November 1955). The focus of the shock was at lat. 35° 00′ ± ¾′ N., long. 119° 01′ ± 1¼′ W., depth about 15 km., and it occurred at 11h. 52m. 14·2s. ± 0·13s. The epicentre was near the eastern end of Wheeler Ridge on the Whitewolf steep reverse fault. This thrust has a strike N. 50° E. and is rather more than thirty-two miles in horizontal extent. B. Gutenberg has calculated that at the focus the fault plane has a dip of about 60°–66° towards E. 50° S. and that the slip along the fault at this depth when the earthquake happened was roughly up towards north in the upper (south-eastern) block relative to the lower (north-western) block. The vertical component of the slip was about 1·4 times that of the horizontal, the horizontal component corresponding to a relative movement north-east in the upper block and south-west in the lower block.

Surface measurements were made by triangulation by officers of the United States Coast Guard Service. Horizontal movements were small, and the Bear Mountain block moved north-east about two feet. Some fifteen miles south of Bakersfield the differences in elevation were 3–4 ft., the area to the south being uplifted and the area to the north lowered. The sharpest break was six miles south of Arvin, at Comanche Point. According to J. P. Buwalda and Pierre St. Amand, the earthquake did not develop a simple clean-cut trace along the fault, like the strike-slip ruptures on the San Andreas fault near San Francisco in 1906 and in the Imperial Valley in 1940, or like the dip-slip scarps on the Sierra Nevada fault along the Alabama Hills in Owens Valley in 1872, or like the fault along the east side of Pleasant Valley, south of Winnemucca, Nevada, in 1915. Instead, a complex pattern of ruptures in a zone along the fault, a half-mile or more in width, was formed. The faults were sometimes made apparent by mole-track pressure ridges. According to Hugo Benioff the volume of strained rock was $7 \cdot 3 \times 10^{19}$ cm.^{3}, the average strain prior to the shock $8 \cdot 7 \times 10^{-5}$, average stress 26 kgm. cm.$^{-2}$, purely elastic strain-energy density $6 \cdot 6 \times 10^2$ ergs cm.$^{-3}$ and creep-strain energy about 5×10^2 ergs cm.$^{-3}$.

* Bulletin of Special Courses in Higher Technology, including Management Studies and Commerce, 1956–7. Part 1: Autumn Term 1956. Pp. 82. (London: London and Home Counties Regional Advisory Council for Higher Technological Education, 1956.) 1s. 6d.

Frank Neumann and W. K. Cloud measured the maximum ground acceleration recorded on an accelerograph of the U.S. Coast Guard Survey at Taft, thirty-five miles from the area of greatest intensity, as 0·22 *g* for a wave of period 0·22 sec. They believe that the maximum acceleration in the central area, where the intensity on the modified Mercalli Scale was 9, may have been between 0·35 and 0·5 *g*. For comparison, in the Imperial Valley earthquake of 1940, an acceleration of 0·34 *g* was registered at El Centro, four miles from the area of maximum intensity. A full account of structural damage and the lessons to be learned from it are given in the bulletin.

PROTEIN METABOLISM, RESPIRATION AND GROWTH

A SYNTHESIS OF RESULTS FROM THE USE OF ^{14}C-LABELLED SUBSTRATES AND TISSUE CULTURES

By Prof. F. C. STEWARD
Department of Botany, Cornell University, Ithaca, N.Y.

Dr. R. G. S. BIDWELL*
Department of Biology, Queen's University, Kingston, Ontario

AND

Prof. E. W. YEMM
Department of Botany, University of Bristol

THE proximate causes of growth and differentiation represent a great unsolved problem, while the mechanism of protein synthesis and the ability of units of the cell for self-duplication still defy explanation. To understand both normal and abnormal (cancerous) growth, the over-riding need is for greater knowledge of why cells grow by division and by enlargement. For the investigation of these broad problems, plant-tissue cultures are very suitable, and especially if cultures which are rapidly growing by random proliferation may be contrasted with similar cultures which merely remain in a state of rest, or relative inactivity. In the differences between the same tissue in these two states must be clues to many unsolved problems.

These conditions are well met by the use of small (3-mgm.) tissue explants from the secondary phloem of the carrot root, cut so far (1–2 mm.) from the cambium that cell division in the root has virtually ceased. Such tissue explants are exposed to a liquid nutrient medium under aseptic conditions which accurately reproduce their growth[1–4]. The more familiar nutrients, organic and inorganic, supplied in relative bulk, or at the level of requirement of the familiar vitamins, as in standard media for plant tissue cultures, permit only very slow growth by cell division or sluggish growth by cell expansion. However, when the nutrient media are supplemented by growth factors present in coconut milk (a fluid that typically nourishes an immature embryo), rapid growth by cell division ensues, leading to a proliferating mass of relatively small cells. Thus this tissue system may be placed, reversibly and at will, in the condition of comparative rest or of rapid cell division. Moreover, the induction of growth is evidently due to the stimulus of specific substances which supplement the nutrients in the basal medium. Therefore, the metabolic characteristics of growing and non-growing cells may be contrasted.

The extent of the coconut milk stimulus to cell division may be seen from the following. An initial carrot-tissue explant (about 3 mgm.) contains approximately 23–25 thousand cells. During the first three or four days of contact with the culture medium, even if this contains coconut milk, the explant tends to increase more by enlargement than by cell division; but, thereafter, the number of cells in the culture increases very rapidly, reaching approximately 200,000 in about seven days and approximately 340,000 in about twelve days. In this large number the cells so produced remain very much smaller than their counterparts in the original tissue and they are also very much smaller than the cells of similar tissue explants which remain in media unsupplemented by coconut milk and in which their rate of cell division is by comparison slow. (After twelve days in a normal basal tissue culture medium the number of cells per explant increases to about 31,000.)

The effects of the coconut milk are now attributable to certain specific substances. Some of these have been isolated from the coconut milk itself and obtained in the crystalline form, although they are not as yet fully identified (compounds *B*, *C* and *F* of Shantz and Steward[5,6]). Some, as for example compound *A* of Shantz and Steward[7], have been both isolated and identified (1,3-diphenylurea), and still others, obtained both from coconut milk and other sources such as the immature fruits of *Aesculus*, have been generally identified as belonging to a definite class of chemical substances, for example, the leucoanthocyanins[8]; and still other synthetic substances (benzthiazolyloxyacetic acid) have been found to be unexpectedly effective in stimulating cell division in this tissue system[8]. 6-Furfurylaminopurine (the substance 'kinetin' of Skoog, Miller *et al.*[9]) is apparently not a naturally occurring substance but is derived from nucleic acid by the action of heat, etc.; this substance causes cell division in carrot tissue in the presence of indoleacetic acid, but not nearly to the extent of coconut milk.

---

* Present address: Atlantic Regional Laboratory of the National Research Council of Canada, Halifax, Nova Scotia.

The present article is a résumé of work carried out on carrot-tissue explants placed, by the use of coconut milk, in the conditions of rapid growth and also, by withholding it, retained in the conditions of very slow growth. The general plan was to find the different ways in which the tissues use certain ^{14}C-labelled compounds, supplied exogenously as substrates for respiration and protein synthesis. However, quite unexpected conclusions could also be drawn, and these have a very direct bearing on the differences between fast-growing cells on one hand and the slow-growing cells on the other; they also bear upon the specific effects of the substances, natural or synthetic, that induce growth by cell division.

Experimental Design

The entire experiment was carried out on a uniform population of carrot-tissue explants from the same root. In a pre-period of seven days the explants were allowed to establish the two contrasted states desired, namely, the growing state in presence of coconut milk and the relatively non-growing state in its absence. At this point the exogenous treatments with the radioactive substrates were given, and their effects were followed over the ensuing five days, tissue samples being obtained at approximately daily intervals. In this way the effects of each substrate were determined and their time course observed. At each sampling period the following observations were made: (1) The fresh weight of the tissue explant. (2) The total amount and specific activity of the respired carbon dioxide evolved during the period. (3) The tissue was extracted with alcohol, and upon this extract subsequent chromatographic and radioautographic observations were made. (4) The alcohol-insoluble portion of the tissue was hydrolysed and the resultant extract was again subjected to subsequent chromatographic analysis. (5) The external solution was analysed to determine the change in the radioactivity which had occurred.

By the application of paper chromatographic methods combined with appropriate procedures of radioautography, the following determinations were made: (1) All the identifiable nitrogen compounds present in both the alcohol-soluble extract and the acid hydrolysate of the alcohol-insoluble material were determined quantitatively. This was done using a phenol/collidine–lutidine system. For each of these constituents, eluted from the paper, the total radioactivity was determined, and the specific activity was calculated. (2) A similar procedure on the same chromatogram was applied to the sugars, fructose being determined separately, glucose and sucrose combined as one sample.

Combining the data from the growth of the tissue cultures and the analytical data, one can calculate the *total amounts* of each constituent present in a tissue explant at a given time and thus determine the absolute changes which occurred with time as a consequence of the experimental treatments. The radioactive substrates supplied singly in trace amounts to the media of both growing and non-growing tissue were as follows: (1) ^{14}C-uniformly labelled glucose obtained biosynthetically from tobacco leaves by Dr. P. V. Vittorio, of Queen's University, Kingston. (2) Uniformly labelled ^{14}C-glutamine obtained biosynthetically from Swiss chard leaves by one of us (R. G. S. B.). (3) Uniformly labelled ^{14}C-γ-aminobutyric acid obtained from the glutamine by use of a suitable decarboxylase preparation, this conversion being carried out by one of us (E. W. Y.).

In the choice of these substrates the ideas were as follows. The use of ^{14}C-labelled sugar was expected to show the extent of the direct use being made of glucose in the processes of respiration leading to evolution of carbon dioxide and also the ease with which this sugar enters into other concomitant metabolic reactions, such as those of protein synthesis. Glutamine looms large in all modern ideas of plant nitrogen metabolism and it was regarded as a most likely point of departure for protein synthesis: by the use of ^{14}C-labelled compound it was expected that this could be traced. Since its discovery, γ-aminobutyric acid has been regarded as a possible decarboxylation product of glutamic acid[10]. The experiment offered the opportunity to test whether the γ-aminobutyric acid merely acted as an alternative source, by carboxylation, of glutamic acid, or indeed, whether the tissue could utilize this substrate at all.

Role of γ-Aminobutyric Acid in Relation to Glutamine

γ-Aminobutyric acid in higher plants has been thought to arise by decarboxylation from glutamic acid[10]. However, the radioautographs and the specific activity data, etc., show very clearly that when γ-aminobutyric acid is supplied to the tissue it passes readily to glutamic acid and glutamine and then into other nitrogenous substances. On the other hand, when ^{14}C-glutamine is supplied the conversion to γ-aminobutyric acid is slight and even negligible after 100 hr. One must therefore regard γ-aminobutyric acid, now known to be of very frequent occurrence free in plants, not merely as a waste or decarboxylation product of glutamic acid, but rather as a substance which is en route to glutamic acid and glutamine. Whatever the method of its use or synthesis, γ-aminobutyric acid is now to be regarded as an important metabolite capable of donating both carbon and nitrogen in the active metabolism of growing and non-growing plant cells[11].

For purposes of the comparisons required, the basis to which the analytical data were calculated was the individual tissue explant. Proceeding in this way the *total amount* of each metabolite present in a single culture was recorded, or calculated, so that the absolute changes of these substances with time could be determined. Owing to the rigorous control achieved under the experimental conditions it was possible to carry out all these various processes with gratifying accuracy.

Specific Activity of Tissue Metabolites and its Interpretation

When first recorded, the total radioactivity present in a given substance in the tissue was represented not merely in the units 'total counts per minute' but as the equivalent weight (μgm.) of carbon with the same activity as that of the source: the specific activity of the carbon in the compound therefore becomes the percentage of the carbon present in the compound which had the same activity as the source. Thus the specific activities of the compounds present in the tissue are always represented by percentages of the specific activity of the source supplied. However, it became evident that it was possible for a compound in the tissue to have a specific activity *greater* than the metabolite within the tissue from which it must have been derived. Re-evaluating this situation, we became impressed by the following facts.

Since the cell is a heterogeneous system, it is entirely possible for two immiscible metabolic pools to co-exist and to contain the same substrate, which may be subject to different reactions or to similar reactions proceeding at different rates. Thus, it may arise that a given compound may be subject in a given time to increase from one source and decrease from another; that is, there may be both entry and withdrawal from the total complement of this substance in the cell. Thus, carbon of high specific activity may be entering the substrate in question in one cellular phase, while carbon of low, or zero, activity is either entering or leaving that same substance in another phase. Since on analysis the two phases become mingled, the average specific activity of the compound in the cell as a whole may bear no direct relationship to its place in a metabolic sequence of events.

To clarify such situations, the additional information that is required is the *specific activity* of the carbon which is in transit *to and from the metabolite in question.* In order to obtain this, the following data were necessary: (1) the change in a given period in the total carbon contained in the metabolite in question; (2) the change in the same period in the activity contained in the metabolite in question.

From this, by dividing (2) by (1), the specific activity of the carbon *in transit* may be determined. Thus, throughout the investigation it was found necessary to record changes in the metabolites in the following way: (1) the change in the total carbon present in the metabolite (Δ total C); (2) the change in total activity, recorded by its equivalent of carbon ($\Delta \text{ C} \equiv$ activity); (3) the specific activity of the carbon appearing in, or disappearing from, the pool of the substance in question, recorded as a percentage of the specific activity of the carbon in question

$$\left(\frac{\Delta \text{ C} \equiv \text{activity}}{\Delta \text{ total carbon}} \times 100\right)$$

The utility of this form of analysis may be illustrated by some of the results obtained with reference to glutamine and glutamic acid; these are summarized in Table 1.

From Table 1, it is not surprising that the glutamic acid actually present in the tissue achieved during the period had nearly the same activity as the carbon source which was supplied. It is more surprising, however, that the glutamic acid derived from glutamine actually had higher specific activity than the glutamine contained in the tissue. This obviously means that there is a non-radioactive pool of glutamine in the tissue; but the other conclusion which follows is that the glutamic acid in the tissue must have been derived from the active pool of glutamine, not from the inactive pool. Thus the two pools of glutamine must have been separated in the cell. From the last column in Table 1, it is apparent that two-thirds of the carbon involved in the *change* in glutamine content of the tissue came from an active source and one-third from an inactive source, whereas the corresponding figure for glutamic acid is obviously anomalous. The carbon involved in the metabolic change of glutamic acid during the period apparently came from a source which had a specific activity more than twice that of the ultimate source of the activity in question. The anomaly referred to in connexion with glutamic acid is but one of several types of anomalous result that are encountered under this mode of procedure. Such anomalies are of the following kinds in which the metabolic change may seem to have been mediated by (1) carbon far richer in activity than its actual source, (2) carbon far less active than that actually supplied, (3) by carbon of an infinitely high activity, or (4) by carbon of an activity that appears to be arithmetically negative. Obvious explanations which cover these various type situations are:

Table 1. FREE GLUTAMIC ACID AND GLUTAMINE IN THE FAST-GROWING CARROT TISSUE SUPPLIED WITH ^{14}C-GLUTAMINE DURING PERIOD 1 (0 to 22 hr.)

Tissue metabolite	Specific activity of C*	Δ Total C†	$\Delta \text{ C} \equiv$ Act.‡	$\frac{\Delta \text{C} \equiv \text{Act.§}}{\Delta \text{ Total C}} \times 100$
Glutamine	66	261	175	67
Glutamic acid	99	19	44 3	233

* As per cent of specific activity of the carbon in the supplied glutamine.

† Change in μgm. of carbon in the metabolite present in 10 explants.

‡ Change in μgm. of carbon of the same activity as the source to account for the change in total activity in the metabolite.

§ The apparent specific activity, as a percentage of that of the source, of the carbon in transit to the metabolite.

(1) This refers to a situation in which there is concurrent disappearance of the inactive compound from one cellular phase while it is increasing in the radioactive form in another. This leads to the apparent use of carbon of a specific activity higher than the source.

(2) In this situation the specific activity appears to be less than that of the source: this could arise either by dilution of the active compound by the inactive metabolite, or else by the concurrent appearance of the inactive compound synthesized in one phase while it is increasing in the radioactive form in another.

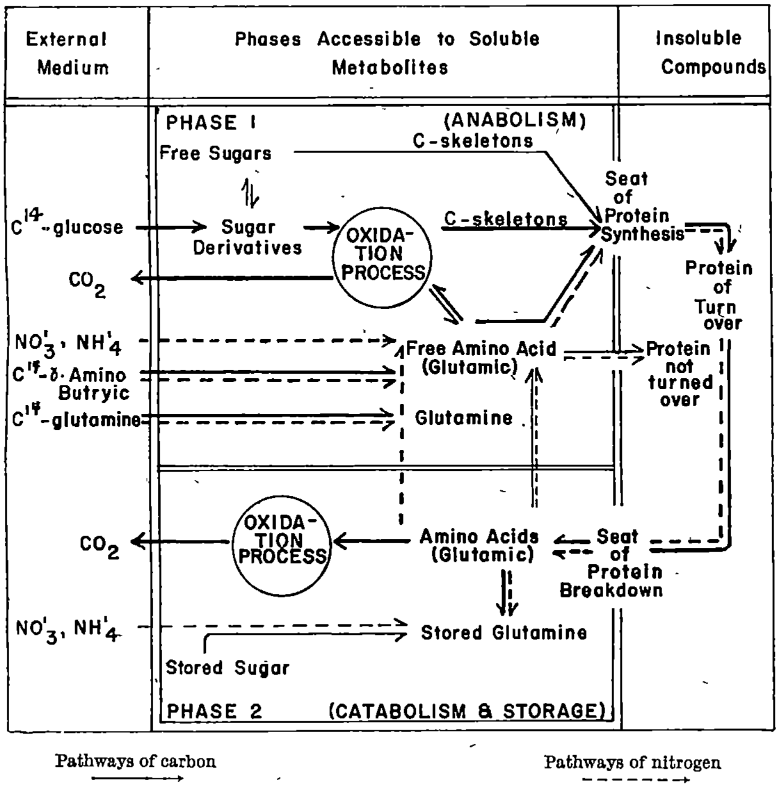
(3) Here the carbon involved in the reaction appears to have been of infinitely high activity: this must imply that there is no net change in the metabolite in the cell as a whole, although there has been synthesis of the radioactive compound in one phase with concurrent disappearance of its inactive form from another phase.

(4) This situation is one in which the carbon involved in the metabolic reaction during the period appears to have negative activity. This anomaly results when there is a decrease in the metabolite in the cell as a whole, during a period in which some radioactive synthesis occurred, or again by a greater increase of the inactive compound in the cell than there is decrease of the radioactive compound in the cell.

While there is nothing intrinsically new in these ideas, the merit of this method of formulation is that the unusual and anomalous events become immediately obvious so that they can be subjected to further analysis and interpretation. In one way or another, all the type situations indicated above were encountered in the experiments in question, and this compels the interpretation of the data in ways which take account of the separation of the metabolites in different phases in the cell and the existence, in these phases, of concurrent and different reactions.

Interpretation of the Respiring, Synthesizing Cell in Terms of Separate Phases or Compartments

The entire body of data may be comprehended in terms of the scheme which is illustrated in Fig. 1.



Pathways emphasized by the experimental treatments are indicated by heavy lines

Fig. 1. Diagram to illustrate the main metabolic pathways in cultured carrot tissue explants

Comment on this scheme will be in two parts: first, the novel features will be stressed; and second, sufficient data will be given to indicate how it rests on experimental evidence.

(1) An important, though certainly not new, feature of the scheme is the idea that protein participates in respiration and contributes to the carbon dioxide. This idea, probably first stressed by Gregory and Sen[12], has also been used for explaining certain characteristics of tissue slices[13,14].

(2) The scheme is based upon the recognition that the cellular organization provides for different phases in which compounds may exist without equilibration and may participate in distinct metabolic reactions. In phase 1 the emphasis is on anabolism and protein synthesis; in phase 2 the emphasis is on catabolism, protein breakdown and storage. In both these phases oxidation processes are conceived to occur with the ultimate formation of carbon dioxide. The oxidation processes in both phases may well involve the same enzymatic systems, the distinctive feature of phases 1 and 2 being rather the accessibility of the enzymes to the products of protein breakdown on one hand (No. 2) or to the seat of protein synthesis on the other (No. 1). At this stage no attempt is made to identify the phases with known morphological features, or even to recognize a degree of geographical separation beyond that which is imposed by selective accessibility of particular substrates to the enzymes in question. In other words, there are areas within the cell which are specialized for these particular metabolic functions.

(3) The scheme recognizes that amino-acids and amides, when they are supplied exogenously, or arise from protein breakdown, are separated in the cell, and active protein synthesis is thus relatively independent of the pool of free amino-acids and amides. In these circumstances, protein synthesis is not visualized as the mere condensation of the *free* amino-acids; but carbon skeletons, largely derived from sugar, condense with nitrogenous groups (for example, from glutamine and glutamic acid), and these are embodied in the protein molecule at the seat of synthesis. If amino-acids are intermediates in this synthesis, then these molecules may not occur free and they do not permeate the cell as a whole.

(4) The scheme also recognizes that continuous turnover of proteins takes place, but that different moieties of the cell proteins may participate therein to a different degree. It is the pace of protein turnover that determines, by supplying nitrogen-free residues, the rate of carbon dioxide evolution by this pathway (phase 2).

The main lines of experimental evidence which led to the formulation of Fig. 1 are summarized below and illustrated by some representative data shown in Tables 2 and 3.

(1) The scheme depends first upon the fact that separate metabolic phases exist in the cell. This

Table 2. SPECIFIC ACTIVITY OF THE CARBON IN THE COMBINED AMINO-ACIDS DERIVED FROM VARIOUS ^{14}C-LABELLED SUBSTRATES, PERIOD 5 (109 hr.)

Amino-acid in protein	^{14}C-labelled substrates supplied		
	^{14}C-glucose	^{14}C-glutamine	^{14}C-γ-aminobutyric
Glutamic acid	46	28	8·5
Aspartic acid	43	22	10·2
Alanine	50	2·5	—

Table 3. SPECIFIC ACTIVITY OF THE CARBON IN THE RESPIRED CARBON DIOXIDE AND IN THE COMBINED AMINO-ACIDS DERIVED FROM ^{14}C-LABELLED COMPOUNDS

Period 2 (22–40 hr.). Periods 4 and 5 (61–109 hr.)

^{14}C substrate	Specific activity in sugar in tissue		Specific activity of combined glutamic acid		Specific activity of respired carbon dioxide	
	Period 2	Period 4–5	Period 2	Period 4–5	Period 2	Period 4–5
Glucose—rapidly growing tissue	40–55	71	N.D.	46	46	74
Glucose—slowly growing tissue	26–29	48	low	46	34	76
Glutamine	0	1·4	22	28	18·4	24·6
γ-Aminobutyric	0	1·1	2·3	8·5	7·7	14·1

conclusion follows from the type of evidence presented in Table 1, of which a salient example is as follows: The specific activity data require that there is a source of storage glutamine which is distinct from, and does not mingle with, the glutamine that passes via glutamic acid and other amino-acids into the protein. The specific activity of glutamic acid in the tissue is found to be higher than that of glutamine, which is compatible with a source of inactive glutamine in the cell. Also, the specific activity of the free glutamic acid is approximately that of its source and it is found to remain consistently high throughout the course of the experiment. Therefore, if there is any other glutamic acid that arises during the course of metabolism this must occur elsewhere, for it cannot mingle with the radioactive glutamic acid that is incorporated into the protein; moreover, any such inactive glutamic acid must be rapidly converted to some other form, for example, glutamine.

Since the production of radioactive glutamic acid from the ^{14}C-glutamine supplied has been identified with protein synthesis in phase 1, then the production of inactive glutamine after protein breakdown, which, as indicated, must take place in a separate phase, is therefore identified with phase 2. By the same token, any glutamic acid that arises by protein breakdown also appears in phase 2, and protein breakdown, in contrast to synthesis, is also identified with phase 2.

(2) The specific activity of the free amino-acids in the tissue is not related to the activity of the amino-acids in the protein. Without giving the detail, the specific activities of the amino-acids which acquire ^{14}C-label in the protein tend to be about the same, whereas the specific activity of the free amino-acids vary from one compound to another. The results also show that ^{14}C-glucose was more effective in labelling the protein amino-acids even than such ^{14}C-labelled nitrogen compounds as glutamine and γ-aminobutyric acid. In fact, ^{14}C-labelled glucose actually labelled glutamic acid in the protein more effectively than did ^{14}C-labelled glutamine, which gave rise directly to glutamic acid (see Table 2). Therefore, this is the sort of evidence which leads in Fig. 1 to the suggested use of carbon skeletons, mainly derived from sugar, as the chief source of carbon in the protein synthesized. Furthermore, this feature emphasizes that the anabolic metabolism of glucose to protein is mainly associated with phase 1.

(3) Fig. 1 is also built on the presumption that protein turnover must take place. This conclusion follows because the amount of radioactivity incorporated into certain protein amino-acids, with due regard to the amount of protein synthesized and the specific activity of the carbon source, could not be accounted for apart from alternating protein breakdown and re-synthesis. This point will be discussed later.

(4) The specific activity of the carbon in the evolved carbon dioxide tends to run parallel to the specific activity of the carbon in the protein; but it does not vary directly as the activity of the carbon in sugar; this is especially true of tissue treated with ^{14}C-glutamine and ^{14}C-γ-aminobutyric acid. When the tissue was treated with ^{14}C-labelled glucose, there was a tendency for the specific activity of the carbon in the carbon dioxide to reflect that in the sugar, but in fact it often exceeded this, especially in the later periods of the experiment; but here again the specific activity of carbon in the carbon dioxide reflected that in the protein. All this evidence indicates that part of the carbon dioxide be derived from an alternative source to sugar, and this source may well be protein. However, despite the evidence of protein turnover, there was no conspicuous accumulation of the freed amino-acids; specifically, glutamic acid could not have accumulated (see (1) above), though some glutamine did arise from protein breakdown. Presumably, therefore, the amino-acids that arise from protein breakdown are freely utilized as to their carbon in respiration and as to their nitrogen for re-synthesis of protein.

(5) Whereas some of the amino-acids which arise from protein breakdown might be regarded as re-available for protein synthesis by drift from phase 2 to phase 1, the results require that this could not have occurred appreciably for glutamic acid. Since the conclusions with respect to protein turnover are based on results of radioactivity, this transfer might have occurred with some of the amino-acids which never acquired ^{14}C-label during the experiment; but it could not have occurred to any great extent with respect to those amino-acids which did become so labelled. Also, some of the inactive glutamine which accumulated in phase 2 could have been derived from exogenous sources of nitrogen and from non-radioactive stored sugar. However, this could not have occurred from the sugars present in phase 1 to an appreciable extent, for this would be incompatible with the specific activity data.

(6) When the formation of metabolically active protein is accentuated during growth its synthesis is intimately related to the stimulus to respiratory activity. This will be discussed below.

(To be continued)

[1] The presence of Prof. E W. Yemm, of the University of Bristol, England, as a Visiting Rockefeller Fellow in the Department of Botany at Cornell University provided the occasion for a re-investigation of the use of glutamine and γ-aminobutyric acid by plants and especially by carrot tissue cultures. The facilities for the experiments employing tissue cultures, with and without coconut milk, under the standardized conditions which are required were already well established in this Department and, with the assistance of Miss K. Mears, these facilities were being used in a variety of investigations supported by the National Cancer Institute of the U.S. Department of Health, Education and Welfare. At the planning stage the role of glutamine had been discussed by one of us (F. C. S.) with Prof. G. Krotkov, of the Department of Biology, Queen's University, Kingston, Ontario, and to his interest in the problem we owe the supply of the ^{14}C-labelled substrates which were used. One of us (R. G. S. B.) from the laboratory at Queen's University undertook the responsibility for the radioactive measurements, leading to the specific activity determinations of the various metabolites studied. The necessary chromatographic separations and the use of quantitative paper chromatography and radioautography were carried out in the Department of Botany at Cornell University, and in this work we wish to acknowledge the help of Dr J K. Pollard, Mr. David Margolis and Mrs. Greenwood, all working with one of us (F. C. S.).

Interactions of Ribonucleotide Polymers with Tobacco Mosaic Virus Protein to form Virus-like Particles

THE purified protein and ribonucleic acid constituents of tobacco mosaic virus can be combined *in vitro* to form infectious nucleoprotein rods which resemble the original virus in size and shape and which have their nucleic acid surrounded by protein as in the virus[1]. Although the viral nucleic acid is necessary for infectivity, the formation of rods seems to depend on an inherent property of the viral protein; the latter can be aggregated in the absence of nucleic acid to form cylindrical tubes which superficially resemble the virus[2] but possess no infectivity. When the viral nucleic acid is present, it occupies a region within the tube and apparently serves to 'cement' the protein sub-units together, since the nucleoprotein particles are stable at *p*H values higher than those at which the protein tubes disintegrate[2]. This cementing function might be thought to depend on some property specific to the nucleic acid of tobacco mosaic virus. In order to investigate such a possibility, we have studied the interactions of the viral protein with several widely differing artificial and natural ribonucleotide polymers.

The artificial polymers were gifts from Dr. S. Ochoa and had been prepared by the action of *Azotobacter vinelandii* polynucleotide phosphorylase on various nucleoside diphosphates[3]. They comprised four single-nucleotide polymers containing, respectively, adenylic, cytidylic, uridylic and inosinic acids; and two 'mixed' polymers: adenylic-uridylic acid polymer and a polymer containing the four nucleotides adenylic, guanylic, uridylic and cytidylic acids. From chemical end-group determinations[4], the approximate mean numbers of nucleotide residues per chain have been found to be: adenylic-polymer, 270 residues; adenylic-uridylic-polymer, 120 residues; and adenylic, guanylic, uridylic, cytidylic-polymer, 30 residues.

Two preparations of yeast ribonucleic acid were also tested. One sample, having a molecular weight of the order of 10^5, was a gift from Dr. F. Worthington Allen[5]. The other yeast nucleic acid was prepared by dialysing a commercial sodium nucleate (Schwartz Laboratories, Inc.) against distilled water and collecting the material which passed through the dialysis tubing. A nucleic acid prepared in this way would be expected to consist of chains of the order of five residues in length[6].

The following mononucleotides were also tested as controls: (1) adenosine 5′ diphosphate; and (2) a mixture of the three adenosine monophosphates (2′-, 3′- and 5′-) prepared by mixing 3 parts yeast adenylic acid with 2 parts adenosine 5′ phosphate.

In the reaction mixtures, a solution containing 2 mgm./ml. tobacco mosaic virus protein (prepared by Dr. H. Fraenkel-Conrat[1]) and about 1 mgm./ml. nucleic acid or mononucleotide was brought to 0·03 *M* in acetate by the addition of 3 *M* acetate buffer at *p*H 6. The mixtures were allowed to stand overnight at about 5° and were then dialysed two or more times against distilled water which had been adjusted to *p*H 7·6 ± 0·2 by the addition of sodium hydroxide. Finally, they were centrifuged for 45 min. in a field of $10^5 g$ and the pellets were resuspended in 'Pyrex'-distilled water for examination with the electron microscope.

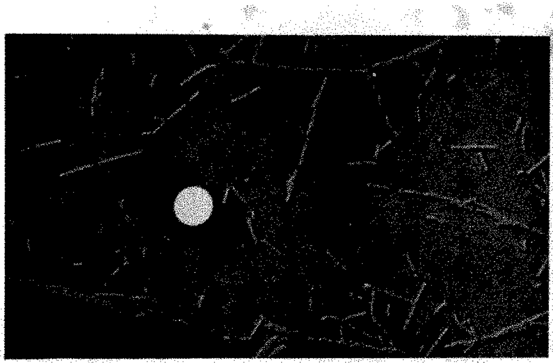

Fig. 1. Nucleoprotein rods made with tobacco mosaic virus protein and a high-molecular weight polymer of uridylic acid. The rods are of the same apparent width as tobacco mosaic virus particles. Included for size comparison is a spherical particle of polystyrene latex having a diameter (260 mμ) nearly equal to the length (300 mμ) of the normal virus particles. × 25,000

All preparations containing any of the nucleotide polymers were found to be aggregated into rods of the same apparent width as tobacco mosaic virus but of various lengths (Fig. 1). The distributions of rod-length appear, from preliminary observations, to be much the same for all the polymers and to be therefore independent of the molecular weight and composition of the ribonucleic acid. The protein without nucleic acid could be made to form similar rods by lowering the *p*H to 6, but all such controls became disaggregated during the dialysis and yielded relatively small centrifugal pellets consisting of disk-shaped particles with central holes[7]. Likewise, the preparations containing mononucleotides failed to yield rods in the pellets.

Ultra-violet absorption measurements of the resuspended pellets indicated that the rods consisted of nucleoproteins resembling tobacco mosaic virus in nucleic acid content. After clarifying several of the resuspensions with alkali (0·01 *M* sodium hydroxide in the presence of 0·06 per cent sodium dodecyl sulphonate), diluting and neutralizing, absorption spectra were obtained which could be graphically resolved into the spectra of the separate protein and nucleic acid components. (Appropriate component spectra were obtained from solutions of the protein and nucleic acids which had been subjected to the same clarification treatments as those used with the nucleoproteins.) These analyses were done for the adenylic- and uridylic-polymer nucleoproteins and for the nucleoprotein made with the high-molecular weight yeast nucleic acid. In each case, the nucleic acid appeared to constitute about 4 per cent of the mass. Direct phosphorus and nitrogen determinations on one sample of adenylic-polymer nucleoprotein indicated a nucleic acid content of approximately 6 per cent The nucleoproteins further resembled tobacco mosaic virus in that incubation with ribonuclease caused no appreciable hydrolysis of the nucleic acid component.

Several of the pellets, resuspended in equal volumes of water, were rubbed on the leaves of various plants to test their ability to produce disease symptoms. The nucleoprotein inocula contained about 0·5 mgm. protein per ml. Those containing adenylic-polymer and adenylic, guanylic, uridylic, cytidylic-polymer were compared with the resuspended pellet from the protein control on opposite half-leaves of *Nicotiana glutinosa* and a variety of *N. tabacum* containing the *N. glutinosa* gene for the production of local lesions (Holmes[8]). None of the preparations gave local lesions on *N. glutinosa*. On the Holmes variety the mean numbers of tobacco mosaic virus lesions per half-leaf were; protein alone, 0·28; protein plus adenylic-polymer, 0·25; protein plus adenylic, guanylic, uridylic, cytidylic-polymer, 0·05. The lesions can be accounted for by a very small virus contamination in the viral protein preparation. (Comparable numbers of lesions are produced by inocula containing tobacco mosaic virus at a mass concentration 10^{-6} times that of the nucleoprotein solutions used here.) No symptoms were produced on *N. tabacum*, var. Turkish, *N. sylvestris*, *Lycopersicum esculentum* or *Datura meteloides*. Preparations containing cytidylic-, inosinic- and uridylic-polymers were tested only on the Holmes variety and also gave no more lesions than could be accounted for by the virus contamination in the protein.

The failure of these nucleoprotein particles to cause disease symptoms is consistent with the current idea that the biological action of a nucleic acid depends on the exact arrangement of its nucleotide residues. The present results indicate, however, that this arrangement may have little to do with the ability of a ribonucleic acid to form stable, organized complexes with protein. In view of the great diversity in the length and composition of the polymers tested, one might conclude that any ribonucleic acid (but not a mononucleotide) would interact with tobacco mosaic virus protein in the same way.

We are grateful for the advice and help of Prof. Robley C. Williams.

Solubilization of Water-insoluble Mucopolysaccharides and a New Method for the Preparation of Blood-Group Substances

STUDIES of native secretions or tissue extracts which contain mucopolysaccharides are frequently difficult because, after isolation and partial purification, a considerable part of the mucopolysaccharide in the original material has become insoluble in water or saline.

This particular change in solubility occurs during the recovery from human and animal tissues and secretions of mucopolysaccharides which possess specific serological properties characteristic of the ABO and 'Lewis' blood group systems. These materials have been most frequently isolated by extracting dried native cyst fluids or tissue extracts with 90 per cent liquid phenol[1], whereas tissues are subjected to peptic hydrolysis to release the specific substances before extraction with phenol[2]. Blood-group materials from either source are mostly found to be insoluble in 90 per cent phenol; but if soluble, as they sometimes are after treatment with pepsin, they are readily precipitated from this solvent with low concentrations of ethanol. The accompanying proteins are soluble in 90 per cent phenol and are readily eliminated.

It is found, however, that group-specific mucopolysaccharides prepared in this way frequently yield material which is only partly soluble in water or saline. Sometimes the water-insoluble moiety constitutes the major part of the substance obtained and in consequence the method of isolation must be considered unsatisfactory. Paramucin, a material of considerable interest as a source of human blood-group substance, occurs naturally as a water-insoluble gel; it is the 'trembling jelly' type of mucin first described by Mitjukoff[3]. Large amounts occur in certain ovarian cysts; but it cannot be brought into solution until partially hydrolysed with acid or alkali, procedures which must be avoided if the original immunological properties of the material are to be preserved. Similarly, serological investigations of human saliva for purposes of certain genetical studies[4] must be made on the whole of the serologically reactive components in the native secretions, and the results must be considered unsatisfactory if only part of the specific mucopolysaccharide complexes contained in the test fluid are soluble in saline and thus available for examination. Water-insoluble forms of the mucopolysaccharides are frequently produced during purification, storage at low temperature and by heat treatment to remove free protein, to inactivate enzymes or to maintain sterility.

It is known that water-insoluble materials of this kind can sometimes be solubilized in strong solutions of urea or certain inorganic salts, like potassium thiocyanate; but in our experience removal of the peptizing agent by dialysis usually results in the recovery of a material which has no greater solubility in water or saline than the starting substance.

It has now been found that these different kinds of water-insoluble mucopolysaccharides can be rendered soluble in water by treatment with ficin, an enzyme preparation from fig latex. When the water-insoluble materials are treated in buffer at *p*H 7 with 0·1–1 per cent by weight of purified ficin, activated with potassium cyanide or cysteine and versene, they dissolve rapidly to yield clear, viscous solutions which retain their blood-group specific characters unimpaired. Group substances obtained after ficin treatment of the water-insoluble materials derived from pseudomucinous ovarian cysts possess the same composition and group-specific serological properties as do substances which are insoluble in phenol and soluble in water obtained from the same cyst material by the usual technique[2]. Prolonged (48 hr.) treatment of purified group substances, isolated without the use of ficin, with large amounts (5–10 per cent w/w) of purified ficin yield materials which show no obvious change in chemical composition or destruction of their original (ABO) group specificity. However, the solubility of the resulting materials in 90 per cent phenol, their lower viscosity and their behaviour in the ultracentrifuge, reveal that the preparations are more polydisperse and have a smaller average molecular size, although remaining electrophoretically homogeneous at *p*H 8. The physical properties of these materials are being studied with our colleague, Dr. R. A. Kekwick, and the underlying process which brings about solubilization of the water-insoluble mucopolysaccharide materials is being further investigated. The lysozyme component of the commercial ficin does not bring about the solubilization of the substances studied.

An alternative procedure which does not involve the use of phenol for the isolation of the specific blood-group substances is long overdue as, with one exception[5], almost all the group-specific mucopolysaccharides described in the literature which have been thoroughly examined by chemical, physical and immunochemical methods have been treated with phenol at some stage in their preparation[6]. The stability of the group substances on treatment with ficin and the powerful proteolytic activity of this enzyme preparation on many proteins prompted us to examine the possibility of using ficin as a means of removing the non-specific protein in native cyst fluids and saliva, and thus allow the specific substance to be recovered from them by dialysis and simple fractionation from aqueous solution by inorganic salts or organic solvents. By the use of ficin it is possible to carry out rapidly at *p*H 7 the isolation of the group-specific materials from tissues and secretions, and the resulting serologically active mucopolysaccharides recovered have the same qualitative composition as, and similar analytical figures to, the materials isolated by the usual phenol-extraction technique. Occasionally cyst fluids have yielded active group materials which possess higher nitrogen values (10–11 per cent) and lower fucose contents (6–7 per cent) than those obtained by the phenol method. Full details of the solubilization of water-insoluble mucopolysaccharides and the alternative method for the preparation of group-specific substances will be given elsewhere.

We wish to thank the Nuffield Foundation for generous financial support. One of us (J. V. M.) is in receipt of a grant from the Medical Research Council.

Independent Requirements for 'Crithidia Factor' and Folic Acid in a Trypanosomid Flagellate

THE trypanosomid parasite of mosquitoes, *Crithidia fasciculata Anopheles* strain (*ATCC* 11745), when grown in a defined medium[1], required for growth unusually high levels of folic acid. In the presence of 'crithidia factor' (an unconjugated pteridine), much lower concentrations of folic acid supported growth; indeed, at times a separate folic acid requirement was not demonstrable[2,3]. Our collaborators at the American Cyanamid Co. have identified the crithidia factor in human urine as 2 : NH_2,4 : OH,6-dihydroxypropyl pteridine[3]. In our experiments reported here, both the 6-dihydroxypropyl and a partially purified sample of the 6-trihydroxypropyl pteridine (generously supplied by Dr. E. L. Patterson) were used.

† Growth expressed as optical density.

By methods previously described[1,2], and with the use of the two pteridines, we have shown that (*a*) both folic acid and crithidia factor are required for growth of *C. fasciculata*; and (*b*) when folic acid is bypassed by supplying thymine, preformed crithidia factor is indispensable (Table 1). Folic acid, when it is the sole source of pteridines, then functions in its usual role in 1-carbon metabolism and is a precursor of a class of pteridines which has an independent function.

There are indications of connexions between riboflavin and pteridine-containing vitamins: (*a*) it has been suggested that *Eremothecium ashbyii* may accumulate a pteridine[4]; (*b*) grasshopper eggs produce a pteridine which replaces riboflavin for the growth of several lactobacilli; the riboflavin content of the eggs decreases as the pteridine content increases[5]. Results with *C. fasciculata* show that while high levels of riboflavin are required when folic acid is the sole source of crithidia factor, in the presence of preformed crithidia factor plus low concentrations of folic acid, riboflavin is spared (Table 2); these results account for the earlier observation[6] that thymine in the presence of high levels of folic acid (when folic acid is the sole source of pteridines) spares riboflavin. Folic acid was not spared by thymine. This may mean that the cleavage of folic acid to yield unconjugated pteridines was not enhanced by thymine.

The wide distribution of crithidia factor in Nature—it is contained in yeast[2], *Drosophila* eyes[7], liver[2,6] and human urine[3]—invites speculation on the

occurrence of growth-factor requirements in other organisms which are satisfied by unconjugated pteridines.

It is not known whether in higher animals folic acid satisfies a multiple requirement. Might such a requirement comprise, besides folic acid itself, a requirement for a pteridine of the crithidia-factor type ?

An enzyme in coliform bacteria cleaves folic acid and its analogues to simple pteridines[8]. The observation that mammalian liver is rich in crithidia factor raises the question of the source of unconjugated pteridine in animals: Does it originate by cleavage of folic acid in the gut or elsewhere, or does it have some other dietary precursor ?

Fig. 1 shows a scheme for the biosynthetic interrelationship among folic acid, riboflavin and crithidia factor. 'Compound *X*' represents the intermediate(s) connecting riboflavin and folic acid pathways.

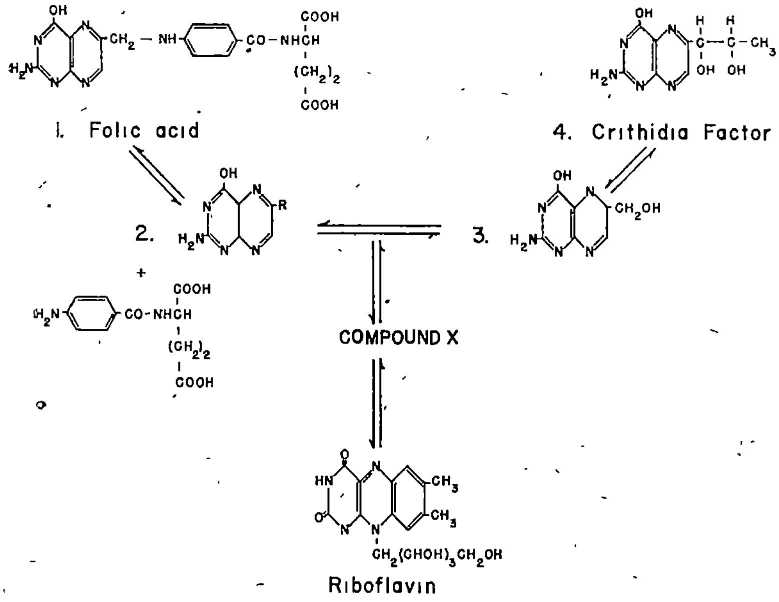

Fig. 1. Proposed scheme of interrelationships of folic acid, riboflavin and crithidia factor. Compound 3 has some crithidia factor activity

This work was assisted by grants from the Rockefeller Foundation, the American Cyanamid Co., the Loomis Institute and the American Cancer Society, on the recommendation of the Committee on Growth, U.S. National Research Council. One of us (H. A. N.) holds a Dazian Foundation Fellowship.

Erythrocytin : an Inhibitor of 8-Hydroxyquinoline ('Oxine') derived from Erythrocytes

8-Hydroxyquinoline ('oxine'), a powerful antibacterial *in vitro*, and 7-allyl-3-aza-oxine are reported to be without chemotherapeutic effect in mice[1]. Their *in vitro* bacteriostatic effects were considerably reduced in the presence of intact, but not of lysed, mammalian erythrocytes[1]. We have now investigated this *in vitro* inactivation of oxine to determine whether it is caused by uptake of the drug by erythrocytes, chemical transformation, or by the liberation of an oxine-inhibiting substance.

Solutions of oxine in normal saline at pH 7·3 were found to lose their antibacterial effect if incubated with washed erythrocytes of many mammalian species, although nearly all the added oxine was shown to be still present in the solutions. A typical experiment using washed rat erythrocytes is described below.

To a solution of oxine (10 ml. containing 0·1 mgm./ml.) in normal saline free from heavy metals at pH 7·3 was added 1 ml. of normal saline free from heavy metals containing 4,000 million washed rat erythrocytes and the system incubated for 1 hr. at 37° C. The cells were then separated by centrifuging. The supernatant was devoid of bactericidal activity, and dilutions (1 in 20) in distilled water, in 0·01 *N* sodium hydroxide, and in distilled water containing an equimolar proportion of ferrous ammonium sulphate were found to exhibit ultra-violet absorption spectra identical with those shown by solutions of oxine under comparable conditions. The spectra indicated that only about 15 per cent of the added oxine had been removed by the erythrocytes, and the rest was unchanged and capable of co-ordination with ferrous ions in a normal manner.

Extraction of the supernatant with chloroform yielded a solid possessing the normal antibacterial activity of oxine and which, as a solid mull in 'Nujol', gave an infra-red spectrum identical with that given by oxine. The remaining aqueous solution was aerated overnight to remove the dissolved chloroform. Solutions prepared by dissolving oxine in this liquid were devoid of antibacterial action; however, heating at 100° C. for 2 min. followed by the addition of oxine yielded solutions with normal antibacterial properties.

Incubation of erythrocytes with normal saline as reported above, but in the absence of oxine, gave supernatants which did not inactivate oxine. Saline solutions of oxine were not inactivated upon incubation with lysed erythrocytes or with washed leucocytes.

The results demonstrate that the inactivation of oxine by erythrocytes is due to the liberation (or production) upon incubation of the cells in presence of the drug of a thermolabile inhibitor which we propose calling 'erythrocytin'. The apparently normal metal-chelating properties of the 'inactivated solutions' are of interest, because it has been suggested that oxine owes its antibacterial action to its ability to penetrate the bacteria as a 2 : 1 complex with iron (or copper) and exert its toxic effects as the 1 : 1 complex[2]. It is possible that erythrocytin might be effective in blocking the penetration of the oxine-iron complex.

We are grateful to Mr. A. A. Vahora for carrying out some of the experimental work, and to Mr. R. Branch for the infra-red determinations. The investigations are being continued, and a full account of the above and other related observations will be published elsewhere.

Bactericidal Action of Oleic Acid against *Mycobacterium avium*

There have been many investigations of the bactericidal action of unsaturated fatty acids against tubercle bacilli[1]; but the mechanism of the effect still remains obscure. I have examined the action of oleic acid on *Mycobacterium avium* (Takeo strain) by Warburg and Thunberg's method, colony count and electron microscope.

The effect of oleate on the colony count was investigated by the ordinary plating method using 'Tween'-agar medium[2], in relation to the concentration and the contact period (Table 1). The cells were killed almost completely after contact with 10^{-3} *M* oleate for 30 min., and with 10^{-4} *M* oleate the viable cells were reduced to 7 per cent. This bactericidal effect was found to depend on the concentration of oleate and the time of contact, and the action was not reversed by washing the treated cells with distilled water.

On the other hand, the oxygen uptake was abnormally enhanced by 10^{-4} *M* oleate, and it was strikingly inhibited below the endogenous uptake by 10^{-3} *M* oleate. With the cell-free crude extract, a different mode of curve was obtained (Fig. 1). The reduction of methylene blue was enhanced by 10^{-5} *M* oleate, and it was inhibited by 10^{-2} *M* oleate. This inhibition was not reversed by washing the treated cells with distilled water; but the cells were able to reduce the dye after grinding them in a ball mill.

From these observations it may be assumed that the bactericidal action of oleate is [illegible] with the surface structures of the cel[illegible] further confirmed by examination in the electron microscope. After treating the cells with 10^{-3} *M* oleate for 60 min., some of their surface structures were disintegrated and their cytoplasmic contents were projected outside the cells. By treating the cells with 10^{-3} *M* oleate, electron-transparent loci were developed, which were located just inside the cell surface; and these seemed to be different from the electron-transparent bodies caused by the intense electron bombardment[3].

Table 1. Bactericidal Effect of Ol[illegible] centration and Perio[illegible]

Contact period	[illegible]
[illegible]	[illegible]

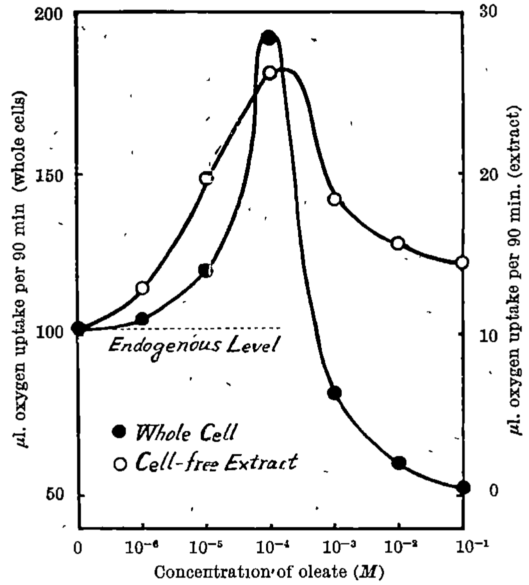

Fig. 1. Effect of concentration of oleate on the oxygen uptake of whole cells and of the cell-free crude water extract

Thus I think that oleate may act at some surface loci of the cell structures, so disintegrating them. Then respiration and reduction of methylene blue are inhibited irreversibly, and the cells are killed.

Progesterone in the Placentæ of Domestic Animals

Progesterone has been isolated from the pre- and post-partum human placenta[1]. It has been assumed, therefore, that it is this placental contribution that enables ovariectomy to be performed during pregnancy without an ensuing abortion. In the mare, cow, ewe and bitch the ovaries may be removed at progesterone[2]. It has also been demonstrated recently that ovariectomy performed on pregnant ewes had no effect on the levels of 'progestin' in the blood, as measured by the Hooker–Forbes bio-assay technique, and the levels in fact continued to rise throughout pregnancy in a manner comparable to that seen in sheep with intact ovaries[3].

The purpose of this study was an attempt to confirm the presence of progesterone in placental tissue by chemical means. Fresh placentæ were obtained from a number of sources, and at various stages throughout pregnancy. They were frozen immediately after collection, and stored in polythene bags at -15° C. until they could be assayed.

The extraction procedure consisted of mincing about a kilogram of the frozen tissue, mixing the mince with sand and kieselguhr, and then pressing it in a small hydraulic press. This yielded about 700 ml. of press-juice, which was hydrolysed in the cold with $0 \cdot 6\,N$ sodium hydroxide and extracted with ether. On evaporating the ether extract to dryness, about a gram of a yellow fatty residue was obtained. This was treated with Girard's reagent *T*, and the crude ketonic fraction thus separated was put through a nine-tube counter-current distribution system of methanol and light petroleum, with a partition coefficient of 1 for pure progesterone. The three central tubes of this system should theoretically contain 71 per cent of the progesterone initially present, whereas most of the other ketosteroids remain in the end tubes. The contents of each tube were then taken to dryness, the material dissolved in absolute ethanol, and examined in an ultra-violet spectrophotometer (Unicam). By measuring the optical density of the solution at 240 mμ, it was possible to obtain a rough estimate of the concentration of progesterone. The ethanolic solutions from the central three tubes were then pooled and concentrated to a small volume for chromatographic analysis. This was carried out on paper strips in a methanol/ligroin system at 37° C. for 2 hr.; using this procedure, progesterone had an R_F value of 0·55. The spots were detected by ultra-violet contact photography, and those with the same R_F value as progesterone were eluted from the paper and re-examined in the spectrophotometer.

By this method it has been possible to detect in the placenta of the mare several hundred micrograms per kilogram of press-juice of a substance which appears to be identical with progesterone, in that it has the same partition coefficient, the same R_F value, the same ultra-violet absorption spectrum and the same infra-red spectrum. As a check on the method, one post-partum human placenta was also assayed, and progesterone was detected readily.

On the other hand, using the same procedure, it has not been possible as yet to detect any progesterone in the late-term placentæ of the cow, ewe, sow or bitch. If, in fact, progesterone is not produced by the placenta in these species, it will be interesting to study the mechanism for the maintenance of pregnancy after ovariectomy, and to investigate further the reported biological activity of cow placental extracts and of blood from pregnant ovariectomized duction of the hormone, or for its selective concentration from the maternal circulation.

I am indebted to Dr. R. K. Callow for carrying out the infra-red analysis, and to Dr. T. Mann and Dr. W. H. Pearlman for helpful advice.

Site of the Chorioallantoic Inhibitor of Influenza Virus Hæmagglutinin

THE chorioallantoic inhibitor of influenza virus hæmagglutinin is destroyed during the multiplication of influenza virus in the allantois[1–3]. It is not, however, destroyed by *V. cholerae* receptor-destroying enzyme inoculated into the allantoic cavity[4], and only partly destroyed when the chorioallantois is exposed to the enzyme *in vitro*[1,4]. Because of this inaccessibility to receptor-destroying enzyme the inhibitor has been taken by most workers to be inside the allantoic cells and therefore potentially an index of the intracellular action of influenza virus enzyme. For example, the finding that massive inocula of virus inactivated by ultra-violet do not destroy the inhibitor has prompted the suggestion[2] that infecting particles lose their enzyme on entering the cell, the only virus enzyme to occur inside cells being that of progeny particles.

Recently, in the course of an investigation of the structure of the allantois, a technique was found for stripping pieces of allantoic endothelium from the chorioallantois. This made it possible to find out if the allantoic cells, even though they constitute less than a tenth of the mass of the chorioallantois, do in fact provide most of the inhibitor. Strips of allantois and the corresponding areas of membrane, free of allantois, were collected from a nine-day embryo. The two tissues were ground, suspended in equal volumes of saline and titrated for inhibitor against heated *LEE* virus[1]. By this test the inhibitor content of the allantois was found to be about one-sixteenth that of the rest of the chorioallantois. A technically easier route to the same result lay in comparing the inhibitor titre of the chorioallantois with that of the allantois covering the yolk sac; large pieces of the latter, containing no major blood vessels, can be stripped off the yolk sac easily and consist of the continuous sheet of allantoic cells backed by only a thin l[illegible]oderm. In several such comparisons [illegible] was found to contain 10–40 times [illegible]a for area, as the allantois. [illegible] per cent of the inhibitor in [illegible]olk sac was shown to be [illegible]n of receptor-destroying enzyme the allantoic cavity. It has yet to be shown: first, that there is any inhibitor inside allantoic cells, and secondly, if there is inhibitor inside the cells, that it is destroyed during virus multiplication.

Precocious Puberty in Rats with Hypothalamic Lesions

It has recently been found[1] that ferrets, normally anœstrous during winter, become œstrous in January and February within 3–4 weeks after electrolytic lesions have been made in the anterior hypothalamus. The hypothesis was advanced that some hypothalamic mechanism may normally inhibit the pituitary secretion of follicle-stimulating hormone in sexually quiescent individuals, for example, (*a*) during the anœstrum of seasonally breeding animals and (*b*) during infancy. Interference with such a mechanism by destruction of hypothalamic tissue might promote the secretion of follicle-stimulating hormone and so induce sexual activity. The suggestion that inhibition of follicle-stimulating hormone secretion is normally exerted during infancy has now been tested on a series of immature rats.

Seventeen 14- or 15-day old females of an inbred Lister strain were used. Electrolytic lesions intended to be immediately posterior to the optic chiasma were made in nine, and eight were sham-operated. The animals were examined regularly post-operatively and the day of opening of the vaginal orifice (which is an index of the occurrence of puberty) recorded. Two lesioned rats reached puberty at 30 days of age and four at 33 days. The vaginal orifice of one sham-operated animal also opened at 33 days. In a comparable group of twenty-six normal rats only one animal had reached puberty at 33 days while the average age for puberty was 41 days (S.D. ± 3·7). Examination of the reproductive tract when the rats were killed at 34–35 days of age confirmed that reproductive maturity had been achieved. Ovulation was found to have occurred in the ovaries of five of the six rats in which the onset of puberty was hastened. Histological studies upon the site of the lesion are in progress.

These findings, together with those on the ferrets, seem to support the hypothesis of a mechanism which inhibits follicle-stimulating hormone residing in the anterior hypothalamus. In man, it has been suggested[2] that such a mechanism is located in the posterior hypothalamus.

Levels of Thyrotrophic and Gonadotrophic Hormones in the Blood of Mature and Immature Female Rabbits

Ten female rabbits were used in this experiment, three immature, three œstrous and four pseudopregnant. The rabbits were rendered pseudopregnant by electrical stimulation of the uterine cervix with a 4·5-V. tetanic current. They were then kept until the eighth day, when the corpus luteum is fully developed[1]. The reproductive state was confirmed by histological examination of the ovaries.

The levels of thyrotrophic and gonadotrophic hormones in the blood of these rabbits were determined by the use of one-day-old chicks[2]. The chicks were injected daily with a subcutaneous injection of 0·50 ml. of plasma for five days. They were then killed by ether 24 hr. after the last injection.

The thyrotrophic hormone level was indicated by its effect on the weight of the thyroid of male chicks, as shown in Table 1. The thyrotrophic hormone in the blood of rabbits is higher during œstrus than during the stages of immaturity or pseudopregnancy. Similar results were obtained in the rat[3].

Table 1. Average Weights of Thyroid and Testes of Chicks injected with Plasma from Immature, Œstrous and Pseudopregnant Rabbits

Treatment	No. of chicks	Average weight of thyroid (mgm./100 gm. body-weight)	Average weight of testis (mgm./100 gm. body-weight)
Control	4	6·11 ± 0·45*	29·46 ± 4·62
Immature	6	6·36 ± 0·47	40·30 ± 2·37
Œstrous	8	11·64 ± 0·73	52·54 ± 4·30
Pseudopregnant	10	9·30 ± 0·53	53·73 ± 4·29

* Standard error.

The gonadotrophic hormone level was indicated by its effect on the weight of the testis of chicks. The gonadotrophic hormone in the blood of mature rabbits (œstrous and pseudopregnant) was higher than that in the immature animal. Lauson *et al.*[4] showed that the gonadotrophic hormone content of the rat pituitary drops rapidly at puberty. They suggested at the time that this may be due to an increased outpouring of the hormone into the blood stream. This view is confirmed by the results obtained in the present investigation. The œstrous and pseudopregnant rabbits did not show a significant difference in the levels of gonadotrophic hormone in their blood. The assay method used did not allow a differentiation between the levels of follicle-stimulating hormone and luteinizing hormone factors.

Mode of Infection of the Nervous System in Poliomyelitis of the Chick Embryo

Inoculation of a chick embryo-adapted MEF_1 strain of poliomyelitis virus into the yolk sac of chick embryos produces an infection which causes lesions like those observed in primates infected with poliomyelitis[1]. Preliminary studies did not reveal the exact mode of spread of the virus from the yolk sac to the nervous system. The present experiments were designed to elucidate this point by correlating the distribution of histological lesions with the concentration of virus in various tissues during the early stages of infection after introduction of poliomyelitis virus by the yolk sac and by the intravenous routes.

Two groups comprising a hundred seven-day, and ninety-five eight-day old white Leghorn embryos were inoculated by the yolk sac and intravenous routes, respectively, with 200,000 and 16,000 mouse *LD*50 units of virus, derived from the 44th egg passage in the series *R* 382 of the chick embryo-adapted strain of MEF_1 poliomyelitis virus[2]. Eggs were incubated at 36° C. and live embryos were harvested at frequent intervals for estimation of the virus in the tissues[1], and for histological study. Embryos were fixed in Bouin's solution and serial coronal sections were made of the entire central nervous system, posterior root, sympathetic and cranial nerve ganglia. All pilot slides made at intervals of 9–29 sections were examined; where lesions were found in a nucleus or ganglion without changes in the corresponding ipsilateral or contralateral ganglion or nucleus, every serial section through the apparently unaffected structure was examined.

Specific lesions of the nervous system, similar to those which have been described in poliomyelitis of the chick embryo[1], were first noted 66 hr. after yolk sac, and 48 hr. after intravenous, inoculation of virus (Table 1). The distribution of lesions was independent of the route of inoculation; but the onset and progress of the pathological changes were considerably accelerated when virus was administered by the intravenous route (Table 1). The Gasserian and spinal ganglia and the nuclei of the sixth and seventh cranial nerves were affected early and frequently. Neuronal cytolysis in the trigeminal ganglion preceded detectable changes in the nucleus of the fifth cranial nerve (Nos. 1–4; 2*A* and 3*A*). On several occasions, no lesions could be found in the geniculate ganglion when severe neuronal degeneration was present in the ipsilateral facial nucleus (Nos. 2, 4, 5, 6, 9; 1*A*–3*A*). In three embryos spinal ganglia were affected and the cord was normal (Nos. 1, 2 and 2*A*). Changes in the jugular ganglion preceded those in the vagal nucleus and the ganglion nodosum (Nos. 5, 6; 1*A* and 2*A*). Lesions were observed on the olfactory bulb 92 hr. after yolk sac infection and 48 hr. after intravenous inoculation of virus. The cœliac ganglia were not affected.

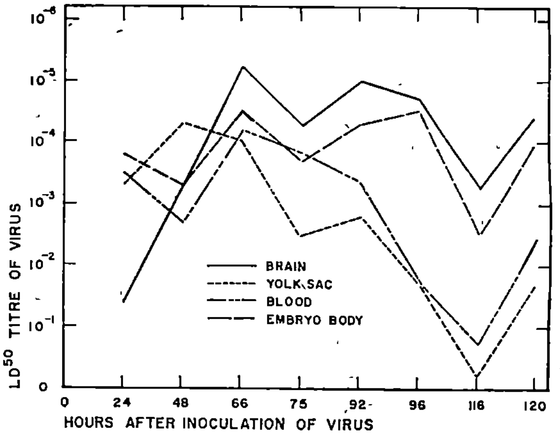

Fig. 1. Distribution of virus in embryos inoculated with 200,000 mouse *LD*50 units of MEF_1 poliomyelitis virus by the yolk sac route. Note the increase in concentration of virus in the yolk sac and the drop in virus titre of the blood and body fractions between 24 and 48 hr. The titre of the blood rose again when that of the brain reached a peak at 66 hr.

Virus which was introduced into the yolk sac multiplied there and initiated a viræmia (Fig. 1); the virus concentration in the brain rose to a maximum 66 hr. after inoculation (Fig. 1), at which time lesions were first noted in the nervous system. When the virus was inoculated into the blood stream, rapid uptake by the nervous system may be inferred from the high virus titre of the brain and low titre of the blood after 24 hr. (Fig. 2); this was confirmed by the earlier development of lesions in this group (Table 1). The more rapid evolution of the disease which followed intravenous infection, the similarity in the distribution of lesions after introduction of virus by either route and the early involvement of unrelated ganglia and nuclei suggest that virus entered the nervous system at several points directly from the blood stream.

Function of the Red Muscle in Fish

During investigations of the vitamin contents of different organs from the tunny (*Thunnus thynnus*)[1], samples from the deep-seated red muscle as well as from the neighbouring ordinary muscle were analysed for niacin, riboflavin, pantothenic acid, vitamin B_{12} and thiamine. The results revealed an interesting relative distribution. With the exception of niacin, which showed a slightly higher value for ordinary muscle, the red muscle contained several times more of the other B-vitamins than the ordinary muscle.

These findings were followed up by investigations of other species. Samples were taken from the ordinary white muscle as well as from the lateral muscle (musculus lateralis superficialis) of several teleosts. The elasmobranch porbeagle (*Lamna cornubica*) has also been included in the investigations. This shark has a distinct red muscle section situated in the middle of the white muscle at both sides of the frontal part of the vertebræ. Some representative results are given in Table 1.

The results showed that, apart from niacin, all the other B-vitamins investigated are present in much higher concentrations in the red than in the ordinary muscle, and further that the general distribution in the red muscle is similar to the values found in the liver.

Chemical analysis revealed that in most fishes the red muscle has a much higher fat-content than the neighbouring ordinary muscle; the values of the present samples from mackerel, herring and halibut were about 27–29 per cent. Muscles with such high fat-contents are scarcely suited for strenuous and continued activities. Assuming the red muscle is the less active, it would be expected that under the anaerobic conditions which prevail during the death struggle, the breakdown of glycogen and the formation of lactic acid would be less in the red than in the neighbouring ordinary muscle. Analysis of the red and the neighbouring ordinary muscle in frozen tunny gave the following interesting values: 1 per cent and traces respectively of glycogen, 0·8 per cent and 1·6 per cent respectively of lactic acid.

The red muscle thus contains relatively high concentrations of the B-vitamins, and also myoglobin[2] and cytochrome *c* [3], which are all part of the enzyme system carrying out oxidative metabolism. It therefore may be concluded that the red muscle is able to carry out similar synthetic processes as those taking place in the liver. If we further consider the relatively frequent high fat-contents in the red muscle, and the fact that the white muscle contains no myoglobin and low contents of the B-vitamins except for niacin, it is likely that the main purpose of the red muscle is not muscular work, but that it functions as an organ.

The exceptional results for niacin, which on an average for the species discussed here was found in equal concentration in both muscles, are in agreement with the special function of this vitamin as part of coenzyme I. This coenzyme plays an important part in carbohydrate metabolism during muscular activity, as well as in several dehydrogenase systems in tissues from different organs. Several enzyme studies are therefore in progress.

Finally, consider the presence of the red muscle in relation to the normal activities of the species. The anatomical situation of the red muscle prevents it taking part in the main muscular work. Further, of the species investigated, the tunny, as a very active and fast-swimming fish, has the highest pro-

Table 1. Vitamin Contents of Liver, Red Muscle and Ordinary Muscle from some Species of Fish

Species	Sample of	Niacin (μgm./gm.)	Pantothenic acid (μgm./gm.)	Riboflavin (μgm./gm.)	Vitamin B_{12} (μgm./gm.)	Thiamine (μgm./gm.)
Tunny (*Thunnus thynnus*)	Liver	87	26·0	46·0	3·10	3·7
	Red muscle	100	32·8	7·9	0·38	4·3
	Ordinary muscle	122	5·0	1·5	0·047	2·5
Mackerel (*Scomber scombrus*)	Liver	79	33·3	11·3	0·52	4·0
	Red muscle	97	30·0	13·8	0·11	3·7
	Ordinary muscle	107	3·8	1·6	0·015	0·2
Halibut (*Hippoglossus hippoglossus*)	Liver	30	9·0	7·0	0·89	2·5
	Red muscle	31	5·2	2·5	0·05	0·35
	Ordinary muscle	44	3·6	0·6	0·009	0·40

portion of red muscle. Next come mackerel and herring, which also move rapidly in shoals. On the other hand, halibut, as a flat fish, has less and a paler red muscle. Further considerations along these lines give the same general relation between activity and the extension and pigmentation of the red muscle in different species.

A fuller account of this work will be published later.

Production of Haploid Plants of Marrow-stem Kale

HAPLOID maize plants have been obtained in frequencies varying between 0·02 and 0·3 per cent by examining seedlings from plants, homozygous for recessive seedling-colour marker genes, which have been pollinated by plants homozygous for dominant marker genes[1]. In marrow-stem kale (*Brassica oleracea* L. var. *acephala* D.C.), it has been found that non-hairy first leaf is recessive to hairy first leaf. Five plants, homozygous for the recessive gene, non-hairy, and obtained from inbreeding a single selection (plant 220), were pollinated in the bud stage by a single plant (31/11), which was homozygous for the dominant gene for hairy first leaf and which was also a first-generation inbred plant. As is shown in Table 1, a total of 2,674 seedling plants were examined and four non-hairy plants were found.

Table 1

Female parent	Male parent	No. seed sown	No. germ.	Per cent germ.	No. hairy	No. non-hairy	No. haploids
220/2	31/11	285	269	95	269	–	–
220/4	31/11	474	295	62	295	–	–
220/6	31/11	240	238	99	237	1	–
220/9	31/11	952	885	93	884	1	1
220/12	31/11	1,006	987	98	985	2	1
	Total	2,957	2,674		2,670	4	2

When these four non-hairy plants came into flower, three had sterile pollen and two of these had much smaller flowers than normal diploid kale. Measurements of stomata showed that the two with small flowers also had relatively small stomata, 22μ and 23μ long, as compared with 28μ long in normal diploid plants.

Cytological examination of pollen mother cells confirmed that the two plants were haploids with a chromosome number of $2n = 9$. A preliminary examination of fifty-four cells at first metaphase showed thirty-eight cells with no bivalents, twelve with one and four with two. The presence of these bivalents is interesting since it has been suggested from the occurrence of secondary pairing of bivalents that the true basic number in the genus *Brassica* is 6, and that in *B. oleracea* itself "three of the six basic chromosomes are present in duplicate, the other three but once each"[2]. The bivalent frequency would also appear to be higher than that in haploid *Brassica campestris* ($2n = 10$), where only occasional cells with one loosely paired bivalent were seen[3].

The occurrence of the two non-hairy plants, which are not haploids, may be due either to accidental self-pollination, diploid egg cells of the female parent functioning without fertilization, spontaneous doubling of original haploid embryos, or mutations in the pollen of the male parent. It may be possible to show that the last hypothesis is the correct explanation by determination of the self-incompatibility allelomorphs present in the two diploid non-hairy plants.

Epidiopatra hupferiana Augener from the North-East Pacific

THE little-known polychaete genus *Epidiopatra*, belonging to the family Eunicidae, was set up by Augener[1] in 1918 to contain two species, *E. hupferiana* and *E. drewinensis*, both collected off the west coast of Africa. No other species has since been added to the genus. The only subsequent record of either species is that of *E. hupferiana* from South Africa by Monro[2] in 1930. Both Augener's and Monro's specimens were dredged on muddy or sandy bottoms and, in Augener's case, mention is made of their inhabiting tubes.

Capture of a specimen of *E. hupferiana* in a plankton tow, from 100 ft. to surface, in Hecate Strait, British Columbia, seems worthy of record. It was taken by Mr. R. J. LeBrasseur, of this Station, in June 1955. The specimen is small (about 12 mm. long) ; but the characters are unmistakable. The generic characters are essentially those of the better-known Eunicid genus *Diopatra*, except that tentacular cirri are entirely absent and there is a very limited number of branchiferous segments. In all technical details the specimen agrees completely with Augener's and Monro's descriptions of *E. hupferiana*.

Two Unifactorial Characters for which Man is Polymorphic

IT has been recognized for many years that humans excrete methanethiol (methyl mercaptan) after eating asparagus, and it has been assumed that this character is universal[1,2]. We have found, however, that while some subjects excrete detectable amounts of methanethiol after ingesting only three or four sticks of asparagus, no significant amount of the compound appears in the urine of others after ingestion of as much as a pound of asparagus. Biochemical investigations of this metabolic difference are being made in collaboration with Dr. P. W. Kent. Nencki's[1]

Table 1

Parental phenotypes	Families tested	Children Excretors	 Non-excretors	Total
Exc. × exc.	1	1	1	2
Exc. × non-exc.	4	5	7	12
Non-exc. × non-exc.	4	0	11	11

identification of the odorous substance in urine as methanethiol has been confirmed by isolation of the corresponding silver mercaptide.

In a random sample of 115 individuals, forty-six were found to be excretors of methanethiol after eating asparagus and sixty-nine were found to be non-excretors. Limited familial data suggest that the excretor character is controlled by a single, autosomal, dominant gene. The offspring of different mating types are summarized in Table 1.

The second character which we have investigated is the appearance of a distinct red coloration in the urine after eating moderate quantities of beetroot. This has been regarded as a rare anomaly occasionally confused with hæmaturia in medical practice. However, in a random sample of 104 subjects, ten reported that they were distinctly positive for this character; another small survey brought to light four matings in which both partners were positive. The six children of these matings are all positive; this result would occur by chance less than once in a million times, and it therefore suggests strongly that the character is controlled by a single, autosomal, recessive gene. Other family data, which accord with this interpretation, are included in Table 2.

The order of frequency of this character implies that about 43 per cent of the population are heterozygous for the gene; hence the expected proportion of non-excretors to excretors in the progeny of cross-matings is just over 3 : 1. As it happened, in both the families tested the non-excretor parent was known to be heterozygous for the gene and the 1 : 1 ratio expected in such back-crosses was obtained. However, the expression of this character appears to be somewhat variable. Most positive subjects develop a typical red urinary pigmentation whenever they eat beetroot; but in a minority the red pigment appears only intermittently, sometimes being replaced by a dark-brown pigment. The red pigment in urine has the same absorption spectrum as the water-soluble beet pigment, betanin, described by Pucher and colleagues[3], which appears to be a polyhydroxyphenolic glucoside containing two atoms of nitrogen per molecule. The brown pigment sometimes found in urine may represent a decomposition product of this rather unstable compound. Dr. R. B. Fisher kindly allows us to quote his finding that the beet pigment is readily absorbed in isolated rat intestines. If betanin is absorbed in all human subjects, its appearance in the urine of about 10 per cent presumably reflects an inability on their part to metabolize the compound. When tested, two excretors of betanin showed no difference from other subjects in glucose re-absorption in the renal tubules.

Table 2

Parental phenotypes	Families tested	Children Excretors	 Non-excretors	Total
Exc. × exc.	3	6	0	6
Exc. × non-exc.	2	2	2	4
Non-exc. × non-exc.	6	2	14	16

It seems that both these characters fall within Ford's definition of polymorphism: "The occurrence together in the same habitat of two or more distinct forms of a species in such proportions that the rarest of them cannot be maintained by recurrent mutation"[4]. If our interpretation of the genetics is correct, in the samples quoted the frequency of the gene controlling methanethiol excretion after eating asparagus, which we propose naming *As*, is 0·23, and the frequency of the gene controlling excretion of beet pigment, for which we propose the symbol *bt*, is 0·31. The fact that these genes and their allelomorphs have remained common in human populations suggests that they are being, or have been, maintained in equilibrium by selective forces which confer an advantage on the heterozygotes. The nature of these forces is at present unknown; but it is possible that, as has already been shown in some blood-groups and hæmoglobin variants[5], the various genotypes differ in respect of susceptibility to disease.

These unifactorial characters identify two additional loci on human chromosomes and should prove of value in tests of genetic linkage.

Anopheles hyrcanus as a Vector of Filariasis in West Bengal

In a recent epidemiological investigation of the filariasis problem in West Bengal, we have frequently detected the Indian form of the species *A. hyrcanus* var. *nigerrimus* as the vector of filariasis, like its counterpart, *A. hyrcanus* var. *sinensis*, in China and Dutch East Indies[1]. It occurs throughout the entire zone from Narayangarh to Ramnagar, covering the four police areas of Belda, Egra, Contai and Ramnagar in the Midnapore District, excepting, however, a single occasion when bancroftian infection was noted in *Culex fatigans* from the suburbs of Contai. Finger blood of residents in every locality of this zone taken at night during the months February–April 1956 showed a mixed infection of microfilariæ of both *Wuchereria bancrofti* and *Wuchereria malayi*, with the latter predominating.

It is generally known that filariasis in India caused by *W. bancrofti* is transmitted by *Culex fatigans*, whereas that caused by *W. malayi* is carried by *Mansonioides annulifera* and to a lesser degree by *M. uniformis* and a few other allied species[2]. Among the anophelines found casually infected in Nature, mention may be made of *A. philippinensis*[3]; but never before has *A. hyrcanus* been incriminated as a natural carrier in India, although the species along with several other anophelines has long been known as a suitable intermediate host of the parasites under experimental conditions[4].

Investigations are progressing and a report embodying further details will be published elsewhere.

Marking of Tsetse Flies for their Detection at Night

Most tsetse field-work so far has been based on day-time observations of active flies. If work is to be done on resting flies, it will be advantageous to have an easy method of locating them. It is known[1] that mosquitoes can be dusted with non-toxic materials which fluoresce in ultra-violet light at night, and using this method, mosquitoes can be watched at a distance of about 10 ft. The insects are not sensitive to ultra-violet radiations.

Much experience has been gained of marking the thorax of tsetse with oil paints in the field[2], and this method of applying the fluorescent paints would have many advantages. Luminous paint of the type that shines without excitation by ultra-violet radiation proved (*a*) poisonous to tsetse and (*b*) to give too feeble a glow to be useful under field-conditions.

B.T.H. 'Dayglo' (silica-based organic dyes in ethyl cellulose) powders mixed with a binder and solvent produced a satisfactory paint and were used in a series of tests on house and tsetse flies. The ultra-violet lamp used was worked off 230 volts a.c. It is of interest to note here that a source of ultra-violet radiation has been developed which can be worked off a 6-volt battery. Paint was applied with a sharpened match-stick on the centre of the thorax, covering it without fouling head or wings.

At 15 ft., treated flies shone brilliantly in the ultra-violet beam and the maximum range was 20 ft. The lamp produced much visible light, and the maximum range might well be increased by filtering out the glare. 'Dayglo' paints, when excited by ultra-violet radiation, have a visible glow from 8 ft. in daylight. The ultra-violet light does not appear unduly to disturb *Glossina morsitans*.

Thus there appears to be a promise of success for locating tsetse flies at night by painting the thorax with non-toxic materials which fluoresce under ultra-violet light.

These experiments were carried out in the Department of Entomology at the London School of Hygiene and Tropical Medicine, and I should like to thank Dr. Bertram for allowing the use of the facilities of his Department, Messrs. W. H. Potts and E. F. Whiteside for help and the British Thomson-Houston Co., Ltd., for the supply of materials and demonstration of ultra-violet sources.

Mortality in the Sheep Ked, *Melophagus ovinus* (L.), caused by *Trypanosoma melophagium* Flu.

The sheep ked is an obligate blood-sucking ectoparasite of sheep ; its life-history is well known and has been described by various authors, notably Evans[1]. Hoare[2] has described the life-history of *Trypanosoma melophagium* Flu. and its relation to the ked. The crithidial stage of the flagellate is a normal inhabitant of the midgut of the insect. Crithidia are attached by their flagella to the epithelium of the posterior half of the midgut, and small numbers may be found in the gut lumen. Small masses of the metacyclic, or infective, stage may be seen adhering to the wall of the iliac bulb (rectum) or free in the contents of the bulb.

At the Lethbridge Laboratory, large numbers of keds have often been seen to die on sheep as a result of blockage of the posterior midgut by large masses of crithidia. The gross symptoms of impending death are usually (*a*) swelling of the abdomen, (*b*) development of a reddish-pink colour over the entire insect (indicating escape of sheep's red-blood cells from the gut into the hæmolymph), (*c*) change in colour from brown to white of the iliac bulb, which is distended, violently contracting, and clearly visible through the dorsal integument.

Internally, although the anterior midgut is distended with undigested blood, the posterior midgut is emptied of digestive contents between the pyloric valve and the mycetome. Microscopically, in this region are seen, in addition to crithidia attached to the gut wall, masses of crithidial rosettes that are packed into the lumen. Smears of the iliac bulb contents show large numbers of metacyclic forms mixed with excretory products from the Malpighian tubules. The tubules themselves appear greatly distended ; but rarely do they contain any stages of trypanosomes.

Survival of Normal Rabbits after Appendectomy

The majority of the lymphoid tissue in the alimentary canal of normal rabbits is in the appendix, which in fact contains about a half of the total body complement[1]. It forms an active lymphoepithelial system[2] which interchanges bacterial and tissue cells with the gut lumen.

Different aspects of this process have been shown to have immunological[3] and nutritional significance (ref. 1 and unpublished observations on absorption of radioactive bacteria) ; but I have not found any publication on the results of curtailing them by

Table 1

No.	Initial weight (gm.)	Date of appendectomy	Date of death	Weight at death (gm.)
32	4.11.52 2,335	10.11.52	23 5.56	2,950
34	4 11.52 2,305	not operated	killed 23.5.56	2,650
36	4.11.52 3,160	13.11.52	26.8.55	3,650
37	13.11.52 3,333	not operated	16 1.53	3,620

appendectomy. I have done this on several dozen rabbits, and they are apparently unaffected by it. Table 1 shows the result of a small controlled survival experiment on stock adult albino rabbits maintained at Guy's Hospital Medical School, which confirms this impression.

Some Properties of Extracted Protochlorophyll Holochrome

MANY leaf pigments have very different spectral, solubility and physiological properties when in the leaf from those shown when they are extracted and dissolved in organic solvents. Because of this, the pigments in the leaf are assumed to be bound to other substances, probably proteins. This combination has been termed holochrome[1]. As the derivation indicates, the word means complete pigment and designates the pigment as it is combined in the leaf.

In etiolated leaves, protochlorophyll holochrome is transformed by light to chlorophyll-*a* holochrome, whereas isolated protochlorophyll itself is not so transformed (cf. ref. 1). Recently, protochlorophyll has been extracted from dark-grown leaves with glycerine[2] and with buffer solutions[3] in a form that is transformed to chlorophyll *a* by light. This result indicates that protochlorophyll can be separated from the leaf in its holochromatic form. We have endeavoured, therefore, to isolate and characterize the minimum unit of the protochlorophyll complex which can carry on this photochemical transformation.

A partial isolation of an active protochlorophyll complex has been accomplished as follows: bean seedlings (*Phaseolus vulgaris*, var. Blue Lake, Ferry-Morse Seed Co.) were grown in a dark room at about 20–22° C. The etiolated leaves (10 gm.) 10–12 days old were ground in a mortar for 10 min. with 30 ml. of a solution of glycine (0·1 *M*) and potassium hydroxide (0·05 *N*) at *p*H about 9·6. The grinding was done in a dark cold room at about 6° C. The liquid was squeezed through a fine-woven cloth and centrifuged at 10,000 *g* for 15 min. The supernatant was pressed through a French–Milner homogenizer[4] with a pressure of 20,000 lb./sq. in. The homogenate was centrifuged for 1 hr. at 10,000 *g* and the supernatant dialysed in Visking tubing overnight against glycine buffer. The dialysed extract was centrifuged in a Spinco Model *L* centrifuge at 40,000 r.p.m. (approximately 93,000 *g*) for 3 hr.

The pellet contained a much greater proportion of the active protochlorophyll than did the supernatant. The pellet was dissolved in a portion of the glycine buffer solution. This required thorough stirring and standing for several hours. Illumination of the dissolved pellet produced chlorophyll *a* (cf. Fig. 1). Sedimentation analysis of this solution by means of a Spinco Model *E* ultracentrifuge showed the presence of two well-separated boundaries (cf. Fig. 1, inset) with sedimentation coefficients of about 4 and 16 Svedberg units respectively. The faster-moving of these boundaries was correlated with the active protochlorophyll complex. Sedimentation diagrams of the extract made before obtaining the pellet showed a much greater proportion of the slower-moving boundary than did those of the resuspended pellet (cf. Fig. 1, inset).

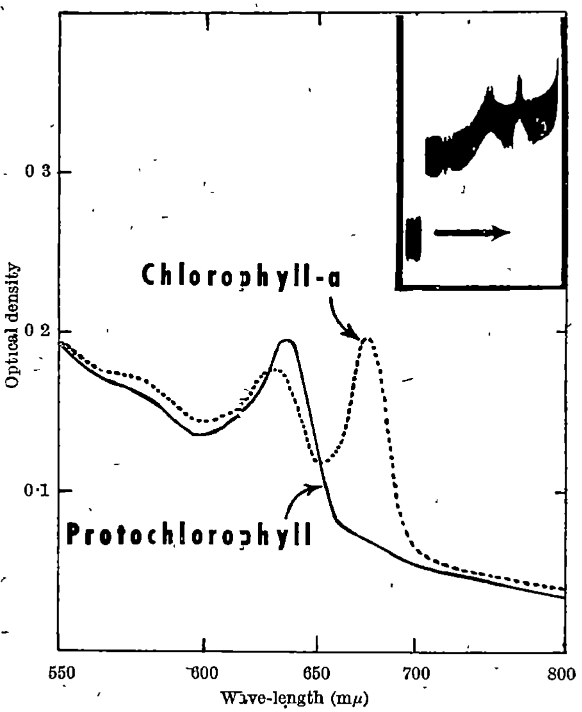

Fig. 1. Absorption spectra of the dissolved pellet, obtained by centrifuging at 40,000 r.p.m. a dialysed extract of etiolated bean leaves before (solid line) and after (broken line) being illuminated. Inset: Sedimentation pattern at 50,740 r.p.m. in synthetic boundary cell Leading boundary is associated with the photo-transformed material; the trailing peak is near the initial synthetic boundary

In the analytical ultracentrifuge, the solutions were of necessity illuminated. The following observations, therefore, relate to the derived chlorophyll-*a* complex.

No obvious heterogeneity in particle size was indicated, since the spreading of the leading boundary during sedimentation was not extensive and appeared to be symmetrical. The sedimentation coefficients (s_{20}) obtained for several preparations, and measured at different stages of preparation, ranged from 15·3 to 16·2 Svedberg units. The boundary showed no artificial sharpening, nor did its rate of movement depend significantly on the concentration of the solution. Comparison of the s_{20} values with those published for various globular proteins suggests that the molecular weight of this protochlorophyll complex is about 400,000.

In other experiments, subsequent to dialysis against glycine buffer, the extract was further dialysed rapidly against several changes of distilled water and then lyophilized. The solid obtained was slightly yellow and was readily dissolved in aqueous solutions above *p*H 6. Such solutions exhibited the characteristic absorption spectrum in the red of protochlorophyll holochrome and, after being illuminated, that of chlorophyll-*a* holochrome. In the blue region of the spectrum the characteristic absorption of these pigments was not distinguishable owing to the presence of yellow pigments. The solid material was stable for months when kept in a darkened cold-room. Obviously, no diffusible co-factor is necessary for this photo-conversion.

The lyophilized solid material did not give up its protochlorophyll when extracted with absolute acetone. When aqueous acetone was used, however, the pigment was extracted.

Although the particles containing the active protochlorophyll have not been isolated in pure form, various tests indicate that they consist largely of protein.

From these experiments it may be concluded that a fraction has been separated from etiolated leaves which contains particles of uniform size that possess properties similar to those of native protochlorophyll holochrome in respect to spectral absorption, pigment solubility, and photo-conversion to chlorophyll-*a* holochrome.

In a recent issue of *Nature*[5], J. W. Lyttleton directed attention to two cytoplasmic protein fractions of leaves which had been obtained by Wildman and his co-workers[6]. These fractions possessed sedimentation coefficients, s_{20}, of 3–4 and 16–17 Svedberg units respectively. Lyttleton's own results suggested that the faster-moving fraction "is found only in photosynthesizing tissue or in tissue which is capable of photosynthesis after it is exposed to light". It is instructive to note that we have obtained two similar fractions from etiolated bean leaves, and that the faster sedimenting of these contains protochlorophyll attached in such a way as to be converted by light to chlorophyll *a*. This observation likewise suggests a role for this fraction in photosynthesis.

We are grateful to the Chemistry Department of Stanford University for making available the Spinco centrifuges for this work. During the first part of this investigation, one of us (D. W. K.) was associated with the Chemistry Department of Stanford University as a Fellow of the U.S. Public Health Service.

Occurrence of the Methylene-dioxy Bridge in the Phenolic Components of Plants

The methylene-dioxy bridge  $\left(\begin{smallmatrix}-\mathrm{O}\\ -\mathrm{O}\end{smallmatrix}\!\!>\mathrm{CH_2}\right)$ is a common feature of the structure of several groups of plant alkaloids and occurs also, though less commonly, among natural phenolic substances. Geissman and Hinreiner[1], in a recent review of natural phenols, list twenty-four different substances containing the methylene-dioxy bridge; fourteen of them are C_6—C_3 type and all are characterized by a generally high degree of methylation of hydroxyl groups in the molecule; indeed, none of them bears a free hydroxyl in the ring that bears the bridge. The alkaloids are similarly characterized by a high degree of methylation of phenolic hydroxyl groups[2]. Botanically, the methylene-dioxy phenolic substances are distributed widely but not haphazardly, for they occur in six families of Polypetalae (Anonaceae, Magnoliaceae, Rutaceae, Leguminosae, Rosaceae and Umbelliferae), three of Apetalae (Myristicaceae, Lauraceae and Piperaceae) and one of the monocotyledons (Orchidaceae). Of these families, Lauraceae and Piperaceae are much the most abundant sources, and it seems from this (as from the occurrences in Magnoliaceae, Rutaceae, Umbelliferae and Myristicaceae) that there may be some relationship between aromatic properties and the occurrence of the bridge. It may be significant, too, that of the eleven families of plants which have yielded methylene-dioxy alkaloids, no fewer than four occur in the above list of phenolic-bearing families (Anonaceae, Rutaceae, Leguminosae and Piperaceae[2]).

In a general survey of phenolic substances in the leaves of plants, Bate-Smith[3,4] recommends the use of a toluene/acetic acid/water solvent for chromatography; this solvent has the useful property of immobilizing the commoner natural phenols except the cinnamic acids (ferulic, sinapic and *p*-coumaric) and the related coumarins (scopoletin and umbelliferone). Of these substances, ferulic acid, R_F 0·25, is the most mobile, so that the lower portion of the chromatogram is commonly empty. Occasionally, however, leaf extracts are encountered which yield blue spots giving violet or green fluorescence under ultra-violet light, that run in advance of ferulic acid. Apart from the uncommon 7-methoxycoumarin, herniarin, which, we are informed (personal communication from Dr. E. C. Bate-Smith), has R_F 0·9 approximately in the toluene/acetic acid/water solvent and has a deep-violet fluorescence under ultra-violet light, it is very difficult to make any plausible guesses as to their identities.

It now seems that the occurrence of methylene-dioxy bridges may furnish at least a partial explanation of these fast-moving spots. In support of this statement are the following experimental results. 3 : 4-Methylene-dioxy cinnamic acid was prepared from piperonal by a Dobner condensation (Johnson[5]; melting point 234°–36° (uncorr.); Johnson gives melting point as 233° (corr.)). It gave the following R_F values (corrected by R_M values to known standards run on the same paper[3]): in the Forestal solvent (hydrochloric acid, 10/acetic acid, 100/water, 30), 0·93; in toluene/acetic acid/water (40 : 10 : 50), 0·86; in butanol/acetic acid/water (40 : 10 : 50), 0·89. Under ultra-violet light, it fluoresced dull violet; it was light blue in acid vapour and faded until almost invisible in ammonia. It did not react with diazotized *p*-nitroaniline, whereas herniarin gives a yellow colour with this reagent[6]. A substance which agreed precisely in its R_F in all three solvents and in its ultra-violet fluorescence colours was found in the leaves of *Piper tuberculatum*. If these results be accepted as provisional proof of identity, then this is at once the first record of natural occurrence of the substance and a demonstration of the nature of one of the uncommon fast-moving phenolics in plant extracts. It is surely significant that it occurred in the Piperaceae—the plant, indeed, was chosen for investigation on the basis of the introductory remarks made above. A limited survey of the leaves of plants representing families in which methylene-dioxy bridges are known to occur yielded the following results (numbers of 'fast phenolic' spots in the toluene/acetic solvent are given in brackets):

Family	Results
Magnoliaceae :	*Magnolia grandiflora* (0)
Anonaceae :	*Canangium odoratum* (0) ; *Monodora grandiflora* (0)
Rutaceae :	*Murraya exotica* (4) ; *Citrus aurantifolia* (1) ; *Citrus paradisi* (1)
Umbelliferae :	*Eryngium foetidum* (0)
Lauraceae :	*Persea gratissima* (0) ; *Cinnamomum camphora* (0)
Piperaceae :	*Piper tuberculatum* (2) ; *Piper marginatum* (3) ; *Piper nigrum* (0) ; *Pothomorphe peltata* (0) ; *Peperomia pellucida* (0)

The Practical Synthesis of I-Phenazinol

Considerable interest has been aroused in 1-phenazinol because of its relatively high antibiotic activity, as brought out in numerous reports, such as in that by Zweig[1]. The methods generally advocated for its preparation, however, are not very satisfactory. Thus the procedures of Surrey[2], and of Hegedüs[3], are time-consuming, while the preparation through pyocyanine obtained from *Pseudomonas pyocyanea* cultures suffers from low yield of the pyocyanine[1]. Poor yield, in this instance of the intermediate 1-methoxyphenazine, also hampers the preparation of 1-phenazinol given by Yoshioka[4].

It has been found that two procedures, already well known in the literature, can be conveniently combined to give a practical means of preparing 1-phenazinol. Phenazine, now readily available by purchase or by synthesis[5], is combined with dimethyl sulphate to produce the quaternary salt, and from this pyocyanine is formed by McIlwain's photochemical synthesis[6]. The pyocyanine, without being isolated, is then converted to 1-phenazinol by the method of Wrede and Strack[7].

The details of the procedure are as follows.

Preparation of 5-methylphenazinium methyl sulphate (phenazine methosulphate). For the sake of completeness, what is essentially the method of Kehrmann and Havas[8] is detailed here. A solution of 25 gm. of phenazine in 125 c.c. of nitrobenzene was heated to about 130° and when it had cooled to 120° it was immersed in an oil-bath heated to 115°. Then, all at one time, 35 c.c. of freshly distilled dimethyl sulphate was added, with stirring. The stirred mixture was kept at 105–10° for five minutes, then removed from the bath. Spontaneous precipitation on cooling gave 35 gm. of bright orange crystals, after removal of adherent nitrobenzene by anhydrous ether.

Conversion to 1-phenazinol. A solution of 4·3 gm. of the unrecrystallized methosulphate in 3·5 litres of distilled water[6] was exposed in an open flask to sunlight through a window for three days, during which the Sun was unclouded for about two-thirds of the time. Then a solution of 80 gm. of sodium hydroxide in about 250 c.c. of water was stirred in, and the reaction mixture allowed to stand for 16 hr. Filtration through fine porosity paper and one extraction with ether were then employed to remove the phenazine and other by-products of the reaction. The aqueous solution was next made faintly acid with glacial acetic acid, and extracted twice with ether. Evaporation of the ether left 1·5 gm. of crude 1-phenazinol. This was purified by slow vacuum sublimation at about 0·1 mm. from an oil-bath at 115°, giving 1·1 gm. of 1-phenazinol, shrinking at 158·6°, and melting at 159–160° (corr.). The yield of the pure product is 33 per cent, based on the phenazine, and 40 per cent, based on the methosulphate.

(To determine the effect of lessening the large volume, 4·3 gm. of phenazine methosulphate was dissolved in 1 litre of water, and subjected to the same treatment as was given to the more dilute solution. In this instance only 0·94 gm. of crude 1-phenazinol was obtained. It was not determined whether longer exposure to sunlight would increase the yield from this more concentrated solution.)

Observation of Atmospheric Sodium in Absorption

Nearly twenty years ago, the presence of sodium in the upper atmosphere was found by the observation of the *D* lines in twilight[1]. Attempts to deduce the amount of sodium in the layer suffer from an unknown correction for self-absorption[2]. It is therefore of interest to try to observe the sodium by its absorption; but this is difficult with sunlight because of the strong Fraunhöfer lines originating in the Sun itself. An attempt was made by Sanford[3] using the star α Virginis as a source; here the stellar and interstellar *D* lines are shifted by the Doppler effect so that they do not interfere. He found a faint line which may have been telluric *D*1, and deduced a corresponding upper limit of $1\cdot0 \times 10^{10}$ atoms/cm.^{2} for the 'thickness' of the layer, as we may call it.

To observe the telluric absorption in sunlight an instrument is needed giving high resolution and little stray light. We have achieved these by making use of resonance scattering by sodium vapour at a temperature of about 150° C.; the scattered light is recorded by a photoelectric spectrometer[4] which separates the two *D* lines. The system is calibrated by means of light from a tungsten lamp, which, of course, has no absorption lines. The result is a value of the intensity at the bottom of each *D* line as a fraction of the nearby continuum. Between noon and sunset the path-length through the sodium layer varies by a factor of 2–3, depending on the season. A slight decrease in the residual intensities was in fact observed. Two tests showed that the effect was due to sodium rather than water vapour, which has many lines in the yellow. The variation in $D1$ was less than that in $D2$ by a factor averaging 0·59, which compares well with the expected 0·50. A large drop in the absorption was found in April compared with January and February; this agrees with the behaviour of sodium observed in twilight[2] but disagrees strongly with the behaviour of water vapour.

The thickness of the sodium layer was found from the slope of a plot of logarithm of intensity against relative path-length. Eleven of these from the months December, January and February gave thicknesses between 2·5 and 8·3 × 10^9 atoms/cm.^{2}; twilight observations give about 3 × 10^9. Two in April gave 1·06 and 0·88 × 10^9 atoms/cm.^{2}, in good agreement with twilight observations. It may be concluded that twilight intensities are lowered appreciably by self-absorption in winter but by no more than a factor of about 2.

The plots may be extrapolated to zero path-length to give the residual intensity of the solar D line, averaged over the whole of the Sun's disk. Our results are (5·9 ± 0·46) per cent for $D1$ and (5·06 ± 0·24) per cent for $D2$, in fair agreement with previous work[5].

Hydrogen Isotope Exchange

There appears to be some confusion[1–3] in the derivation and application of certain relationships featuring the separation factor for hydrogen (H) and deuterium (D) chemical-exchange processes.

(1) *Derivation of equations.* Consider the following general reaction involving chemical exchange between isotopes I and I'. Let only n_2 of the total n_1 atoms of I and I' in the compound with A be exchangeable, that is, n_4 atoms of I are fixed, and assume that the concentration of I' is very small:

$$\underset{(a)}{AI_{n_4}I_{n_2}} + \underset{(b)}{BI_{n_3-1}I'} \rightleftharpoons \underset{(c)}{AI_{n_4}I'_{n_2-1}} + \underset{(d)}{BI_{n_3}} \qquad (1)$$

where $(n_4 + n_2) = n_1$.

If a, b, c and d ($d \gg b$ and $a \gg c$) denote the concentrations of the respective molecular species in the reaction, the equilibrium constant K_s is given by:

$$K_s = \frac{c.d}{a.b} \qquad (2)$$

The separation factor α may be defined by the ratio,

$$\alpha = (I'/I)_A/(I'/I)_B \qquad (3)$$

but this requires amplification. Thus, the value α_1 based on the total number of I, I' atoms present in compound A is different from the value α_2 based on only the exchangeable atoms. For the former case (which is the more useful since experimental analysis usually includes all atoms I and I') it is seen from equation (1) that,

$$(I'/I)_A = \frac{c}{a(n_4+n_2)+c(n_4+n_2-1)} \rightarrow \frac{c}{a(n_4+n_2)}$$

$$(I'/I)_B = \frac{b}{dn_3+b(n_3-1)} \rightarrow \frac{b}{dn_3}$$

which in combination with equations (2) and (3) give

$$\alpha_1 = \frac{c.d.n_3}{a.b.(n_4+n_2)} = \frac{n_3}{n_1} . K_s \qquad (4)$$

Similarly, α_2 may be obtained as:

$$\alpha_2 = \frac{n_3}{n_2} . K_s \qquad (5)$$

Clearly, if all sites in compound A are exchangeable, that is, if $n_4 = 0$, then α_2 will be identical with α_1; and if the distribution of I and I' be uniform, then α_2 (by definition) will be close to unity.

The equilibrium constant in the above equations may be replaced by the quantum statistical relationship:

$$K_s = \left(\frac{\text{Reactants}}{\pi\sigma} \Big/ \frac{\text{Products}}{\pi\sigma}\right) . f(\nu) \qquad (6)$$

where π is the multiplication operator, σ is the symmetry number (which for any one of the molecules taking part is the number of equivalent orientations in space that that molecule can assume as the results of simple rotation) and $f(\nu)$, which generally tends to the value unity when heavy molecules and moderate temperatures are considered, is a function of the vibrational frequencies.

(2) *Equivalence of position.* It has been assumed that all sites in compound A which partake in exchange are identical. If these positions are not equivalent, for example, if different types of bond or force constant are involved (as in equation 6), then the equations are not strictly applicable.

(3) *Molecular symmetry.* Molecular symmetry is of no importance in deriving equations (3) and (5), and only the numbers of similar sites available for, or excluded from, exchange are concerned[4]. Thus, the equation presented by Gold and Satchell[1], namely:

$$\alpha_2 = \left(\frac{\text{Products}}{\pi\sigma} \Big/ \frac{\text{Reactants}}{\pi\sigma}\right) . K_s \qquad (7)$$

does not represent the general case. Only if both the n_2 exchange sites in the molecule and the molecule $AI_{n_4}.I'_{n_2}$ itself are symmetrical (for example, the three H atoms in ammonia or the two H atoms in aniline) is equation (7) identical with equation (5). In many instances, this condition is not satisfied. For example, by use of a suitable substituent, a nuclear mono-substituted aniline may be obtained which although asymmetrical still possesses two identical amino-group hydrogen atoms capable of exchange. It can be seen that, in this case, equations (5) and (7) differ by a factor of two.

(4) *Application: simple cases.* Consider reactions of the type,

$$AH_{n_4}H_{n_2} + HDO \rightleftharpoons AH_{n_4}H_{n_2-1}D + H_2O \qquad (8)$$

Under mild conditions at 25° C., it has been found[2] for amyl alcohol ($AH_{n_4}H_{n_2} = C_5H_{11}.OH$) that

$\alpha_1 = 0\cdot0912$, and for phenol[3] ($C_6H_5.OH$) that $\alpha_1 = 0\cdot1824$. On applying equation (4), both these results give $K_S = 0\cdot55$ (expected from equation (6) for asymmetric molecules), and from equation (5), assuming only the hydroxyl-H atom exchangeable, the corresponding value of α_2 is $\alpha_2 = 1\cdot10$ (see section (1) above). It is seen that for mono-functional cases[1] $\alpha_2 = 2K_S \simeq 1\cdot0$.

For benzene[3], where six identical H atoms are capable of exchange, equations (4) and (5) give $\alpha_1 = \alpha_2 = K_S/3 = 1\cdot0$.

Values of α_1 are of significance in preparing labelled compounds or in separating hydrogen from deuterium. For example, in the above cases, a D/H ratio equal to that of the water can be obtained in the benzene, whereas only a tenth of this ratio can be secured in the amyl alcohol.

(5) *Application : nuclear aromatic exchange.* Under certain conditions, a substituted benzene compound, for example, phenol, may exhibit slow nuclear deuteration in addition to rapid exchange of the functional hydrogen atom (in this case, the hydroxyl-hydrogen atom) and it is required to know what positions are being affected.

In sections (1) and (4) above, it was shown that $\alpha_2 = f(\nu) \simeq 1\cdot0$ for H/D exchange at certain O—H and C—H positions (compare S—H bonds[1]). If it is assumed that substitution of benzene has little effect upon the vibrational frequencies (see sections (1) and (2) above), then α_2 will remain equal to unity for the H/D distribution in the nucleus of the deuterated phenol. Thus, after methylation to yield the nuclear-deuterated anisole ($AH_{8-n_3}.D_{n_3}$), that is, elimination of the deuterated hydroxyl group, a value of α_1 of $0\cdot342$ is obtained[3]. From this figure, K_S is $1\cdot37$ (compare ref. 1) and, assuming $\alpha_2 = 1\cdot0$, the corresponding value of n_3 is $2\cdot74$; hence, three nuclear positions (presumably the *ortho-* and *para-* sites) are capable of exchange.

It should be noted[3] that, in these operations, it is α_2, and not α_1 or K_S, which is placed equal to unity.

Deformations of Metal Surfaces under Normal and Inclined Loads

THE purpose of this communication is to offer an explanation of why oxide and other protective films, as measurements of electrical resistance[1] and transfer[2] have shown, are less disrupted when two metal surfaces are loaded together normally than when the loading has a tangential component and the surfaces slip. The suggested explanation is that under normal loading, even though the surfaces be permanently dented, there is a surface layer of material which is not plastically deformed, whereas if the loading be sufficiently inclined the plastic deformation extends to the surface.

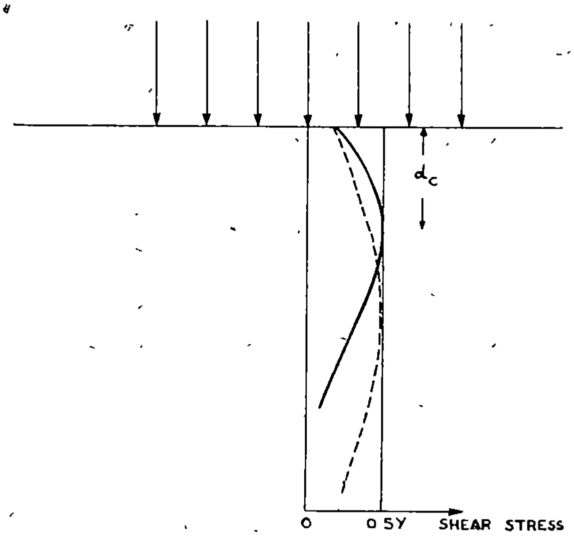

Fig. 1. The variation of the shear stress with depth when the loading is normal

It is a result of the theory of the contact of elastic bodies in circumstances of normal loading[3] that the stress responsible for plastic yielding, which will here be taken as the maximum shear stress, has a value proportional to the mean pressure over the area of contact and occurs at a depth proportional to a dimension of that area. The variation of the shear stress with depth is illustrated in Fig. 1. The full line indicates the shear stress at the limiting normal load for elastic conditions, P_C. Plastic deformation is imminent at a point d_C beneath the surface where the maximum shear stress has reached half the yield stress (Y) of the material. Let it be assumed that when the load exceeds P_C the nature of the stress field remains the same, in particular that the maximum stress still occurs at a depth proportional to the pertinent dimension of the contact area, and that because of the flow, the maximum of the shear stress is limited to $0\cdot5\,Y$. The variation of shear stress with depth which then exists is illustrated by the dotted line in the figure. Clearly, as the load, area of contact and therefore the depth of the point of maximum stress increase, the stresses in the region from the surface to the depth d_C decrease. Consequently, this region is always protected from plastic yielding and there is a surface layer which is not plastically deformed.

Poritsky[4] has calculated the stresses which exist in cylinders making line contact when the loading is inclined. Under purely normal loading the shear stress perpendicular to the line of contact is zero at the surface while with a sufficient tangential component this stress is very close to the maximum shear stress. In the latter circumstance an undeformed surface layer is not to be expected.

It follows from the above argument that the protective surface films are less disrupted when the loading is normal; indeed, they may not be broken at all. In addition to providing an explanation of the resistance and transfer experiments already referred to, this also affords an explanation of the lack of adhesion between normally loaded metal bodies when their surfaces are contaminated[5] and provides a reason why a tangential force is needed to induce the formation of welds[6].

Direct metallographic evidence of the undeformed layer has been obtained from mild steel disks run together at a load in excess of that which they could carry elastically. This evidence will be published elsewhere[7].

Angular Distribution of Submarine Daylight in Deep Water

In an important paper of 1945, H. H. Poole[1] considers the assumption, suggested in fact by experiments, that at a certain depth in the sea an equilibrium is reached below which the angular distribution of the luminance is constant and independent of the surface-lighting, and the decrease of luminance is an exponential function of the depth characterized by a coefficient of extinction less than (or equal to) the coefficient of total absorption in sea water for a parallel beam. I have recently studied again the problem of the penetration of light in the sea[2], starting from the 'equation of transfer' of the radiation in a scattering medium, and I have found by this theoretical method the existence of an equilibrium condition; the results obtained by an approximate solution of the equation of transfer, in the deep layers, are in good agreement with those given by the direct method of Poole at equilibrium.

Poole's computations used the assumption of isotropic scattering for sea water; this assumption leads to results of simple mathematical form, but unfortunately it is disproved by the reality, as is seen both from the conclusion of Poole and the direct measurements[3]. I have compared these values with those obtained by my method, starting from the assumption of a scattering function with a forward maximum, which corresponds approximately to the actual scattering due to large transparent particles. Adopting the notation of Poole, c is the coefficient of total absorption (true absorption and scattering) for water, sc the coefficient of absorption due to scattering (both for a parallel beam), and kc the coefficient of vertical extinction for radiation at equilibrium in the sea; for the chosen scattering function, the coefficient of scattering in a direction at an angle θ with the direction of incidence is $\frac{sc}{4\pi}[1 + 1\cdot73\,P_1(\cos\theta) + P_2(\cos\theta)]$, where P_n is the Legendre polynomial of order n. If U is the illumination measured by a plane photometer facing downwards, V the illumination measured by a plane photometer facing upwards, and H the illumination measured by a cylindrical photometer with its axis vertical, Figs. 1 and 2 show the variation of k and of the ratios U/V and H/V with s. The curves in full lines are reprinted from Poole's paper and correspond to the isotropic scattering; the dotted curves are deduced from my computations for the scattering function given above.

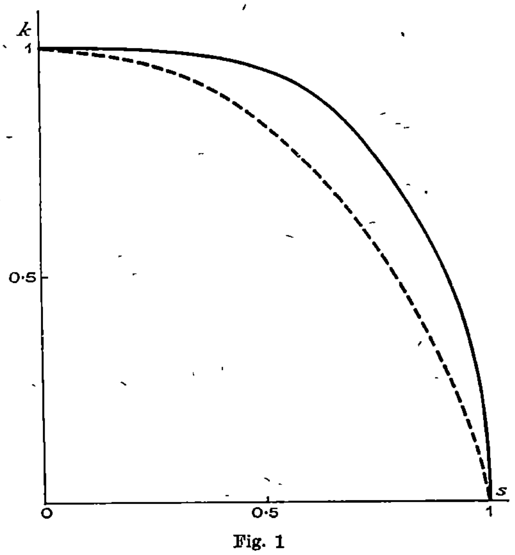

Fig. 1

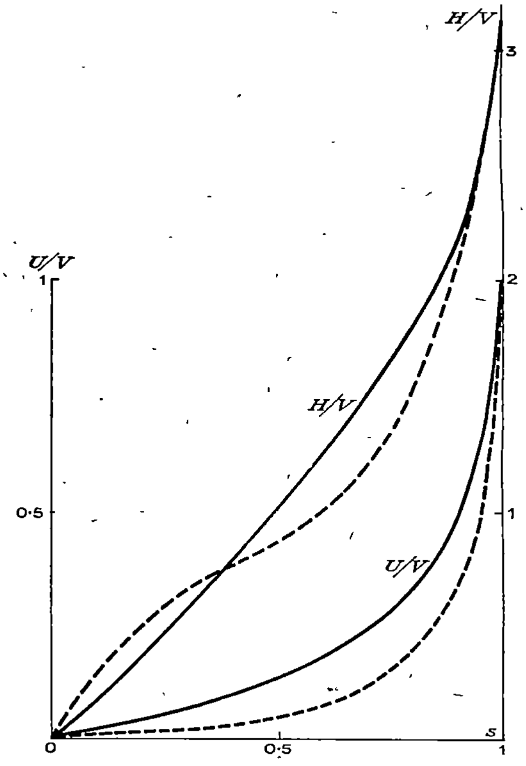

Fig. 2

In his paper, Poole gives some experimental measurements[4] of U/V, and H/V, from which he deduces, by means of curves, two values of s, respectively called s and s'. These results are given in Table 1, together with values of s and s' deduced from my curves; the latter figures are in much better agreement among themselves. So it seems, as was foreseen by Poole, that a scattering function

Table 1

Measurements	Isotropic scattering		Scattering with forward maximum	
	s	s'	s	s'
C_1	0·275		0·53	
C_5	0·189	0·42	0·44	0·47
C_4	0·176	0·40	0·42	0·43
C_3	0·169	0·37	0·40	0·37
C_6	0·167	0·40	0·40	0·44
C_7	0·123	0·40	0·35	0·43

with a large forward maximum corresponds much better to reality than an isotropic scattering.

New Zealand Coals

IN the past twenty years many hundreds of ultimate analyses and many thousands of proximate analyses of New Zealand coals have been made in accordance with British Standard Specifications at the Coal Section of the New Zealand Dominion Laboratory. A preliminary study of these analyses shows that New Zealand coals, varying in rank from peat to semi-anthracite (the anthracites are contact-metamorphosed lignites), almost all belong to a restricted range of coal type different from that of British and North American coals of Carboniferous age.

New Zealand's principal coal seams are of early Senonian to early Oligocene age, but a few Miocene coals are also worked and thin seams occur in younger beds, even as young as early Pleistocene. The rank of the coals, however, appears to be a function neither of age nor of intensity of deformation, but rather of depth of burial.

The seams are usually particularly low in ash, frequently with less than 2 per cent. Coals with high or moderate sulphur contents are widely distributed, the sulphur content bearing a close relation to the stratigraphic distance from marine beds (cf. Wellman[1]). Fig. 1 is a graph, in which the percentage of carbon is plotted against the percentage of hydrogen, for coals with not more than 0·6 per cent sulphur and 7·0 per cent ash, and shows also the 'coal band' for New Zealand coals, extended tentatively to peats. Some of the low-rank coals (in particular some of those with 65–70 per cent carbon) contain abundant resin, with consequent high hydrogen contents, so that some analyses fall above the band. Adjustment of analyses of high- and medium-sulphur coal to a sulphur-free basis cannot be made by the commonly used Parr formula, as the sulphur is almost exclusively organic. Accordingly, these coals are not shown on Fig. 1; but preliminary examination of the analyses shows that most fall within the coal band based on low-sulphur coals.

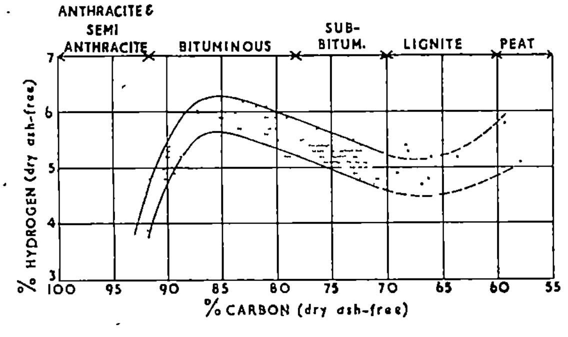

Fig. 1. The New Zealand coal band; coals with not more than 0·6 per cent sulphur and 7 per cent ash

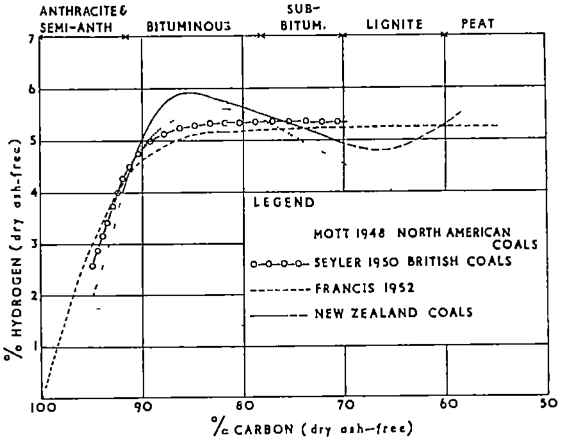

Fig. 2. Mean lines for coal bands of various authors

In Fig. 2 the mean line for the New Zealand coal band is compared with the mean lines adopted by Mott[2] for North American coals, Seyler[3] for British 'bright' coals, and Francis[4] for 'mean ulmins'. These lines trace the metamorphic development of coals of particular types from peat to anthracite. Mott found that those British coals with high durain contents require a subsidiary band of slightly lower hydrogen content than his band for North American coals, but that the difference diminishes with increasing rank; he thus acknowledged that coals of different types would fall in different bands. Likewise, Francis showed different theoretical development curves for perhydrous ulmins and sub-hydrous ulmins.

The scarcity or lack of Carboniferous coals of sub-bituminous, lignite and peat ranks made it necessary for Seyler to extend his coal band from bituminous to lower ranks on the assumption that the mean hydrogen percentage is nearly constant. Francis' theoretical development curve produces a similar result. Mott's coal band, deduced from Carboniferous, Cretaceous and Tertiary coals, shows an increasing hydrogen content from low-rank lignite to bituminous coal; and the New Zealand coal band, based on coals averaging higher hydrogen contents, shows a comparable, though smaller, increase. Thus Seyler's and Francis' theoretical paths of development for coals of low rank do not appear to be borne out in practice.

African Pleistocene Pluvials and European Glaciations

THE most recent book on African prehistory by Mlle. H. Alimen[1] continues to adopt the theory of three pleistocene pluvials and two interpluvials. Her field-work having been mainly in the Sahara, this must be taken as her considered interpretation of phenomena in this part of Africa.

About 1950, however, Leakey in East Africa proposed to divide the Second or Kamasian Pluvial into two[2], thus postulating four pluvials and three interpluvials. This had the advantage of appearing to correspond with the four glaciations and three interglacials of the northern hemisphere. But while the Second Northern Interglacial was longer and warmer than the other two, Mortelmans in the Congo[3] and van Riet Lowe and other workers in South Africa could not find evidence that Leakey's Second African Interpluvial was as severe as the Third, and it still seemed to be a minor oscillation which scarcely justified dividing the Second or Kamasian Pluvial. In 1952 Leakey[4] stressed the faunal break in East Africa during the Second Pluvial, in order not only to justify but also to emphasize the severity of the interpluvial which he had postulated.

Whatever may have happened in the southern hemisphere, it would indeed be surprising if the great ice-sheets in the northern hemisphere did not have a marked effect on climate in low latitudes, at least as far as the equator. To-day, explanations of the pleistocene ice-ages fall into two principal groups: the Simpson group, which postulates changes in radiation emitted by the Sun, and the Milankovich group, which evokes changes in insolation of certain parts of the Earth, especially high latitudes. It is not possible here to examine these theories in detail; suffice it to say that, according to Simpson, temperatures will fluctuate correspondingly in both hemispheres and in all parts of the Earth, whereas according to Milankovich there is no necessary correlation between the hemispheres.

Africa is the only continent straddling the equator where a sufficiently detailed chronology of the pleistocene may be established to test these theories; for human cultures provide probably more sensitive zone-fossils than any biological remains. Very recent researches in West Africa have thrown some light on these problems, and suggest that Alimen's sequence of three and not four pluvials applies not only in the Sahara but also as far as the Guinea coast. Four years ago I began to amass evidence for the Gold Coast[5] of a severe Last Interpluvial corresponding in aridity and in date with the Last Interpluvial of the Congo and South Africa; as in South-West Africa[6], it is not contemporary with but later than the Last Northern Interglacial. There is no clear evidence of an interpluvial within the Second Pluvial, to correspond to the Second Northern Interglacial. So long as this evidence was confined to the coast, though it countered the Simpson type theories, it could be reconciled with the Milankovich type; for greater cold in Antarctica, for which both Milankovich and his successors[7] produce evidence, would intensify the Benguela Current, cool the South Atlantic Ocean, and inhibit rainfall as far as the Gulf of Guinea and over most of the southern part of Africa.

Evidence I have obtained mostly in the last few months from lat. 8–12° N. in the Gold Coast, Togo, Dahomey and especially Nigeria suggests that the Milankovich theory also is untenable. These regions lie north of the Guinea forest and beyond the reach of local marine conditions; their climates should *a priori* be completely northern.

Nearly all the valleys over this area have a similar cross-section. From the gently undulating peneplain there descend very mature slopes. About half-way down, these are rejuvenated with a marked scarp. At the point of rejuvenation there is usually an accumulation of rolled pebbles, and some pebbles are found on the mature slopes, but not as far up as the peneplain. These phenomena have in many cases been dated by artefacts. The rejuvenations belong to the Last Pluvial; the pebble-concentrations mark the valley-bottoms of the Last Interpluvial. Among the pebbles are found numerous rolled pebble-tools, which can scarcely be as late as the Second Pluvial, contemporary with the Chellean and Acheulean cultures. They should belong to the First Interpluvial, and seem to have been dropped on valley-floors about the level where pebbles are observed to start on the mature slopes. There are thus three phases of erosion and two halts, but no indication of an interpluvial during the Second Pluvial.

Secondly, from the distribution of cultures in West and South Africa, it appears that during pluvials man was washed out of the valleys and took refuge on the highlands, whereas in the interpluvials he was forced into the less-parched lowlands. The only highlands in West Africa are the Nigerian plateau and parts of the Togo mountains. The distribution of palæolithic cultures is shown in Table 1.

Table 1

Climatic stage	East African name	Lowland zone: Gold Coast, Togo, Dahomey, Lower Nigeria	Highland zone: Upper Nigeria, ? parts of Togo
First Pluvial	Kageran	—	—
First Interpluvial		Pebble-tools	—
Second Pluvial	Kamasian + Kanjeran	Very little Acheulean	? Chellean, Acheulean abundant
Second Interpluvial		Sangoan	A little Sangoan in Togo only
Third Pluvial	Gamblian	Late Sangoan and probable hiatus	Middle Stone Age
Post-pleistocene dry phase		Very late Middle Stone Age	—

There is no indication of a break during the Second Pluvial or of occupation of the lowland zone. In South Africa there is a minor break at this point. Late Chellean is rare in the Transvaal and abundant in Natal; but it was not arid enough for wind-blown dust to accumulate as it did in the First and Last Interpluvials and in the post-pleistocene dry phase.

Thus it appears that, perhaps as far as 25° N. (according to Alimen), there is a pleistocene sequence of three and not four pluvials, and the Second Pluvial contains a minor dry phase. This sequence cannot be made to correspond with the European glaciations, so the climatic explanations not only of Simpson but also of Milankovich are untenable. The archæologists must now pass the problem back to the meteorologists, and ask them to reconsider it.

Monday, October 8

Institution of Post Office Electrical Engineers (at the stitution of Electrical Engineers, Savoy Place, Victoria Embanknt, London, W.C.2), at 5 p.m.—President's Address—"Fifty Years Telecommunications" (Jubilee Meeting).

British Ornithologists' Union (in the Lecture Hall, British iseum (Natural History), Cromwell Road, London, S.W.7), at 15 p.m.—Presidential Report on the Plans for the Centenary of e Union, to be followed by a General Discussion. 6.0 p.m.—Annual ientific Meeting.

British Society for the History of Science, Philosophy of ience Group (in the Joint Staff Common Room, University College, wer Street, London, W.C.1), at 5.30 p.m.—Dr. G. J. Whitrow: ome Reflections on the Philosophy of Science of Sir Edmund hittaker". (Chairman's Address.)

Society of Chemical Industry, Plastics and Polymer Group t 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. E. B. iomas and Dr. D. Finlayson: "Production and Properties of Cellulose iacetate".

Tuesday, October 9

Society of Chemical Industry, Agriculture Group (at the yal College of Science, South Kensington, London, S.W.7), at .45 a.m.—Meeting on "Polyphenols in Soils and Plants".

University College, London (in the Anatomy Theatre, Gower reet, London, W.C.1), at 1.15 p.m.—Prof. E. G. Turner: "The ead Sea Scrolls and the Hellenistic World".*

Zoological Society of London (at the Zoological Gardens, Regent's rk, London, N.W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Measurement and ontrol Section (at Savoy Place, London, W.C.2), at 5.30 p.m.— . Denis Taylor: "The Measurement of Radioactivity" (Chairman's ldress).

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), 7 p.m.—Mr. A. Stepan: "The Pressure Jet Helicopter".

Wednesday, October 10

Physical Society, Colour Group (in the Lecture Theatre of the ghting Service Bureau, 2 Savoy Hill, London, W.C.2), at 3.30 p.m. Dr. B. H. Crawford: "Lippmann Photography and Interference lters"; Dr. S. Hesselgren (Sweden): "A Colour Classification stem based upon Phenomenological Experiments".

Society of Chemical Industry, Food Group (at 14 Belgrave uare, London, S.W.1), at 6.45 p.m.—Mr. D. M. Ireland: "The iromatographic Determination of Sugar and Oligosaccharides in arch Hydrolysates"; Miss Ruth Bennett and Dr. J. B. M. Coppock: 'he Natural Ageing of Flour".

Royal Institute of Chemistry, London Section (joint meeting th the Isleworth Grammar School Scientific Society, at the eworth Grammar School, Ridgeway Road, Isleworth), at 7 p.m.— . A. E. Werner: "The Scientific Examination of Paintings".

Royal Society of Tropical Medicine and Hygiene (at Manson ouse, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. H. A. id: "Sea Snake Research".

Thursday, October 11

University College, London (in the Anatomy Theatre, Gower eet, London, W.C.1), at 1.15 p.m.—Dr. P. A. Sweet: "The Births d Deaths of the Stars".*

Institution of Naval Architects (in the Weir Lecture Hall, Upper Belgrave Street, London, S.W.1), at 4.45 p.m.—Dr. J. F. lan: "Yacht Testing".

Friday, October 12

Iron and Steel Institute (by arrangement with the British on and Steel Research Association, at 4 Grosvenor Gardens, ndon, S.W.1), at 10 a.m.—"Corrosion" Meeting.

British Mycological Society (in the Large Physics Lecture eatre, Birkbeck College, Malet Street, London, W.C.1), at 11 a.m.— eting on "Mycology and Forestry".

Biochemical Society (at the National Institute for Medical search, Mill Hill, London, N.W.7), at 2 p.m.—Scientific Papers.

North East Coast Institution of Engineers and Shipbuilders the Lecture Theatre of the Mining Institute, Newcastle-uponne), at 6.15 p.m.—Opening General Meeting. Presidential Address Mr. R. C. Thompson.

Royal Institute of Chemistry, London Section (at the Richnd and East Sheen County Grammar School, Park Avenue, East een, London, S.W.14), at 7.30 p.m.—Dr. Norman Booth, Dr. ancis Aylward, Mr. T. McLachlan and Miss Mamie Olliver: "Careers Chemistry".

South Place Ethical Society (at Conway Hall, Red Lion Square, ndon, W.C.1), at 7.30 p.m.—Mr. Fred Hoyle: "The Time Scale the Universe" (47th Conway Memorial Lecture).

Friday, October 12—Saturday, October 13

Faraday Society, Colloid and Biophysics Committee (at the Manson Hall, Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1)—Informal Discussion on "Nucleic Acids and Nucleo-Proteins: Structure and Function".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade B (graduate, with research or industrial experience), in Chemistry—The Principal, Derby and District College of Technology, Normanton Road, Derby (October 13).

Assistant Lecturer in Mathematics—The Registrar, University College of North Staffordshire, Keele (October 15).

Lecturer or Assistant Lecturer in Pure Mathematics—The Secretary, The University, Exeter (October 15).

Senior Lecturer or Lecturer in Extractive Metallurgy, School of Mines and Industries, Adelaide, South Australia—The Agent-General and Trade Commissioner, South Australia House, Marble Arch, London, W.1 (October 18).

Research Chemist (with a first- or second-class honours university degree (or equivalent) in chemistry or biochemistry and satisfactory postgraduate experience in physical or organic chemistry, or biochemistry) in the Department of Agriculture's Peatland Experimental Station at Glenamoy, Co. Mayo—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (October 19).

Assistant Lecturer (with special interests in the field of historical geography) in Geography—The Registrar, University College, Singleton Park, Swansea (October 20).

Soil Surveyors with the New South Wales Department of Agriculture, for duties which will include the carrying out of soil surveys in any part of N.S.W., the preparation of data and draft maps from surveys, laboratory work, etc.—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (October 22).

Lecturer in Mathematics; and Assistants in Mathematics—The Secretary of University Court, The University, Glasgow (October 31).

Lecturer in Physics at Fourah Bay College, Sierra Leone—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (October 31).

Senior Lecturer or Lecturer (preferably with experience and research interests either in the application of modern inorganic and physico-chemical principles to analytical chemistry, or in the field of geochemistry) in Analytical Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Professor, Senior Lecturers (2) and a Lecturer, in the Department of Chemistry and Chemical Technology, University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 8).

Lecturer in Physics—The Registrar (Room 9, O.R.B.), The University, Reading (November 12).

Chair of Chemistry in Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 13).

Lecturer in the Department of Botany at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, November 15).

Lecturer or Assistant Lecturer in Physics at Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30)

Assistant (Grade B) in the Department of Mathematics, Bradford Technical College—The Director of Education, Town Hall, Bradford.

Assistant, Grade B (preferably with an honours degree and teaching, research or industrial experience), in Physics—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

Assistant Lecturer in Biology—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.C.1.

Assistant Lecturer (with an honours degree in agricultural botany or botany, and a special interest in plant pathology) in Agricultural Botany—The Bursar, Royal Agricultural College, Cirencester.

Assistant (preferably with some botanical training) for supervising plots of wheat—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Chemist (honours graduate with at least three years research experience) for studies of the properties of coal extracts and of the halogenation of coals and allied materials—The Assistant Secretary, British Coal Utilization Research Association, Randalls Road, Leatherhead, Surrey, quoting Ref. C.64.

Electronics Technician, to take charge of a new electronics workshop for constructing and maintaining laboratory equipment—The Registrar, The University, Nottingham.

Librarian—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

Physicist (with an honours degree in physics or equivalent qualification) with the Radiological Protection Service (M.R.C. and Ministry of Health), at Sutton, to carry out special investigations into problems associated with radiological protection, for example, the extent of the hazard involved in the present-day use of ionizing radiations—The Director, Radiological Protection Service, Downs Nursery Hospital, Sutton, Surrey.

Physicists or Physical Chemists (with a good honours degree in physics or chemistry, and preferably some research experience) for both fundamental and technological research projects—The Appointments Officer, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22.

POLYMER CHEMIST, to work on the physical properties of irradiated polymers—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 639/34.

SENIOR LECTURER IN PHYSIOLOGY AND PHARMACOLOGY at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

SENIOR SCIENTIFIC OFFICER/SCIENTIFIC OFFICER (with a first- or second-class honours degree in physical chemistry or physics, and experience in infra-red spectroscopy and a good knowledge of the interpretation of spectra) to join a team engaged on research in the field of spectroscopy—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 1207/34.

LECTURES AND COURSES

NORTHERN POLYTECHNIC

HOLLOWAY, N.7

COURSES LEADING TO THE B SC. SPECIAL DEGREE IN CHEMISTRY AND IN PHYSICS FOR STUDENTS ENGAGED IN INDUSTRY.

Students attend these courses, of duration four years, by arrangement with their employers. Two terms of each year are spent in full-time study and the third term in part-time study. Those suitably qualified may proceed as Internal Students of the University of London.

Any students wishing to enrol for the 1956-57 session should apply immediately to the Secretary, Northern Polytechnic, Holloway Road, London, N.7, from whom further information can be obtained.

OFFICIAL APPOINTMENTS

NORTH LINDSEY TECHNICAL COLLEGE

KINGSWAY, SCUNTHORPE, LINCS
Principal: F. C. Jones, B Sc (Eng.), A.M.I.Mech.E., A.M I E.E.

Applications are invited for the following appointments: (a) Fitter-Turner for general machining and fitting in connection with the manufacture and maintenance of a wide range of apparatus and equipment. The appointment offers interesting work with good conditions to the right type of applicant A good apprenticeship and possession of a City and Guilds Intermediate Certificate in Machine Shop Engineering would be useful recommendations. Salary £9 14s. 4d. per 44 hour week. Duties to commence as early as possible. (b) Laboratory Steward for general laboratory duties in the Engineering and Building Departments Previous experience in the preparation and maintenance of this type of apparatus and equipment is essential. Possession of a national certificate or City and Guilds Certificate in an appropriate subject would be a recommendation. Salary and conditions in accordance with Miscellaneous, Div. III of N J.C. Scale, i.e., £445 rising to £510 per annum, by three increments of £15 and one of £20. Duties to commence as early as possible.

Apply by letter to the Principal at the above address as early as possible, giving full details of age, experience, and qualifications, copies of two recent testimonials, and the names of two persons for confidential reference.

UNIVERSITY OF MELBOURNE

AUSTRALIA

Applications are invited for a position of Senior Lecturer or Lecturer in Analytical Chemistry. The appointee will be expected to take up duty on or about March 1, 1957. The Lecturer will be responsible for the organization of the laboratory work and lectures in analytical chemistry in the second and third years of the degree course, and will be expected to undertake research. Preference will be given to applicants with experience and research interests either in the application of modern inorganic and physico-chemical principles to analytical chemistry, or in the field of geochemistry. The salary ranges are: Senior Lecturer, £A.1,850 to £A.2,150 per annum; Lecturer, £A.1,300 to £A 1,800 per annum. Superannuation similar to F.S.S.U. will be provided.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Australia and London, is October 31, 1956.

STOBHILL GENERAL HOSPITAL

GLASGOW, N 1

Applications are invited from suitably qualified candidates for the post of Biochemist, Senior Grade, at the above hospital. The applicant appointed will work under the direction of a consultant clinical Biochemist (Medical), from whom further information may be obtained. Salary, etc., in accordance with Whitley Council Scale (rising to maximum of £1,230 per annum).

Applications, together with the names and addresses of two referees, should be sent to Medical Superintendent not later than three weeks after the appearance of this notice

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION
APPOINTMENT NO. 270/143 OF SOILS PHYSICIST
DIVISION OF SOILS

Applications are invited for appointment to a position of Soils Physicist at the Division's headquarters in Adelaide. This position relates initially to research on the movement and measurement of water in soils. The present investigation is into the use and application of a neutron scattering method which is being developed. The appointee will have considerable freedom in developing lines of research within the general field of soil physics. Qualifications . University honours degree in science (with physics as a major subject) together with evidence of research experience, preferably in the field of soil physics. Salary : Dependent on qualifications and experience, commencing salary will be within the range of Senior Research Officer (£A.2,022 to £A.2,297) or Research Officer (£A.1,287 to £A 1,912). Note: The above salaries apply to a male appointee. Salary for a female appointee will be £160 per annum, less than corresponding male salary The appointment will be conditional on a satisfactory medical examination and the successful applicant will be required to contribute to, and eligible to receive benefits from either the Commonwealth Superannuation Fund or the Commonwealth Provident Account. Fares to Australia (including those of wife and family) will be paid

Applications, referring to appointment number 270/143, and stating full name, place, date and year of birth, marital state, nationality, present employment, particulars of qualifications and experience, and of war service, if any, accompanied by copies of not more than four testimonials and the names and addresses of at least two persons willing to act as referees if required, should reach the undersigned (from whom further particulars may be obtained) not later than November 3, 1956

A. SHAVITSKY,
Chief Scientific Liaison Officer.
Australian Scientific Liaison Office,
Africa House,
Kingsway, London, W.C.2.

COMMONWEALTH of AUSTRALIA

DEPARTMENT OF SUPPLY
DEFENCE STANDARDS LABORATORIES
MARIBYRNONG—VICTORIA

Applications are invited for a position of Scientific Officer, Grade 1, at the above establishment Salary : £A.1,287 to £A.1,602 per annum. Duties: Undertake research on explosives; the successful applicant will be expected to join a section working on the fundamentals of initiation and detonation, the results to be applied to interesting new developments for the services. Qualifications: University degree of high standard with chemistry a major subject or equivalent qualifications, preferably with some research experience. Whilst the position is a temporary one, the tenure of employment is not limited. However, the successful applicant may choose to enter into an agreement for a three to five year contract of employment in Australia In this case, the Commonwealth will bear return fares, together with the cost of removing each way the appointee's furniture and effects up to a maximum cost of £A.500, £A.250 each way. Under specified conditions, first-class boat fare (if first-class berth available) for the appointee and dependants (wife and dependent children) will be paid by the Commonwealth.

Application forms obtainable from Senior Representative (AP.66), Department of Supply, Australia House, Strand, London, W C.2, with whom applications should be lodged by November 1, 1956

PRINCIPAL/SENIOR SCIENTIFIC OFFICER required by the Atomic Weapons Research Establishment, Aldermaston, Berks, to lead a team concerned with chemical process development and plant design studies. This post offers experience of novel problems in the atomic energy field. Applicants should hold a first- or second-class honours degree in chemical engineering or chemistry and/or A.M.I.Chem.E. They should be qualified chemical engineers with some research and development experience, or, alternatively qualified chemists with experience in chemical engineering. Salary: Principal Scientific Officer, £1,390 to £1,980 per annum; Senior Scientific Officer, £1,155 to £1,355 per annum. Contributory superannuation scheme. A house, or assistance towards legel expenses in house purchase will be available for married officers living beyond daily travelling distance.—Requests for application forms by postcard to the Senior Recruitment Officer at the above address. Please quote reference A.1169/34.

UNITED KINGDOM ATOM ENERGY AUTHORITY

invites applications for posts at its
wich Outstation for work in the field

ANALYTICAL CHEMISTRY

associated with the whole work of th
search Group (at Harwell and elsewhe
developments in atomic energy.

Salary: The posts will be graded a
ing to age, qualifications and experien
either:

Scientific Officer: £664 9s. to £1,1
per annum (minimum qualifications: a
or second-class honours degree, or eq
ent) or

Assistant Experimental Officer · £4
age 18) to £879 16s. per annum. (Min
qualifications: G.C.E. Advanced le
two science subjects, or equivalent).

There are excellent facilities availab
tackling the new and interesting pro
arising, including modern equipmen
emission and absorption spectros
polarography, radiochemistry, X-ray
escence, vacuum fusion, etc.

Send postcard for further details a
application form, which must be ret
by October 16, 1956, to Establisl
Officer, A.E R.E , Harwell, Didcot,
quoting reference 641/34.

Information Theory

Proceedings of the Third London Symposium, 1955

Edited by Dr. COLIN CHERRY, Reader in Electrical Engineering, Imperial College of Science and Technology, University of London.

The full text of the papers read, and the ensuing discussions, at the Third London Symposium, 1955. The papers are divided into five main groups: Fundamentals; Coding, Taxonomy, etc.; Language Analysis and Mechanical Translation; Meaning and Human Senses; Behaviour and Mechanism.

Price 70*s.*

Chemistry and Mode of Action of Plant Growth Substances

Edited by Professor R. L. WAIN, M.Sc., D.Sc., F.R.I.C., and F. WIGHTMAN, B.Sc., Wye College, University of London.

Contains the papers read, and the ensuing discussions, at a symposium held at Wye College, University of London, in 1955. The papers read are classed under the following headings: Natural Auxins; Chemical Structure and Biological Activity; Metabolism and Mode of Action; Applications of Kinetics to Auxin-induced Growth.

Price 55*s.*

Transport and Accumulation in Biological Systems

By E. J. HARRIS, D.I.C., D.Sc., Department of Biophysics, University of London.

This book is a critical appraisal of the more important information which has been published recently on the subjects of cellular inorganic chemistry and the kinetics of movement of inorganic and simple organic substances between cells and their surroundings.

Price 47*s.* 6*d.*

INDUSTRY AND TECHNOLOGICAL TRAINING

IN recent years the role of the research associations in Britain in providing the industries they serve with trained scientific and technological staff has been increasingly recognized and was indeed the subject of a private conference in London in November 1953, which was attended by members of the Advisory Council for Scientific and Industrial Research, the chairmen and directors of the research associations and some representatives of the universities. Although the discussions at this conference covered a wide field, they were concerned more with the relations between the universities and technical colleges and the research associations than with those between the latter and industry. The contribution of the research associations to technical, and more especially to technological, education has since received much attention, and may well become even more important with the increasing stress laid upon the 'sandwich system' in the White Paper on Technical Education and elsewhere.

This contribution is essentially one made from within industry. It could assist, for example, the university-trained scientist to acquire technical knowledge or technological skill which he would find difficult to obtain either in the smaller firm or even in the best-equipped college of technology. It needs to be remembered in discussing the expansion of technological or technical education that there are limits to the acquisition of such knowledge before entrance to industry, limits set by the nature of the technical skill or knowledge concerned and by economic factors, quite as much as by the curriculum of a college or university. The point has been well made at some of the conferences with the universities arranged by the Federation of British Industries, but without its full implications being brought out as clearly as is done by Prof. Hyman Levy in the challenging article "The Chaos in Scientific Recruitment" which he contributed to the *Rationalist Annual* of 1956. Levy argues that if we are to meet the demands for trained man-power which a modern industrial community makes, we must solve the problem of providing for the transition to the scientific or theoretical side of those whose scientific ability or desires only develop after practical experience of industrial or commercial life. To do this we must have a clear understanding of the outlook and experience of the young factory worker, and Levy suggests that an extension of the scope, at once educational, technical and scientific, of the considerable scientific establishments or research laboratories which most of the larger industries already possess, would provide the basis for what is needed.

Prof. Levy is undoubtedly right in insisting that industry must accept a larger share of the responsibility for initiating and developing the institutions that are required to supply the trained man-power that a modern technological community needs; but while he does not attempt to outline the details of a definite scheme, the extent to which it can and should be given within industry requires rather more consideration than it has yet received. To some extent the attention given to automation in recent months has helped here, for it has been obvious that some of the techniques involved can only be acquired within industry. This has also been very noticeable in the development of nuclear energy. In spite of the great activity in nuclear physics at the universities, the Atomic Energy Authority has had to assume, through its Reactor School at Harwell and its Isotope School, a major share of responsibility for providing industry with the staff it requires if it is to take its full part in exploiting the commercial applications of nuclear energy. In its second annual report, the Authority stated that it was considering what expansion should be made in its training facilities, particularly for scientific and technical staff, in the light of the White Paper on Technical Education.

This aspect of technical education—that of the training given within industry—was rather overlooked in the two debates in the House of Commons on July 25 and August 2. In the former, indeed, Mr. F. Peart emphasized that technical education cannot be divorced from the general educational system, and Sir David Eccles stressed the importance of collaboration between the technical colleges and the modern secondary schools. It was suggested by Mr. J. Hall that there might be a tendency to overlook the part of the grammar schools in the production of first-class scientists and that the Ministry might be differentiating too rigidly between technical and scientific training on one hand and grammar school training on the other; but apart from an incidental reference by Mr. Hubert Ashton, the co-operation of industry was scarcely mentioned, even by Mr. A. Skeffington in opening the adjournment debate on technical education on August 2 and referring to the sandwich courses. Mr. Dennis Vosper, Parliamentary Secretary to the Ministry of Education, who replied in both debates, agreed that the means of financing sandwich courses is at the moment difficult and said that the Minister would be issuing advice about the financing of students in such courses. He gave figures showing increases in the numbers of students taking sandwich courses, and said that the signs for the coming year are of further increases. The fall in numbers attending full-time degree courses was largely due to the decrease in further educational training schemes and the general decrease in pressure on the universities and technical courses in recent years. He said he has no evidence that the provision of technical colleges and the supply of teachers and of students are not, in fact, keeping pace one with another. The number of technical State scholarships has been increased to 150 and the Minister is prepared to increase this figure if the number of students is forthcoming.

In neither debate was convincing evidence adduced that the increase in fees for non-vocational courses in further education is unjustified or likely to be detrimental, but the discussion would have been a good deal more realistic in the light of considerations advanced by Mr. J. Wellens in his recent book "Education and Training in Industry"*. Mr. Wellens is concerned with current practice in what he describes as industrial training—the training which industry gives to its new entrants at the level of craft or staff apprentices, to its operatives, or to those destined to be supervisors, foremen or managers. He reviews such practice with three aims. First, to set down a system which could reasonably and currently be regarded as basic; second, to propound the doctrine of integrated training; and third, to indicate the necessity of a framework of organization which will permit and promote the efficiency of training.

Mr. Wellens writes from the point of view of a 'training officer' in industry, with responsibility for seeing that an adequate supply of correctly equipped employees is available at all times and at all levels in the organization. He is aware, too, that this should be done so as to provide a balanced, contented and efficient labour force, one with an immediately available pool from which promotions can readily and adequately be made, yet not so large that frustration or wastage easily arises. He is aware, too, of the implications of automation, with its growing demand for more highly trained technicians and for technologists of a very high order, while that for the manual worker decreases.

If this is to be achieved, the training officer must do much more than operate a routine training system. He must see industry as a way of life, not merely as a means of earning a livelihood. He must be able himself to make some creative contribution, and however suited the educational system of the country may be for providing the quality of recruits required, he should be capable of formulating precisely the further contribution which industry must supply, and securing from the management the conditions in which that training can most effectively be given.

Mr. Wellens begins by formulating the general principles which should normally govern any training scheme. Its purpose should be clearly defined, and also the relation between the training department and the personnel department. It should be recognized that something more is needed than the inauguration of facilities for training, and that training is a continuous process but nevertheless not the prime concern of industry; and while the purpose of training should not be narrow, it must be judged according to the way in which it furthers the primary purpose of industry.

Three further principles are particularly important, not merely because their neglect often brings training into disrepute, but equally because of their relevance elsewhere in the field of technical education. Training, Mr. Wellens points out, does not give men an automatic right for preference in promotion. Three factors are involved: technical knowledge, practica experience and personality. All three are in some measure indispensable. Again, he insists on the importance of consultation. Training officers do not operate in a vacuum. Further, training is concerned with future rather than present needs, and a training officer must have vision and imagination and be wel abreast of modern practices and trends.

All these three principles are important in planning the expansion of technical and of technological education. The last is one of the essential reasons why at the higher levels some training must always be given within industry rather than in a college of technology, however well equipped it may be. It is not merely the cost of equipment that makes it difficult for the latter to be thoroughly up to date All three principles are supported, as is Mr. Wellens's insistence both on the importance of regarding all training as a unity and of an appropriate organization within which training can be effected, by the recent report on management succession from the Acton Society Trust and by Lord Heyworth's recent observations on training for management, when he also insisted on the importance of co-operation between industry and the universities and that an essential part of such training must be given within industry and indeed on the job itself.

That is indeed recognized by Mr. Wellens, for although much of his book is concerned with the training of apprentices and operatives and stresses the need for fresh thinking about the appropriateness of existing practice to modern conditions—on the part of the trade unions as well as of management and educational institutions—in his chapters on university study and scholarship schemes and on management training he discusses just those problems of the university graduate in industry and the provision of a steady supply of managers of high ability with which Lord Heyworth and the Acton Society Trust were concerned. The principles which Mr. Wellens advocates could go far to assist the effective utilization of the university graduate in industry and the elimination of that serious wastage on which the Acton Society Trust laid such stress in its report. Wastage will only be eliminated if there is a definite plan within a firm for developing managerial talent as well as discovering it; and while it is clear that the training officer can play a big part here, Mr. Wellens does not overstress that part. He emphasizes rather that the solution is to be found in terms of organization rather than in terms o educational technique.

There are two points to be noted here. First, there is room for further inquiry into the personality aspects of management rather than the academic aspects. The Acton Society Trust has by no means exhausted the subject, and there is room for further studies by the Trust as well as by the British Institute of Management. Second, while Mr. Wellens agrees that an essential part of training for management must be given on the job, he is careful to point out that such training involves forethought and deliberate effort on the part of the principal concerned, as wel as careful control and organization and guidance. It must be planned training just as much as if it were given in an educational establishment.

---

* Education and Training in Industry. By John Wellens. Pp. x + 142. (Manchester: Columbine Press, 1955.) 17s. 6d. net.

Mr. Wellens does not attempt to forecast the fundamental form which training for management in Britain may assume when, and if, it becomes stabilized. He displays the broad field over which cooperation is required between industry, the trade unions, the universities and the colleges of technology. He indicates the need for fresh thought as well as for definite organization, and his book is a stimulating contribution in that direction which should not be neglected either by those responsible for shaping the expansion of technical or technological education, or by those concerned with the organization of training within industry itself.

While, however, Mr. Wellens recognizes the main factors involved and the ways in which a wide outlook and broad general education could be encouraged at the different levels, on one key problem he scarcely comments, namely, the provision of teachers. This is a vital matter in the development of sandwich courses, in the expansion of technical education and in the organization of training in industry itself along the lines which Mr. Wellens suggests. It could well be true that there are sections of industry where much more could be done by way of co-operation with the universities or the colleges of technology, in the release of staff as part-time lecturers, as well as in the organization of its own training schemes; but it must be remembered none the less that there are limits to what industry as such can do. Training, as Mr. Wellens rightly points out, is a subordinate and not a primary function of industry.

The supply of teachers, especially of science and technology, thus remains a key problem in the development of training within industry, as it is also in the expansion of technical and technological education. The co-operation of industry may help to alleviate the situation at some points but scarcely to remove the existing shortage. Moreover, very careful thinking and organization will be required if the scientific establishments of industry—and especially its research establishments—are to undertake the educational responsibilities which Prof. Levy suggests. Admittedly, the teacher derives inspiration from close association with the advancement of knowledge; but it is by no means certain that the way in which teaching and research are at present associated is the most effective for teaching or for research. It may well hinder, as Dr. R. Coulborn pointed out twenty years ago, the development of the valuable personal relation between teacher and student, turn the energy of the undergraduate into work for which he is unsuited and which he is unlikely ever to use, as well as waste the time of the teacher and obstruct his own original thinking or research.

It is rightly being urged that the technical colleges and colleges of technology in Britain should be staffed and equipped so as to permit more original research in technical fields being undertaken, and it is true that they could often help industry considerably in this way. Both here and in the research associations, however, there is need for further inquiry and thought, not merely as to the type of problems which could be investigated in this way, but also as to the exact relation between research and teaching. Here, and in the universities also, this question needs to be re-examined in the light of the principle that scarce material must be used with forethought and economy; and it could well be that further critical and unprejudiced inquiry could point to ways in which more effective use could be made of the limited numbers of teachers of science and technology in Britain, as well as in turning larger numbers of promising students into such fields and training them more efficiently and speedily.

NAPHTHALENESULPHONIC ACIDS AND STEROIDS

Elsevier's Encyclopaedia of Organic Chemistry
Edited by Dr. F. Radt. Series 3: Carboisocyclic Condensed Compounds. Vol. 12*B*: Naphthalene. *A*. Compounds Containing One Naphthalene Nucleus. Sulphonic Acids: SO_3H in Side Chain; One SO_3H in the Nucleus. Pp. 4841–5686. (1955.) £21 10*s*.

Vol. 14, Supplement. Steroids: Substituted Monohydroxyl Compounds; Polyhydroxyl Compounds. Edited by A. Georg, with the assistance of M. Georg-Plant, Dora Stern and J. Meyer. Pp. 1869*s*–2214*s*. (1956.) £9 10*s*.

(Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd.)

THESE two parts in "Elsevier's Encyclopaedia of Organic Chemistry" take their respective volumes a stage nearer completion. In the first the literature is stated to be covered up to 1944 and the literature concerning the structure of compounds up to 1955, while in the second the coverage is up to 1946 with reference to papers on structure and configuration up to 1955. As might be expected, in view of the subjects treated, references to publications of the past decade are more abundant in the second of these parts than in the first.

Naphthalenesulphonic acids and their amino- and hydroxy-derivatives are, to the dyestuffs chemist, among the most important derivatives of naphthalene, and this part of Vol. 12*B* deals with such compounds containing one sulphonic acid group and also with azo dyes related to them. In regard to the latter, it is useful to find references to their numbers in the "Colour Index" and in "Farbenstofftabellen", and it is also to be noted that the lists of references include not only titles of scientific periodicals but also some of the more important patent specifications and such well-known monographs as those of Fierz–David and of Venkataraman. True to the traditions of the "Encyclopaedia", interesting information about biological properties is scattered through the part; thus, there is reference to the plant growth-promoting action of such compounds as the sulphonic acid analogue of 1-naphthylacetic acid; we read that 2-naphthol-6-sulphonic acid is only moderately toxic to body lice; and there is a brief digest of the voluminous literature on the biological properties of congo red. A useful feature is the list of trivial names of naphthalenesulphonic acids and their derivatives. This includes also the compounds with more than one sulphonic acid group, which are not otherwise dealt with in this part. It is valuable to have so much information about the sulphonated naphthalene derivatives arranged in such compact and easily accessible form, even though much of the material is already summarized in monographs and other publications.

The Supplement to Vol. 14, on steroids, "comprises the halogen and nitrogen substituted monohydroxylated compounds with one OH in the ring system, and all polyhydroxylated compounds, having at least one OH in the ring system, with or without halogen or nitrogen substituents". Hence there is included the addition products of sterols with halogens and halogen acids, the nitro-, amino- and azo-derivatives of the sterols, the œstradiols, œstratriols and diols and triols of the androstane, pregnane, cholestane and ergostane series. Configurations are given so far as they are known, and the work will be an invaluable compendium to those interested in steroid chemistry. There are the usual tables of physical constants of the more important groups of compounds, references to physiological properties, usually œstrogenic or androgenic activity, and the part is liberally supplied with editorial footnotes clearing up points of obscurity or confusion in the original literature.

Both parts reach the standard of excellence of production to which users of "Elsevier's Encyclopaedia" are now well accustomed. J. W. COOK

REACTIVITY OF COLLAGEN

The Chemistry and Reactivity of Collagen

By K. H. Gustavson. Pp. ix+342. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 8 dollars.

DR. K. H. GUSTAVSON was awarded the Grand Gold Medal by the Royal Swedish Academy of Technical Sciences in 1955 for his pioneering contributions, which form the background to the present monograph. A knowledge of the chemistry and reactivity of the fibrous protein collagen is of fundamental interest to workers in the fields of biochemistry, medicine and leather technology. The book gives an able review of widely dispersed information in the light of the modern theories of protein reactions. Special attention is given to reactions which form the basis for the processing of skin prior to tanning and for the making of gelatin.

After a general survey of the chemistry of proteins, including the methods for estimating the terminal groups, a clear picture of the composition of collagen in terms of amino-acids is given, along with a discussion of their sequence. The parts played by X-ray techniques, electron microscopy and birefringence in revealing the architecture of this protein are lucidly discussed, showing the developments which have occurred since 1940 when W. T. Astbury put forward his original model for the configuration of the polypeptide chain.

The amphoteric ionic structure gives rise to many of the properties of the collagens. The charged centres of the protein zwitterion exist in electrostatic balance with each other at the isoelectric point. The methods for the determination of the latter are discussed critically, and it is shown that its location with hide collagen is a function of the alkali pretreatment. Acids and bases disturb this balance, and the reactions which occur are examined in detail because they are of fundamental importance for the understanding of the general reactivity of collagen. The meanings of the various titration curves are clearly explained.

The cohesion of the collagen molecule is, of course, one of its characteristic features. This is due to electrovalent salt links and hydrogen bonds, but the desirability of increasing our very limited knowledge of the distances between the reactive groups is rightly emphasized. The significance of this structural restraint is clearly explained in discussing the Procter–Wilson extension of the Donnan effect in connexion with osmotic swelling. The lyotropic effects of neutral salts, urea, weak acids and phenols are shown to be intimately connected with hydrogen bonding.

The various aspects of the thermal shrinkage of collagen and connective tissues are adequately discussed with reference to the different types of collagen. The shrinkage temperature measures the hydrothermal stability. Tanning agents increase its value due to the formation of cross-linkages. The reactivity of collagen is profoundly influenced by the inactivation of its amino and carboxyl groups, and a comprehensive account of the relevant researches in this field is given. The splitting of proteins into peptones, polypeptides and amino-acids by proteolytic enzymes is vitally important when they are used for nourishment. It is also an important reaction in their decomposition when they undergo putrefaction. The effects of proteinases on native and tanned collagen are therefore discussed. The final chapters deal with the problem of unhairing, the conversion of collagen into gelatin and some physicochemical aspects of its reactions with tanning agents, which includes an account of the contributions of the monolayer technique to the problem of tannage.

The monograph is most interesting to research workers in the field of collagen and will serve as a useful book of reference for many years to come. It covers the literature up to late in 1954, and the views of the various investigators are on the whole well covered. The index is good, but there are a considerable number of typographical errors. Those who are not specialists will, however, find it difficult to read because the descriptions of the experimental methods are very brief and it is assumed that the reader is familiar with the underlying theory.

DONALD BURTON

AMERICAN COLOUR TELEVISION

Color Television Standards

Selected papers and records of the National Television System Committee. Edited by Donald G. Fink. (McGraw-Hill Television Series.) Pp. xii+520. (London: McGraw-Hill Publishing Company, 1955.) 64s.

THIS book is a sequel to "Television Standards and Practice" (1943) by the same author, the latter comprising information produced by the first nine panels of the then recently formed National Television System Committee in the United States. This Committee had been allocated the task of formulating suitable standards for monochrome television transmissions so that the Federal Communications Commission could accept them officially. The first Committee, which formulated the monochrome standards, issued a set of volumes comprising 2,000 pages, while the second, the findings of which are summarized in the volume under notice, issued a number of volumes totalling 4,100 pages. This work was the result of co-operation between more than thirty organizations comprising the greater part of the American radio and electronics industry. It is perhaps interesting to note that, whereas the formulation of monochrome standards required 2,000 pages, the formulation of colour standards, which of course are based on monochrome, required *in toto* 6,000 pages—three times the number required for monochrome. Does this ratio depend upon the fact that ideal colour television requires the transmission of three times the information needed for monochrome ?

The book is divided into ten chapters and two appendixes. Chapter 1 covers the later history of colour television and includes a useful set of questions and answers and references to appropriate parts of the book. Chapter 2, which the serious reader is recommended to read first, includes a very clear description of the American colour television signal specifications. A considerable proportion of the information contained in this chapter may be found in the *Proceedings of the Institute of Radio Engineers*, 42, No. 1 ; January 1954. Chapter 3 contains an abbreviated description of some subjective tests which have already been described in greater detail (*Proc. Inst. Rad. Eng.*, 30, No. 8 ; August 1952), and a lengthy set of questions and answers which is worth while reading if only to gauge the extent of disagreement which still exists with regard to many fundamental subjective questions relating to human vision.

Chapter 4 (which begins on p. 102 and not on p. 212 as shown in the list of contents) is entitled "The Color Video Signal" and contains a large number of technical monographs of the National Television System Committee, nearly all of which have been published elsewhere (*Proc. Inst. Rad. Eng.*, 30, No. 8, August 1952 ; and 41, No. 7, July 1953). The serious student of colour television will find this chapter of immense value, as it covers most of the theoretical and practical work which led to the formulation of the American colour television signal specifications.

Practically all Chapter 5, "The Color Synchronizing Signal", is taken up by the excellent mathematical study, "Color-Carrier Reference-phase Synchronization Accuracy in N.T.S.C. Color Television", by Richman ; once again, this paper has appeared elsewhere (*Proc. Inst. Rad. Eng.*, 42, No. 1 ; 1954).

Chapters 6, 7 and 8 will interest mainly those responsible for television broadcasting and transmitters, as well as members of committees charged with advising governments and official bodies as regards the choice of a colour television system for their respective countries. Chapter 9 will again interest those connected with television broadcasting, but here work connected with electronic masking is described and this may well be of interest to members of the photographic industry.

Chapter 10 will be a source of constant reference for engineers dealing directly with colour television problems, especially in connexion with standardization and use of appropriate terminology.

Appendix 1 is intended as a description of National Television System Committee colour television in non-technical terms and might well be read by those who have administrative rather than technical duties to perform in connexion with colour television. Appendix 2 contains, in abbreviated form, some of the information to be found in Chapter 2.

This book will be used primarily as a work of reference by engineers directly concerned with colour television. It may also be read by students of the subject, but in this case it is recommended that serious study of the book should be preceded by the reading of a suitable introduction to colour television. The book presents an excellent example of the application of fundamental physical principles to a practical problem and therefore, although principally a book for engineers, it may well find favour among physicists.

The author, Donald G. Fink, was for many years editor of the well-known American journal *Electronics* and is at present a member of the board of directors of the Institute of Radio Engineers in the post of editor. In his capacities as editor of the Proceedings of the first National Television System Committee (1940–41), vice-chairman of the second Committee (1950–52), chairman of Panel 12 (Colour System Analysis), and director of research of the Philco Corporation, he has acquired a very extensive knowledge of both monochrome and colour television, and is undoubtedly well qualified to produce this authorized compendium of the eighteen volumes produced by the second National Television System Committee (1950–53). R. D. A. MAURICE

THE WEST INDIAN FAMILY

The Negro Family in British Guiana

Family Structure and Social Status in the Villages. By Dr. Raymond T. Smith. (International Library of Sociology and Social Reconstruction.) Pp. xvi + 282 + 8 plates. (London : Routledge and Kegan Paul, Ltd. ; New York : Grove Press, Inc., in association with the Institute of Social and Economic Research, University College of the West Indies, Jamaica, 1956.) 28*s.* net.

THE Caribbean region has been neglected by British anthropologists, partly for financial reasons and partly because of a legitimate concentration of interest on the study of non-European societies with a distinctive culture of their own. Interest in the region was awakened largely through the social policy introduced at the end of the Second World War, and public interest in the structure of the family is largely concerned with its relevance for such policy. Census figures have revealed that, in the poorer strata of the Negro population, a high proportion of children are born out of wedlock and a considerable number of conjugal unions are not legally sanctioned. They have been held to reinforce the middle-class myth of Negro immorality and promiscuity, and historical explanations of these alleged characteristics have been sought both in the values and modes of behaviour which became customary under slavery and in those which the Negroes brought with them from Africa.

Dr. R. T. Smith begins by challenging the initial assumption. From his intensive study of three Guianese villages, he concludes that there is no significant difference, in terms of the obligations recognized between the partners and towards their children, between marriage and the extra-legal domestic unions which he calls 'common-law marriage'. 'Common-law marriage' is simply the standard pattern for the lower class. A 'common-law wife' has herself no legal claims on her consort ; but he is legally liable for the support of his children as a husband is. Though the point would not affect his main argument, it might be interesting to know how far maintenance orders are in fact sought and enforced; Dr. Smith writes almost as if he was asserting that the courts provide a watertight system.

Of course marriage, as the middle- and upper-class pattern, carries with it associations of higher status; but for that very reason it is not sought after by everyone. Persons who are seeking to raise their status will marry, others will not do so although they could well afford the expense of the celebration and the generally higher standard of living popularly associated with a married household.

In addition to producing the first fully documented study of the Negro family in the Caribbean, Dr. Smith has made some valuable contributions to general theory. He is the first explicitly to tackle the problem which must constantly arise now that anthropologists are transferring their attention from social units which can be treated as total systems to localities the boundaries of which are geographical rather than social. The Guianese village is wholly dependent politically and economically on the wider system of which it forms a part, and, what is more significant, the characteristic features of household and family are explicable only in terms of the place of the village population in the total structure. Thus the problem itself dictates how far the investigator must go outside the geographical boundaries of the sub-system selected for study.

Dr. Smith decisively rejects explanations in terms of the cultural background—that is, in effect, of history—though he recognizes that the synchronic study must cover the period of time necessary for household or family to pass through its full three-generation cycle of development. Space does not permit discussion of all the original ideas in this stimulating book.

L. P. MAIR

PREVENTIVE PSYCHIATRY

Emotional Problems of Early Childhood

Edited by Prof. Gerald Caplan. Pp. xiv+544. (London: Tavistock Publications, Ltd., 1955.) 42s. net.

THIS book is the result of a symposium under the auspices of the International Institute of Child Psychiatry. Its theme is "The Child under Six", and its main headings are: psychosis in early childhood; problems of preventive psychiatry; the relation of physical and emotional factors; and problems of mother–child separation and hospitalization. A representative selection of twelve case-histories deals in great detail with the various aspects of diagnosis, treatment and prevention, each case being followed by a discussion by experts on the particular problems involved. Contributors and members of the discussion groups were drawn from different countries; but the majority came from the United States. In addition, there are reports on relevant research in progress in which the fundamental concepts, general principles and methodological problems arising from the material are discussed.

The book makes absorbing reading, whether it is the case of the mother who, following her husband's suicide, began to identify her fifteen-months old son with his dead father, causing severe disturbance in the child's development; whether it is the one of pseudo-deafness and retardation in a child who was abandoned by his mother at two months and was moved fourteen times before he was two; that of a four-year old of 'atypical development' who spoke his own language and frightened his parents by acting and gesticulating in an unusual way; or that of a mother whose child would not eat.

Case-histories, interviews and clinical observations afford a glimpse into the complicated nature of emotional problems in the very young child and their ramifications involving the family and the wider environment. They also reveal the difficulties of dealing with these problems in a constructive and planned way by teams of psychiatrists, psychologists and social workers as well as by the numerous social agencies; any of these may be the prime mover in a particular case.

The editor has more or less rewritten the different contributions, and the book reads as a coherent whole.

Apart from its intrinsic value, this work may teach us several lessons. For one thing, it demonstrates the fact that research in child psychiatry and clinical psychology must be based on the thoroughly investigated and well-authenticated individual case, presented in its broadest setting and in minute detail. The emphasis will have to be on description for a long time to come, with theoretical conclusions drawn tentatively, without attempting to generalize. For another, it shows the importance of closest co-operation within the team at all stages as well as of a fair degree of elasticity as to who should direct the case. Rigid rules (such as that the psychiatrist should invariably be in charge; or that mother and child should not be seen together or by the same person)—still prevalent in many child-guidance clinics—seem a disadvantage while our knowledge and experience in this field is still limited and inconclusive.

Both child psychiatry and child psychology emphasize the importance of early childhood experiences for later development; and it is perhaps in the field of the preventive mental health service that we can benefit most in considering the conclusions of this book. Preventive health services in child welfare have made great progress since the Second World War. Expectant mothers and new-born babies get all the physical care medical science regards as essential and beneficial. All stages of feeding, cleanliness, teething, weaning, etc., are carefully prepared and watched over by doctors, clinics and nurses. But no comparable measures are taken in the province of mental development. It is left to the child-guidance clinics to diagnose and treat emotional disturbances at a time when they are already well established and have become, as it were, part of the child's mental make-up. Although there is a growing tendency to refer children under school age to clinics, this is usually done when the symptoms have become too troublesome for the family. The logical course of development would be to introduce certain psychological observations in routine interviews at child-welfare clinics, in pediatric interviews and nursing practice, and to follow up any signs suggesting undue retardation or a potential source of disturbance. The work of Gesell, Ruth Griffiths, and others, proves that this is practicable; and the number of known instances of diagnoses of, say, mental defect when, in fact, they were cases of early schizophrenia, or retardation due to neglect, rejection or separation in early childhood, should make it seem highly desirable.

This is a book that will give ample food for thought to both specialist and layman.

MARTHA VIDOR

RECONSTITUTION OF TOBACCO MOSAIC VIRUS COMPONENTS

By Prof. BARRY COMMONER, JAMES A. LIPPINCOTT, GEORGIA B. SHEARER, ELLEN E. RICHMAN and JIA-HSI WU

Henry Shaw School of Botany, Washington University, St. Louis, Missouri

CHEMICAL explanations of genetic activity call for correlations between the biological activities and specific chemical attributes of a genetic agent. This requires that the components responsible for an agent's several biological activities be separated from each other and from inactive material, and presupposes that the active components will withstand such treatment without undue loss of genetic competence.

In 1947 Schramm reported the first efforts to obtain information of this type from experiments with tobacco mosaic virus. In a series of fifteen reconstitution experiments with mixtures of previously separated tobacco mosaic virus protein and nucleic acid, he experienced two instances of apparently successful recovery of infectivity. However, because of the slight effects obtained and the fact that most experiments were not successful, Schramm declined to consider the phenomenon established[1]. Following subsequent improvements by Schramm of the method of releasing tobacco mosaic virus protein from the virus[2], Fraenkel-Conrat and Williams[3] and Lippincott and Commoner[4] reported the results of independent investigations which led to consistent success in reactivating mixtures of virus ribonucleic acid and Schramm's 'protein a' (prepared by mild alkaline treatment of tobacco mosaic virus). In both cases, the reactivated material was only of marginal infectivity, being no more than one-hundredth as active as authentic tobacco mosaic virus. This fact appeared to preclude extensive use of the reactivation phenomenon as a means of determining the biochemical basis of the genetic activity of the virus. This article describes the partial solution of this problem, and some experiments concerning the relationship between the composition and biological activity of nucleoproteins artificially reconstituted from tobacco mosaic virus protein and nucleic acid.

Tobacco mosaic virus is a hollow rod. Small protein units are arrayed in a flat spiral; nucleic acid strands are in a concentric zone in the rod[5]. When the virus nucleoprotein is treated at pH 10·5 for about 3 hr. in the cold the protein sub-units become dissociated, and may be recovered as separate low molecular weight entities. This preparation may be freed of residual virus by ultracentrifugation and of dissociated ribonucleic acid by adsorbing the latter on a column of modified cellulose ('Ecteola *SF*')[6]. Virus ribonucleic acid may be prepared by the method of Cohen and Stanley[7], and purified by ultracentrifugation and alcohol precipitation.

Low molecular weight protein isolated from tobacco mosaic virus in the manner just described will polymerize (at pH 6, or in 28 per cent ammonium sulphate) to form hollow rods resembling those of ordinary tobacco mosaic virus in size and shape. Such nucleic acid-free rods, like the original low molecular weight protein, are not infectious. Schramm finds that when tobacco mosaic virus is partially degraded with alkali, some of the product consists of virus rods containing intact threads of nucleic acid, which retain an interrupted coat of protein at intervals along their length[8]. Such material appears to be infectious, though weakly so. When these particles are treated with ribonuclease, the enzyme is able to attack the denuded portion of the nucleic acid and the rod breaks and becomes devoid of infectivity[8].

This information suggests some possible causes for the low level of infectivity exhibited by the products of the reconstitution procedures employed in the initial investigations by Fraenkel-Conrat and Williams, and by Lippincott and Commoner. From what is known about the behaviour of tobacco mosaic virus protein and ribonucleic acid, the reconstitution process may be expected to produce: (*a*) polymerized protein lacking nucleic acid, (*b*) nucleoprotein comprising nucleic acid completely coated with protein, and (*c*) nucleoprotein particles in which the protein coat contains small faults. All three types of products may be approximately equivalent in sedimentation behaviour and, without special degradation procedures, will appear to be identical in the electron microscope. However, of these components, only the particles with entire protein coats may be expected to be equivalent to tobacco mosaic virus in infectivity.

With these considerations in mind, an effort has been made to improve the completeness and specificity of the interaction between virus protein and nucleic acid in reconstitution experiments and thereby to enhance the infectivity of the product. Consideration of the probable reaction kinetics suggests the following conditions for optimum formation of active nucleoprotein from tobacco mosaic virus protein and ribonucleic acid.

(1) Reaction mixtures should contain relatively low concentrations of nucleic acid and protein. Joint polymerization is linearly related to reactant concentrations, while self-aggregation of protein (and of nucleic acid) depends on a higher power of the concentration.

(2) To enhance the thermodynamic activity of the reactants, they should be relatively insoluble in the solvent chosen for the reaction mixture.

(3) To avoid gaps in the protein coat of the nucleoprotein polymer, accretion of protein units around the ribonucleic acid should ideally proceed from a single starting point rather than from multiple protein 'seeds'. This requires that reaction mixtures contain relatively low molar ratios of protein to nucleic acid. Nevertheless, the molar ratio of protein : nucleic acid in the virus nucleoprotein is about 2,000 : 1 (the nucleic acid being considered a single molecule) and the reactants need to enter into the product in this proportion.

To reconcile these conflicting demands, protein is added in small amounts over an extended period of time to a relatively low concentration of virus ribonucleic acid dissolved in a medium (28 per cent or

The results of three separate reconstitution experiments. Reactants were prepared as described in the text, the nucleic acid being used immediately after being centrifuged out of 66 per cent ethanol. Nucleic acid was dissolved in the indicated solvent, and protein in aqueous solution was added either immediately or gradually. Simultaneously, sufficient ammonium sulphate was added to maintain the indicated concentration. The temperature was 4° C. throughout. (*a*) Controls were treated in the same way as the mixtures, the material yielded being finally inoculated on leaves of *N. glutinosa*. (*b*) In experiment 3 *C* nucleic acid was dissolved in 62 per cent ammonium sulphate, the concentration of which was gradually reduced to 28 per cent as the protein solution was added. (*c*) Gradual addition of protein was accomplished in eleven portions over a 3-hr. period, except in experiment 1 *A*, in which a 24-hr. period was employed. (*d*) All preparations inoculated on twenty leaves of *N. glutinosa*. In experiments 3 *A*, 3 *B* and 3 *C* only 1/5 of the nucleoprotein was inoculated. In all other cases, all the recovered nucleoprotein was inoculated. (*e*) Equivalent infectivity is determined from the quotient: (lesions from sample/lesions from tobacco mosaic virus standard) × amount of tobacco mosaic virus standard. Tobacco mosaic virus standards (4 μgm.), inoculated on twenty leaves of *N. glutinosa*, yielded 249 lesions in Exp. 1, 774 lesions in Exp. 2, 2,932 lesions in Exp. 3. In all cases, standards and experimental samples were inoculated on randomized groups of the same batch of detached leaves which were maintained in water at 24° C. and constant illumination during lesion formation. (*f*) Specific infectivity (as percentage) is determined from quotient: (equivalent infectivity of sample/amount of nucleoprotein in sample) × 100

more ammonium sulphate) in which the protein is relatively insoluble.

Table 1 compares the results of a reconstitution method based on these considerations with the infectivity of reconstituted nucleoprotein prepared by the earlier technique. Whereas the earlier procedure (experiment 1 *A* in Table 1) yields nucleoprotein less than 1/100 as infectious as actual tobacco mosaic virus, the newer method yields a product which may approach one-tenth of the infectivity of tobacco mosaic virus. These experiments also provide data which firmly establish the authenticity of the reconstitution process: the number of lesions yielded by reconstituted material is about a thousand times greater than the number produced by the uncombined starting materials.

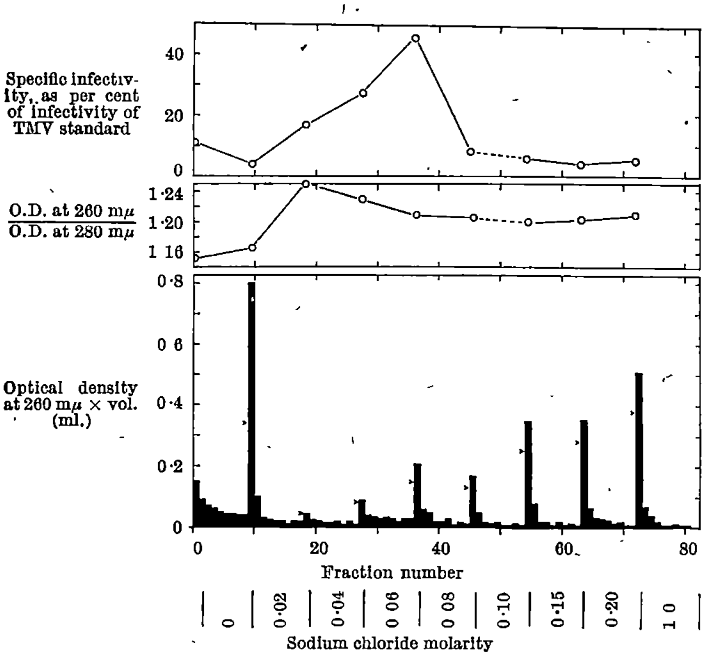

Fig. 1. Fractionation of 6·77 mgm. of reconstituted nucleoprotein by elution from a column containing 182 mgm. of 'Ecteola *SF*'. Eighty-six per cent of the original nucleoprotein was recovered. Elution was accomplished with successively higher concentrations of sodium chloride in 0·01 *M* phosphate buffer, *p*H 7, collected in 2 ml. fractions. The initial 2 ml. fraction obtained after each solvent change was ultracentrifuged to precipitate high-molecular weight nucleoprotein, the amounts recovered being indicated by the arrows. The uppermost and centre curves show, respectively, the specific infectivity (relative to the lesion count given by a standard tobacco mosaic virus solution on opposite halves of *N. glutinosa* leaves), and the ratio of optical densities at 260 mμ and 280 mμ of the nucleoprotein recovered from these initial fractions. The specific infectivity of the original nucleoprotein was 6 per cent of the tobacco mosaic virus standard

The preceding results imply that the gross product of a reconstitution experiment is a heterogeneous population of nucleoprotein entities which differ with respect to nucleic acid content, the completeness of their protein coats and infectivity. This suggests that a fractionation process based on the relative accessibility of the ribonucleic acid of the reconstituted particles might also serve to concentrate the most infectious components. Fig. 1 shows the results obtained when reconstituted material with an original specific infectivity of 6 per cent is adsorbed on an 'Ecteola *SF*' column, and fractions are eluted by successive additions of increasing concentrations of sodium chloride in 0·01 *M* *p*H 7 phosphate buffer. The nine fractions recovered from the column differ in stability, in relative nucleic acid content (as shown by the ratios of optical densities at 280 and 260 mμ), and in infectivity. As expected, the bulk of the material is very low in infectivity. The relatively small fractions eluted with 0·04–0·10 *M* sodium chloride contain most of the infectivity of the original material. The 0·08 *M* sodium chloride eluate comprises nucleoprotein which is about 45 per cent as infectious as ordinary tobacco mosaic virus.

A fractionation comparable to that just described has also been carried

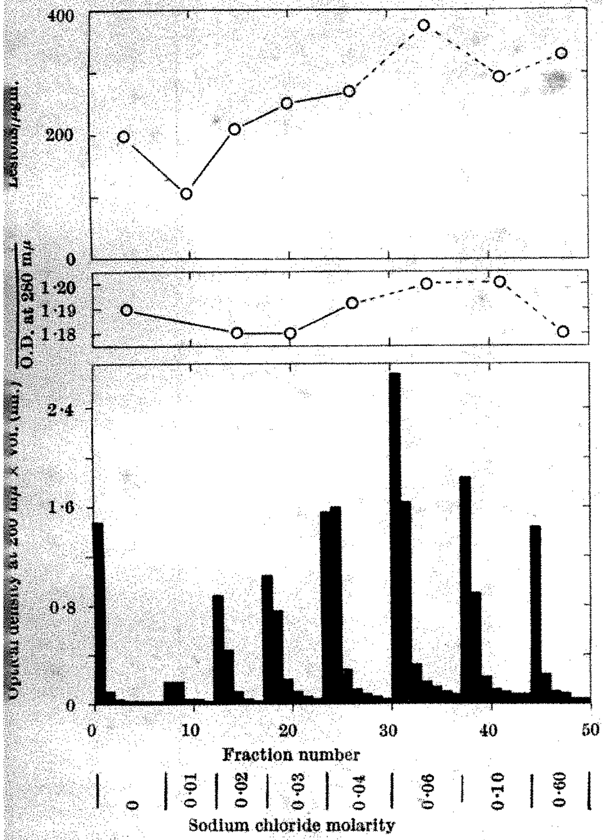

Fig. 2. Fractionation of 8 mgm. of ordinary tobacco mosaic virus on a column containing 500 mgm. of 'Ecteola *SF*'. Elution procedures were as described in the legend for Fig. 1. The fractions collected with each solvent were pooled and the high molecular weight material collected by ultracentrifugation. The two upper curves refer to this material. Total recovery was 96·5 per cent of the original virus

out with the original stock preparation of natural tobacco mosaic virus. The results, which are summarized in Fig. 2, show that ordinary tobacco mosaic virus is heterogeneous with respect to elution behaviour, infectivity and nucleic acid content (ratio of 260 mμ : 280 mμ optical densities).

Comparison of Figs. 1 and 2 shows that the composition of the nucleoprotein populations that comprise natural tobacco mosaic virus and the reconstituted material differ significantly. The major fractions in ordinary tobacco mosaic virus are eluted by 0·04–0·10 *M* sodium chloride; but these fractions represent minimal components in reconstituted nucleoprotein. In both cases, the most infectious nucleoprotein is found in the fractions eluted by 0·06–0·08 *M* sodium chloride. The remaining fractions contribute rather little to the total infectivity of reconstituted nucleoprotein, but in tobacco mosaic virus these fractions are only moderately less infectious than the major component.

This heterogeneity is reflected in the biological properties of reconstituted preparations. An unusual number of aberrant symptoms have been observed in *Nicotiana tabacum* plants systemically infected with single lesions derived from reconstituted nucleoprotein. These include: (*a*) 'strap leaves', leaves reduced to midribs only; (*b*) bright yellow mosaic; (*c*) pale green mosaic followed by necrosis in the mosaic areas; (*d*) circular necrotic lesions on the inoculated leaf. None of these symptoms was found among a comparable number of plants from the same culture generation inoculated with single lesions derived from ordinary tobacco mosaic virus.

These observations suggest that the manipulations incident to the isolation of tobacco mosaic virus protein and nucleic acid and to the reconstitution process may alter the genetic competence of the virus components. Results recently reported by Gierer and Schramm[9] indicate that the biological activity of the virus is at least in part due to its ribonucleic acid. It has been shown that the ribonucleic acid isolated from tobacco mosaic virus is partially dissociated into fragments of variable size, which can be fractionated by elution from 'Ecteola' columns[10]. It is to be expected, therefore, that the nucleic acid which is incorporated into nucleoprotein particles during the reconstitution process may represent fragments of virus ribonucleic acid or various combinations of such fragments, as well as substantially intact virus nucleic acid.

Accordingly, an effort has been made to fractionate the components which occur in preparations of tobacco mosaic virus nucleic acid, and to incorporate them separately into reconstituted nucleoproteins. Ribonucleic acid was prepared in the usual manner and fractionated on an 'Ecteola *SF*' column according to the method of Bradley and Rich[10]. Three fractions, obtained by this procedure, were concentrated by precipitation in 66 per cent ethanol, redissolved in water and polymerized with tobacco

Table 2. INFECTIVITY OF NUCLEOPROTEIN RECONSTITUTED FROM TOBACCO MOSAIC VIRUS (TMV) PROTEIN AND FRACTIONS OF TMV NUCLEIC ACID

Nucleic acid fraction	Reactants[a]		Nucleoprotein recovered μgm.	Nucleoprotein tested μgm.	Total No. of lesions[c]	Equivalent infectivity; μgm. TMV[d]	Specific infectivity; per cent of TMV standard[e]
	Protein μgm.	Nucleic acid μgm.					
(1) Entire, unfractionated	8,580	94	935	750	833	4·75	0·51
(2) 0–0·15 *M* NaCl eluate	13,000	223	1,610	1,290	75	0·44	0·03
(3) 0·15–0·25 *M* NaCl eluate	3,250	130	270	216	28	0·16	0·06
(4) 0·25–0·30 *M* NaCl eluate	1,742	49	105	84	31	0·37	0·38
(5) None (control)[b]	8,580	—	—	—	0	—	—
(6) Unfractionated (control)	—	94	—	—	2	—	—

The nucleic acid (1,543 μgm.), after being precipitated in 66 per cent ethanol, was adsorbed on a column containing 0·5 gm. of 'Ecteola *SF*' and eluted with increasingly stronger sodium chloride solutions in 0·01 *M* phosphate buffer, *p*H 7. About 31 per cent of the nucleic acid was recovered in the sodium chloride eluates, the remainder being removable from the column with alkali. The fractionation required about 8 hr. The unfractionated aliquot was held for this time before reaction with protein; this probably accounts for the relatively low infectivity of the product as compared with the results reported in Table 1. (*a*) Nucleic acid was dissolved in sufficient 28 per cent ammonium sulphate to yield solutions of approximately 1 μgm. of ribonucleic acid per ml. Protein was added gradually over a 3-hr. period. (*b*) Controls were treated in the same way as the mixtures, and the material yielded finally inoculated on *N. glutinosa* leaves. (*c*) All preparations tested on twenty randomized leaves of *N. glutinosa*, except preparation (4), which was tested on ten leaves. (*d*) Equivalent infectivity is determined from the quotient: (lesions from sample/lesions from tobacco mosaic virus standard) × amount of tobacco mosaic virus in standard. In this experiment, 2 μgm. of standard tobacco mosaic virus inoculated on twenty leaves of *N. glutinosa* produced 438 lesions. Other infectivity procedures were as described in Table 1. (*e*) Specific infectivity (as percentage) is determined from the quotient: (equivalent infectivity of sample/amount of nucleoprotein in sample) × 100

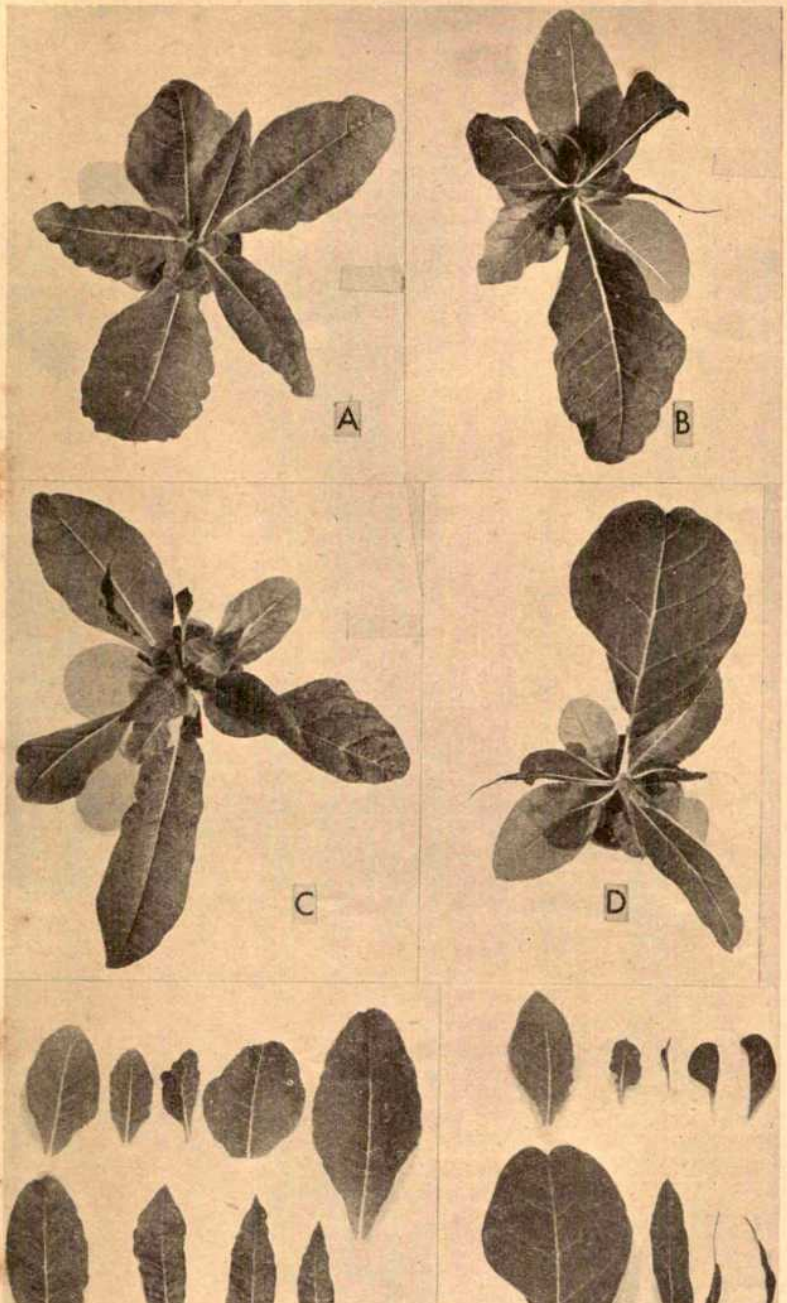

Fig. 3. The effects of infection with reconstituted nucleoprotein prepared from a fraction of tobacco mosaic virus nucleic acid eluted from an 'Ecteola *SF*' column between 0·15 and 0·50 *M* sodium chloride. The photograph shows four plants of the same culture generation two months after being inoculated, respectively, with a single lesion derived from ordinary tobacco mosaic virus (*A*), and with three separate lesions produced by the reconstituted nucleoprotein (*B*, *C*, *D*). Photographs *E* and *F* represent leaves of comparable serial position removed from plants *A* (tobacco mosaic virus) and *D* (reconstituted nucleoprotein), respectively. In *E* and *F*, the most basal leaf is in the upper left-hand corner of the photograph

mosaic virus protein by the method already described. The results are shown in Table 2. In each case the reconstitution process yielded a high molecular weight nucleoprotein (absorption maxima at 260 mμ; minima at 250 mμ; ratios of optical densities at 260 mμ and 280 mμ, 1·17–1·30). These products exhibited infectivity, which varied in level according to the ribonucleic acid fraction employed to form the nucleoprotein.

Lesions produced on leaves of *N. glutinosa* by nucleoprotein derived from various ribonucleic acid fractions eluted from 'Ecteola' columns have been employed to infect a number of plants of *N. tabacum*. Among these plants are some which show symptoms that depart significantly from those ordinarily associated with tobacco mosaic virus infection. Examples are shown in Fig. 3. In these plants apical growth is severely suppressed, and leaf blades become greatly reduced or are absent. The plants contain large amounts of infectious nucleoprotein, which upon being inoculated into White Burley or Turkish tobacco plants induces symptoms like those found in the original infected plants.

In two separate experiments, highly aberrant floral symptoms were found among the plants inoculated with single lesions derived from reconstituted nucleoprotein produced with a ribonucleic acid fraction eluted from 'Ecteola' columns between 0·25 and 0·30 *M* sodium chloride. The infected flowers show a scattered mottling in pigmentation rather than the sharp-edged 'breaks' characteristic of flowers infected with ordinary tobacco mosaic virus, and are remarkably transformed in shape. Uniform and symmetrical suppression of lateral extension of the petals gives rise to a deeply cleft, fringed corolla. Although plants infected with ordinary tobacco mosaic virus sometimes produce flowers with irregularly distorted corollas[11], symmetrical transformations do not occur.

The foregoing results show that reconstitution of tobacco mosaic virus protein and nucleic acid provides experimental opportunities suitable for investigations of the chemistry of genetic competence. The virus nucleic acid, which is at least in part responsible for the genetic specificity of the virus, will withstand isolation procedures without losing its activity. The reconstitution process, while yielding heterogeneous nucleoprotein, is amenable to procedures which enhance the specificity of protein–nucleic acid interaction. By these means and by suitable fractionations it is possible to obtain reconstituted nucleoprotein which has an inherent infectivity approaching that of natural tobacco mosaic virus. Thus, the process appears to be capable of yielding preparations which are sufficiently infectious to enable valid correlations between composition and biological activity.

There is evidence that both the physical and genetic integrity of the virus nucleic acid is disrupted during the process of extraction. As a result, at least some of the nucleoprotein reconstituted from virus nucleic acid and from isolated nucleic acid fractions appears to be genetically different from the original virus.

With further attention to these effects, the reconstitution phenomenon may provide a means for correlating the biological attributes of the virus with the composition of its component parts.

We wish to acknowledge the valuable suggestions made by Dr. Otto Redlich, of the Shell Development Co., in connexion with the kinetics of the reconstitution process. The work reported in this paper was aided by a grant from the National Foundation for Infantile Paralysis, and by a grant from the Rockefeller Foundation.

THE STRUCTURE AND GROWTH OF WOOL

A SESSION of Section D (Zoology) of the British Association meeting at Sheffield was devoted to "The Structure and Growth of Wool and other Animal Fibres"—a symposium that might well have been held jointly with Section M (Agriculture). The subjects of the papers presented ranged from "Fleece Growth", through the detailed consideration of various aspects of individual fibre growth, to the chemical and physical structure of the wool fibre.

Dr. A. B. Wildman (Wool Industries Research Association), whose opening paper, "Fleece Growth", was read by Mr. H. B. Carter, stated that there is developing in Great Britain an increased awareness among sheep farmers of the importance of supporting wool biological research, and applying its results. He said that, briefly, the objectives of research into the biology of wool are to provide knowledge whereby the quality and quantity of any particular type of fleece may be improved. Progress can only be made if wool improvement is clearly defined. This depends on the breed of sheep, district, and flock being considered. For example, in one flock wool improvement may be defined as "the increase of average fleece weight, with maintenance of reasonable fleece uniformity in fibre thickness and other important fleece characteristics". In addition, careful thought must be given to the way such improvement may be realized in a reasonable time.

If, for example, the objective is to raise average fleece weight, then the heritability of fleece weight in the breed in question must be considered. If fleece weight is strongly inherited, then selecting for high fleece weight would give an improvement reasonably quickly. But if this character is weakly inherited, only breeding animals must be selected, particularly the rams, whose progeny have given high fleece weights. Research such as this, based on carefully controlled mating and accurate observation of fleeces at various ages, might be termed 'breeding research'. Dr. Wildman said that there is, however, a second broad category of biological wool investigation, namely, 'fleece or fibre growth research', and he went on to indicate some of the facts about fleece development. The first wool follicles to be formed in the fœtus are known as primary follicles; those formed later are secondaries. The primaries are characterized by the 'possession' of a sweat gland in addition to the sebaceous glands found associated with both the primary and secondary follicles. The primary follicles are all developed before birth, and form follicle groups with their more numerous associated secondaries. Although many secondary follicles are developed before birth, they continue to be developed for some time afterwards, at any rate in British breeds. It was the development of secondary follicles that Dr. Wildman particularly considered, because the densest fleeces often have a higher proportion of secondary follicles, that is, a greater secondary to primary (*S*/*P*) follicle ratio. He outlined the results of investigations designed to show whether environment affects the number of secondary follicles formed, that is, the *S*/*P* ratio, bearing in mind that there are genetic differences in mature *S*/*P* ratio between breeds and within breeds.

Schinckel[1], working with Merinos in Australia, found that single lambs had a higher *S*/*P* ratio at birth than twin lambs. Ryder[2] found a positive correlation between *S*/*P* ratio at birth and body weight at birth in Cheviot lambs with body weights ranging from 8 to 14 lb.; and Dr. Wildman said he had found a similar relation between *S*/*P* ratio at birth and body weight at birth in Romney Marsh lambs with birth weights ranging from 5½ to 15 lb. Thus lambs that suffer nutritional penalty during fœtal life tend to have a lower *S*/*P* ratio at birth. The next question was: Are there any influences between birth and weaning time which affect mature *S*/*P* ratio ? In the Cheviots it was found that mature *S*/*P* ratio is correlated with body weight at birth, and Dr. Wildman showed a scatter diagram illustrating a lack of positive correlation between gain in *S*/*P* ratio and gain in body weight from birth to weaning. With the Romneys, however, a scatter diagram of *S*/*P* ratio at 90 days plotted against birth weight showed a slight trend towards a positive correlation with lambs over 10½ lb., but none with lambs weighing less than this; and when gain in *S*/*P* ratio was plotted against gain in body weight, a slightly positive relation was found. Breeds therefore differ in this respect, and Dr. Wildman thought that part at least of the explanation of this difference between the Romney and the Cheviot may be due to a longer developmental period of secondaries in the Romney. In the Cheviot the follicle population may mature early, and had probably reached the upper genetic limit for the breed before the total number of follicles could be affected by small environmental and nutritional conditions.

Dr. M. L. Ryder (Wool Industries Research Association) then presented a paper entitled "The Blood Supply to the Skin and Wool Follicles of Sheep". He said that there were two main reasons for making a study of the blood supply to the skin. First, it was possible that some explanation for regional variations in the fleece might be found in the blood supply to the skin. The term regional variation is used for describing the difference, for example, between the fine wool of the shoulder and the coarse wool grown on the hinder parts of a sheep. Such variation is hereditary, and in fact no explanation for it was found in the blood supply. Secondly, as more and more experiments showed the extent to which the diet of the sheep can cause the wool to vary, it became important to know the way in which nutrients reach the wool follicle. Such variation was indicated in Dr. Wildman's paper; but one perhaps more obvious difference appears as change in diameter along the length of the fibre.

The first stage of the investigation was to dissect lambs in order to trace the main vessels leading to the skin, which was found to be supplied by numerous small arteries evenly distributed over the body. These vessels enter a network which can be seen on the under surface of a skin after removal. The density of this net was not found to vary greatly in different body regions or between breeds of sheep. Thus, the way in which blood reaches the skin was discovered; but no anatomical differences were found in the blood supply that would account for differences in fleece growth, either over the body or between breeds. This vessel network on the under surface of the skin is the dermal network lying at the base of the dermis.

There are two more networks within the skin and parallel to the skin surface. These are the mid-dermal vessels, lying about one-third of the depth of the skin below the surface, and the outermost net beneath the epidermis. The wool follicles are supplied from the two inner nets, the dermal and mid-dermal vessels.

The immediate supply to the follicle consists of a basket-like net of capillary vessels surrounding the lower third of the follicle, and others which enter the papilla beneath the growing point of the fibre. Blood seems to rise to the peak of the papilla first, and the larger the papilla the more vessels it contains. The surrounding network terminates at the level at which the fibre has become keratinized, and there is a part on one side of the follicle, immediately above the bulb, where the vessels are denser than anywhere else. This may have some association with the bilateral structure of the fibre, which in turn is thought to be connected with the crimp of wool.

Dr. L. Auber (Wool Industries Research Association) followed with a paper on the "Comparison of Development of Fibres and Related Structures". Dr. Auber stated that fibrillary origin is common to all horny structures produced by the epidermis of 'higher vertebrates'. The simplest structure is stratum corneum, from which flat reptilian scales appear to be the immediate derivatives. Cellular elongation and parallel orientation of fibrillary cell-contents occur in certain reptilian scales, the cortex of bird feathers, and mammalian fibres (wool and all types of hair). Both feather barbs and fibres tend to develop axial strands known as medullæ, which are characterized by turgidity during their differentiation and by vacuolization in their fully formed state. On fibres, and usually also on feather barbs, flattened layers of surface cells are found; in fibres they constitute the well-known overlapping cuticular scales.

Feathers and fibres have apparently originated independently although the function of both is thermal insulation. Histochemically, however, they have much in common; this is revealed by their staining reactions. The cortex in both structures tends to pass through successive phases of affinity for acid, basic and nitro dyes, but the medulla stains only with acid dyes. In fibres the progress of differentiation of the cortex varies between species, whereas the progress in feathers follows the general development of the barb from the obverse to the reverse. In wool the keratinization starts at one side, and the progress across the fibre is termed segmental, whereas in straight fibres the progress is periphero-axial, proceeding concentrically. The so-called shield hairs of many aquatic mammals show deviations from periphero-axial progress. In the beaver, for example, the keratinization starts on one side, but does not proceed directly across the fibre: it first spreads around the surface of the cortex.

Mr. H. B. Carter (Agricultural Research Council's Animal Breeding Research Organization) considered the fleece again with a paper entitled "The Determinants of Fleece Structure in the Merino and its Crosses". He said that among several hundred breeds of sheep in the world, the Merino group is perhaps the most important. This group constitutes about one-fifth of the estimated world sheep population and produces about one-third of the world's natural wool supply. During the past two centuries no other breed or group of breeds has been so extensively used for crossing. The distinctive basis of the Merino's fleece structure is a dense follicle population in which the follicle groups tend to be larger than those of any other breed. These large follicle groups are associated with high S/P follicle ratios the values of which range from 5 to 45 secondaries per primary follicle. In all other breeds not obviously related to the Merino the extreme range of S/P ratio is roughly from 2/1 to 10/1. Cross-breeding with the Merino, therefore, tends more than anything else to increase the fibre population of the fleece provided Merinos with large follicle groups are used.

In cross-breeding, the Merino tends to modify fleece structure by reducing wool fibre thickness, fibre length, medulation, and the output of water-soluble skin secretions even when these characteristics are strongly expressed in the breeds with which it is crossed. Conversely, it tends to increase not only fibre population density but to enhance the expression of skin wrinkles and folds, and the output of sebaceous (mostly ether-soluble) skin secretions. All these characters in the cross-breds tend to have values intermediate between the parental breeds. Characters associated with the follicle group in the skin appear to have moderate to high heritability values and hence may respond well to direct selection. The biological origin of the prototype Merino is still obscure, and Mr. Carter stressed the importance of solving in genetic terms the problem of the origin of the very large follicle group which seems to be a special feature of Merino types. Its solution could help greatly in clarifying the aims and practice of sheep breeding for the improvement of wool production.

Dr. F. Happey (Technical College, Bradford) took the audience abruptly from sheep to molecules by presenting a paper entitled "The Fine Structure of the Protein Fibres". This dealt with physical studies of the structure of protein molecules. Dr. Happey said it is clear that any advances made in the elucidation of their complex nature have only been achieved by considering their aggregations in conjunction with those of other related long-chain molecules. In polypeptides the specific properties appear to depend upon the sequence of the amino-acids in the chain, and the folding of the molecule. It appears from X-ray diffraction pictures that there is structural similarity between synthetic and natural polypeptides.

When the stabilizing S—S link of wool has been broken by oxidation, about 90 per cent of the fibre can be dissolved in weak alkali, leaving an insoluble matrix. The soluble phase can be regenerated and the resulting filaments are usually in the alpha configuration. This appears to confirm the findings from synthetic polypeptides that the alpha form is not necessarily a product of specific biosynthesis[3]. The same physical methods have shown a web structure in the wall of the human intervertebral disk. Here the protein is made up of crossed sheets of collagen fibrils which form a cylindrical elastic membrane enclosing, ideally, a gelatinous matrix of collagen and polysaccharide to form a 'shock absorber'. In conclusion, Dr. Happey said that he had tried to show the breadth of the application of physico-chemical methods to fibrous materials. We are, however, still on the fringe of the biophysical problem of protein structure. The physicist, he said, is well aware of his limitations and needs to be constructively criticized by the biologist to ensure that he does not miss the fundamentals in a mass of classical biological data. Nevertheless, such collaboration is achieving progress in this vital study of the proteins.

RECENT ANTARCTIC RESEARCH

A LARGE audience attended the joint symposium on "Antarctic Research" held by Sections C (Geology) and E (Geography) of the British Association in the Firth Hall, University of Sheffield, on September 4.

Sir Raymond Priestley, who acted as chairman, emphasized three aspects of the progress of geological research in the Antarctic. First, he noted the extreme good fortune of the early expeditions, the bases and journeys of which were situated in those parts of the continent where many of the key horizons were accessible. In consequence, the outlines of Antarctic palæontology and palæoclimatology had been traced before 1915 and later exploration had little modified the conclusions deduced from these early discoveries.

Secondly, Sir Raymond noted the absence of important economic discoveries apart from the early finds of thin coals in the Permo-Carboniferous Beacon Sandstone of the Ross Dependency. He emphasized the necessity of luck in finding chance outcrops containing ore deposits, but ventured to predict that the exposures of the Basement Complex on the western shores of McMurdo Sound, which is the proposed site of the New Zealand base for the Trans-Antarctic Expedition, might prove to be the most promising locality for seeking metalliferous ore deposits.

Sir Raymond Priestley then emphasized the burden placed upon the field scientist by the routine commitments of expedition life. He noted the necessity for the geologist to travel many miles to examine outcrops at the end of a strenuous day's travelling; for the surveyor to lose sleep in order to obtain astronomical observations.

Sir Raymond's principal criticism of British expeditions during the past thirty years was their failure to provide a full-time and competent cook for each party. He noted the grave disadvantages which arose when a scientist was forced to interrupt his programme in order to take his share of the cooking. The present writer supports this criticism, having, in two years, spent twenty-eight weeks cooking at the expense of all other activities.

Sir Raymond emphasized the financial difficulty which nearly every expedition has faced in attempting to publish the results of its field-work. In contrast, he noted the establishment of the Falkland Islands Dependencies Survey Scientific Bureau in 1950 as a determined effort to integrate the different studies carried out by this Survey during the post-war decade.

Sir Raymond Priestley then introduced Dr. V. E. Fuchs, the leader of the 1955–58 Trans-Antarctic Expedition.

Dr. Fuchs emphasized that although the first voyage of the *Theron* had established the base known as 'Shackleton' in Vahsel Bay, the field party has so far accomplished little scientific work. Indeed, the loss of the chemicals for generating hydrogen when the sea-ice broke up during the autumn had been a grievous setback which would delay the radiosonde programme for a whole year.

He spoke at length about the proposed scientific programme and showed how this would dovetail with the prime object of the transcontinental journey. Dr. Fuchs noted the value of aircraft for reconnaisance, for depot-laying and as a safety factor in Antarctic travel, but emphasized the limited value of observations from aircraft without adequate ground control. The prime scientific aim of the mechanized trans-continental party will be the maintenance of continuous seismic and gravity traverses across the inland ice to measure the thickness of the ice and ascertain the underlying topography.

It is hoped that much of the more specialized glaciological and physiological research will be carried out at the 'Advance Base' which it is hoped may be established some three hundred miles south of Vahsel Bay. Precise plans will, however, depend upon the accessibility of the inland ice. The flights of the Auster aircraft from Vahsel Bay last summer led to the discovery of an extensive mountain range about two hundred miles south of 'Shackleton'. Dr. Fuchs suggested that the possible continuity of this range with the mountains of Dronning Maud Land and its supposed extension towards Graham Land may considerably modify the plans of the Expedition. Although this difficult mountain terrain might be crossed by parties using dogs or man-hauling, this country might prove impassable to tracked vehicles. The presence of these mountains on the direct route southwards might necessitate a detour of several hundred miles.

Dr. Fuchs then showed a number of colour slides illustrating the voyage through the Weddell Sea and the establishment of the base at Vahsel Bay. Although he discussed some of the problems of navigation through heavy pack-ice, the writer suggests that Dr. Fuchs tended to minimize the difficulties of approaching Vahsel Bay. The *Theron* is only the fourth ship to reach the Filchner Ice Shelf, the annual variations of pack-ice in the Weddell Sea are still little known and the success of the Trans-Antarctic Expedition still depends primarily upon the ice conditions in the Weddell Sea next summer.

The third contribution to the symposium was made by Dr. R. J. Adie (Department of Geology, University of Birmingham), who read a paper entitled "Geological Research in Graham Land".

Dr. Adie briefly reviewed the state of knowledge about the geology of Graham Land before the field investigations of the Falkland Islands Dependencies Survey commenced in 1944. He showed a series of maps which demonstrated the extent of the researches of earlier expeditions and then showed a remarkably complete geological map resulting from the post-war journeys. Dr. Adie summarized, in turn, the characteristics of the various formations which have been studied. These include: (1) The Archaean Basement Complex of Marguerite Bay. (2) The Trinity Peninsula Series of north-east Graham Land, comprising greywacke facies sediments which suffered cataclastic deformation in pre-Jurassic times and thermal metamorphism around the Andean intrusions of early Tertiary age. (3) Mesozoic sedimentary rocks of north-east Graham Land and Alexander I Land which have yielded abundant fossils. These range in age between Middle Jurassic (Hope Bay) to Upper Cretaceous (James Ross Island). The Upper Jurassic–Lower Cretaceous conformable succession in Alexander I Land is contemporaneous with a period of igneous activity in Marguerite Bay. (4) Tertiary igneous rocks which are represented by the Andean granite-gabbro suite (constituting at least 90 per cent of the peninsula); this is considered to have an Early Tertiary age, followed by at least two lava and three volcanic phases in Miocene times.

Dr. Adie was able to demonstrate that the recent work of the Falkland Islands Dependencies Survey has further reinforced the belief of Suess that the Graham Land peninsula is linked with the Andean fold range by the Scotia Arc. Dr. Adie was unable to provide any new evidence to show the relationship of Graham Land with the rest of Antarctica.

Dr. Adie was followed by Dr. D. H. Maling (Department of Geography, University College of Swansea), with a paper entitled "Some Geographical Results of the work of the Falkland Islands Dependencies Survey".

Dr. Maling reviewed the work of the Survey since its inception as a small naval operation in 1944. By means of a series of diagrams he was able to show how the size and interests of the Survey had grown from two bases, manned by fourteen men in 1944, to ten bases with seventy-six men in 1956. He further showed that the total effort of the wintering parties represented 339 man-years and subdivided these figures to represent the work done in the different branches of research at the different bases. In particular, the routine work at the smaller bases received special emphasis.

Dr. Maling was able to show that the meteorological observations of the Survey were of prime importance because these had been made at every base throughout its occupation. There are now several bases where nine or more years of continuous observations have been maintained. The value of such climatic data is considerable for, with the exception of the long-established stations at Laurie Island, South Orkneys, and Grytviken, South Georgia, there were formerly no places in Antarctica where observations had been made for more than two consecutive years. To-day we have a clear idea of the range and variability of the climate of Western Graham Land.

In addition, the relatively close network of stations in the South Shetland Islands and West Graham Land allowed synoptic analysis of the weather in Drake Passage and the Falkland Islands Dependencies. Nevertheless, Dr. Maling introduced a note of caution in the interpretation of these observations. Not one of the Falkland Islands Dependencies Survey bases could be said to have good meteorological exposure. Surface winds, in particular, were considerably affected by local topography and this added to the difficulty of drawing reliable synoptic charts. In view of these difficulties, it is a matter for regret that radiosonde ascents were not made from any of these bases until 1955.

Dr. Maling then turned to other routine observations carried out at each base. He noted that there was now a considerable amount of information about the seasonal movements of sea-ice and the dates of winter freezing of the sea. The analysis of this would have great practical value and would reinforce the summer observations made by the whaling fleets in the open ocean. He regretted the almost complete absence of any routine glaciological work and emphasized that useful observations could be made at every base with relatively limited equipment. With the exception of 1949, when observations of glacier regime were made in both the South Shetland and South Orkney Islands, there were scarcely any quantitative figures for accumulation and ablation.

Dr. Maling then considered the state of topographical surveying in the Falkland Islands Dependencies. The outlines of the main island groups and the coast of western Graham Land were surveyed before the War and, indeed, much of the remaining country had been seen from the air before 1940. Nevertheless, the earlier surveys were largely coastal surveys, and Falkland Islands Dependencies Survey surveyors have made detailed topographical maps of the peninsula and the interior of many of the larger islands. In particular, three important sledge journeys, made during 1946 and 1947, carried accurate ground survey from Hope Bay to the western edge of the Filchner Ice Shelf throughout the length of eastern Graham Land, which was hitherto unmapped. There are, however, many places where the existing surveys are inadequate and the methods by which these areas might be mapped depend upon the accessibility of the Graham Land plateau from the coast. Although aerial photography might appear to provide the quickest method of completing the work, the unreliable weather of the Antarctic inevitably causes difficulty and delay. The lack of success of Hunting Aerosurveys, Ltd., during their first season's operation from the South Shetlands, was largely owing to the bad flying weather during January and February 1956.

Dr. Maling concluded by stating that the work of the Falkland Islands Dependencies Survey is concentrated upon routine observations and careful systematic investigation of the more accessible parts of the Dependencies rather than seeking to make dramatic discoveries in the continental interior. To a certain extent, this policy has been dictated by the political expediency of maintaining continuous residence ; but, from a scientific point of view, such a policy is most desirable, for the continuity of routine observations cannot be achieved in any other way. In this sense, much of the work of the Survey has the same monotonous unspectacular quality as the patient marine research of Discovery Investigations between the Wars.

Dr. Maling was followed by Mr. H. H. Lamb, of the Meteorological Office, who spoke on "Winds and Weather" in the Antarctic. Mr. Lamb's work on the synoptic meteorology of the whole continent is inevitably conjectural owing to the paucity of observations in east Antarctica. Nevertheless he has been able to compile synoptic charts for the summer months when whaling fleets are active, and these charts show much greater variability in the pressure systems than has hitherto been acknowledged. Indeed, the glacial anticyclone of Hobbs is largely mythical and although high-pressure systems occur over east Antarctica for perhaps 85 per cent of the year, these tend to break down and frontal activity affects all parts of the continental interior. Mr. Lamb noted that the high-pressure systems seldom develop sufficiently to move northwards and block the general westerly circulation along the polar front, but it is possible that since his examples were largely based upon summer observations, this feature may be more common in winter. He further noted the asymmetrical arrangement of pressure around the continent and observed that there may be a semi-persistent trough line which lies between the Weddell Sea and Ross Sea. He ventured to predict that if the trans-continental party were forced to travel westward of their direct route, they might be confronted with persistent head winds.

Mr. Lamb then discussed possible reasons for abnormal wind speeds in certain parts of Antarctica. He showed some maps which expressed the frequency of gales in different parts of the continent and showed that the persistent Adelie Land gales could only be caused by some topographical effect. He attributed this to 'frontal funnelling' or the concentration of air-flow between a mountain barrier and frontal surface. Observations in Greenland and comparison with the local winds of the Mediterranean suggest that abnormally high winds may be caused for a considerable distance downwind of the mountains, and he concluded that the gales experienced in Adelie Land may well result from an unrecorded mountain range in the continental interior.

The paper by Dr. W. Campbell Smith (British Museum (Natural History)), entitled "Some Geological Results of the Expeditions to South Victoria Land up to 1914", was taken as read, owing to lack of time.

D. H. Maling

ANTI-OXIDATION

THE importance of antioxidant chemistry to technology was emphasized by the fact that during the British Association meeting in Sheffield, on August 31 a full morning session of Section B (Chemistry) was devoted to papers on this subject. Quite apart from its fundamental value in understanding oxidation processes, the advances in the field of the chemistry of antioxidants have played an important part in the development of high-performance petrols and lubricating oils, in the prevention of oxidative deterioration of rubbers and plastics, in the preservation of foodstuffs and in other processes in which air oxidation gives rise to undesirable effects.

The session was opened with an introductory paper by Prof. C. E. H. Bawn, who reviewed the fundamental concepts and the chemistry of the types of molecules which readily undergo antioxidation in the liquid state in air or in solution at ordinary temperature. Recent research, he said, has been particularly successful in providing a clear picture of the course of the oxidation reaction, and certain generalizations have emerged from this work. The more important of these are that the oxidation occurs by a chain reaction which may be initiated either by oxygen or a catalyst and that the reaction of oxygen occurs without the breaking of the O—O bond to form a hydroperoxide. The reaction chain has been established to be of the following type :

$$\begin{array}{ll}
\text{Initiation} & R\text{H} \rightarrow \text{free radical } R \\
\text{Propagation} & \left\{\begin{array}{l} R + \text{O}_2 \rightarrow R\text{O}_2 \\ R\text{O}_2 + R\text{H} \rightarrow R\text{OOH} + R \end{array}\right. \\
\text{Termination} & \left.\begin{array}{l} R + R \rightarrow \\ R + R\text{O}_2 \rightarrow \\ R\text{O}_2 + R\text{O}_2 \rightarrow \end{array}\right\} \text{inactive products}
\end{array}$$

in which RH = hydrocarbon, aldehyde, etc.

The decomposition reactions of the initially formed hydroperoxide are the source of many diverse substances such as aldehydes, esters, acids, alcohols, etc., some of which are responsible for the development of undesirable properties. For example, rancidity of fats is usually attributed to the formation of aldehydes ; the modification and deterioration of rubbers and plastics, which is manifest by a change in mechanical properties, is a result of oxidative scission of the high-polymer molecules by radicals formed in the hydroperoxide decomposition reaction.

Salts of heavy metals, which are widely known to promote oxidation, are usually present in minute amounts in processed or refined materials and act by decomposing the hydroperoxide into free radicals ; for example :

$$R\text{OOH} + Me^{2+} \rightarrow R\text{O}_2 + \text{H}^+ + Me^+$$
$$R\text{OOH} + Me^+ \rightarrow R\text{O} + \text{OH}^- + Me^{2+}$$

The function of the antioxidant is to inhibit or retard the oxidation reaction, and this is attained either by interruption of the reaction chain leading to hydroperoxide formation or by influencing the hydroperoxide decomposition reactions in such a way as to form products which no longer act as chain initiators. The most commonly used antioxidants are substances which react with the transient RO_2 radicals. These compounds usually, although not invariably, possess a readily removable hydrogen atom, and one of the principal reactions by which antioxidant effects are achieved is:

$$RO_2 + AH \rightarrow ROOH + A$$

The radical A formed from the antioxidant AH is unable to continue the chain reaction and disappears either by reaction with itself or another RO_2 radical. Much evidence supports this mechanism for a number of phenols and amines, which are the two main types of compounds used as inhibitors. The structure of the phenol or amine has a considerable influence on its effectiveness as an inhibitor, and many features of the reaction are still not fully understood. The pro-oxidant effects of trace metals mentioned above may be overcome by addition of substances which chelate with the metal ion and render it inactive.

The problems associated with particular aspects of the use of antioxidants in industry were presented in three papers dealing respectively with the food industry (Dr. C. H. Lea), the oil industry (Mr. C. N. Thompson) and the rubber industry (Mr. J. T. Watts).

Dr. Lea said that many constituents of food such as unsaturated fats, fat or water-soluble vitamins, colouring and flavouring matters react with atmospheric oxygen during the period between preparation and consumption. In the plant or animal these processes are kept under control by a complicated enzymatic process, but in the dead tissues or in food processed from them degradative reactions occur. These reactions, which are believed to occur via a peroxidic mechanism similar to that mentioned above, lead to the spoilage of foods. Although this tendency is opposed by natural antioxidants associated with the foodstuff, many of these materials are removed during processing and refining. The natural antioxidants—of which phenols constitute the largest number—are of particular importance to the food industry, and many have been isolated and identified. Of these, tocopherols (vitamin E) are best known and occur widely in vegetable and animal fat-containing tissues. Other naturally occurring phenolic antioxidants include dihydrocaffeic acid, flavones, tannins and catechol derivatives. Many acidic substances such as citric or phosphoric acids, which themselves possess no antioxidant activity, influence very considerably the activity of phenolic inhibitors either already present or added to food. Such 'synergists' include cephalin, ascorbic acid and other organic acids.

It was pointed out by Dr. Lea that the requirements for a successful antioxidant for use in food are very strict, in that in addition to producing a useful degree of stabilization it must be non-toxic before and after oxidation, be adequately dispersable and must impart no colour, odour or flavour. The conditions are attained after prolonged and extensive testing and even then a very wide margin of safety is specified. Only in recent years has the use of chemical antioxidants been approved in Britain, although their use is extensive in certain countries abroad and particularly in the United States.

In discussing the use of antioxidants in the oil industry, Mr. Thompson said that during the past twenty or thirty years, advances in the field of antioxidants have played a vital part in the great strides made in the development of high-performance oil products. As judged by the papers published on the subject, the amount of research work on antioxidants has continued to increase steadily over this period, and the pace was virtually uninterrupted during the Second World War.

About ten million pounds' worth of antioxidants is used every year in petroleum fuels and lubricants to ensure that they have adequate oxidation stability for the jobs that they have to do. This amounts to nearly 50,000 tons per annum, more than 90 per cent of which is used in lubricants. There are many kinds of antioxidant. The type selected for use in a particular product depends on the nature of the oil product itself, and on the conditions of oxidation likely to be met in service; for example, operating temperatures and amount of contact with air and engine or equipment parts made of copper and iron, which are powerful catalysts of oxidation. Tiny amounts of antioxidants can effectively reduce or completely stop oxidation for long periods, fifty-fold improvements in stability being common.

Two or more kinds of antioxidant may be used together in an oil product to combat the various oxidation influences. The amounts needed vary greatly with the severity of service requirements. The petroleum industry manufactures an enormous number of oil products, and great care has to be taken to ensure that the best oil product/antioxidant combination is available for each of a wide variety of purposes. This is achieved by making use of the knowledge that has been gained in recent years of antioxidant behaviour. For example, different oil products do not respond equally well when the same antioxidant is added to them, and some can be improved in their oxidation-resistance much more than others. Moreover, the effectiveness of some antioxidants varies enormously according to the conditions under which oxidation is occurring. An antioxidant which is superior to others under one set of conditions may not be the best in different circumstances.

Studies involving the assessment of antioxidant activity during the service life of an oil product are valuable in indicating oil-change periods or the need for better products to withstand the more severe conditions to be expected in the future. Extensive field-trials are imperative to supplement laboratory experiments. As to the future trends, the jet engine will impose new demands on the oxidation stability of both lubricants and fuels. It is expected, for example, that in supersonic aircraft capable of 1,500–2,000 m.p.h., the fuel may have to be used to provide not only the power but also the cooling that will be necessary to overcome the thermal barrier.

In introducing the subject of the use of antioxidants in the rubber industry, Mr. Watts referred to the wide range of materials both synthetic and natural which are now available to the industry, and to the basic methods of processing and vulcanization. The important antioxidants now in general use belong to two groups of chemicals, namely, (*a*) amines and their derivatives, and (*b*) phenols and their derivatives, the essential difference in performance of the two types being in the degree of staining imparted to the vulcanizate. He summarized the properties of the amine derivatives as regards their behaviour towards natural ageing, heat ageing, flexing, staining and metal impurities in terms of the broad classification of ketone–amine condensates, aldehyde–amine condensates and secondary aromatic amines. Phenols and their derivatives are mainly of interest on account of the low degree of staining which they impart to the vulcanized rubber. Copper salts, in small amounts, are usually introduced into rubber via the raw materials or in processing, and since these salts are powerful oxidation promoters, it is essential to use copper inhibitors to ensure satisfactory service use of the rubber. Heat and light increase the rate of oxidation, the effect of heat being an increase in stiffness and a decrease in elongation, while light causes crazing due to the production of an inelastic skin. It is essential to add suitable antioxidants to delay these effects. Also the use of anti-flex cracking antioxidants is one of the most important branches of rubber chemicals, their importance arising from the demands of the tyre industry. Amines and their derivatives such as phenyl-β-naphthylamine, diphenyl-*p*-phenylene diamine and dimethoxy phenylene diamines are effective antioxidants for the purpose.

Ozone in minute quantities is one of the most powerful agents for producing cracks in strained rubber, and the concentration normally present in the atmosphere is sufficient to produce cracking. Various methods have been proposed for overcoming this problem, such as the use of wax or varnish film on the rubber. Phenylene diamines in concentrations of 2–4 parts for 100 parts rubber hydrocarbon have been claimed by the Americans to give good protection against ozone. These are used together with other antioxidants. C. E. H. Bawn

NEWS and VIEWS

Psychology at Reading: Prof. M. D. Vernon

Dr. M. D. Vernon, who has been appointed to succeed Prof. R. Oldfield (*Nature* of June 16, p. 1109) in the chair of psychology in the University of Reading, has not only gained an international reputation among students of visual perception as an experimenter, but also has had long and wide experience of psychological work in the field, particularly in industrial and social connexions, and in the study of children. A scholar of Newnham, she was placed in Class I of the Natural Science Tripos and started research in the Cambridge Psychological Laboratory under Mr. (later Sir Frederic) Bartlett in 1922. She remained at Cambridge until 1946, as a member of staff, at first of the Industrial Health Research Board and later of the Medical Research Council. Her earlier work was chiefly in the field of industrial psychology, in which her father, the late Dr. H. M. Vernon, is remembered as an outstanding pioneer. From 1927 onwards she was engaged in a series of studies of visual perception, of uncommonly solid and coherent character. Apart from the scientific value of her findings, these set a standard of patience and rigour which her students and colleagues could not fail to appreciate. During the same period she produced two major works, "Visual Perception" (1937) and "Further Studies of Visual Perception" (1952), the sound scholarship of which have guided and helped those of like interest everywhere. She joined the Department of Psychology at Reading as lecturer in 1946, and became reader in 1956. Dr. Vernon has performed numerous and varied services to her colleagues and her subject, notably as assistant to the editor of the *British Journal of Psychology* during 1932–48, as president of the Experimental Psychology Group during 1952–54, and as president of the Social Psychology Section of the British Psychological Society during 1948–49. Her active interests, backed by full experience in teaching, research and administration, promise a fruitful development of the Reading Department along the catholic yet distinctive lines impressed upon it by the first holder of the chair, Prof. A. W. P. Wolters.

Organic Chemistry in Sydney: Prof. C. W. Shoppee, F.R.S.

The appointment is announced of Prof. C. W. Shoppee to the chair of organic chemistry in the University of Sydney, in succession to Prof. A. J. Birch. Prof. Shoppee's earliest researches were carried out in 1923 at the Imperial College of Science and Technology, London, under Dr. C. K. Ingold, with the nominal direction of the late Sir Jocelyn Thorpe. In 1924, he accompanied Prof. Ingold to the University of Leeds, and in 1928, after having held an 1851 Senior Studentship, was appointed to the staff of that University. In 1939, he was elected to a Rockefeller Research Fellowship, which he chose to hold in the Laboratory of Prof. T. Reichstein at the University of Basle. In 1944 he was appointed to a readership in chemistry in the University of London, tenable at the Royal Cancer Hospital, and, in 1948, to the chair of chemistry in the University of Wales, at University College, Swansea.

Prof. Shoppee is distinguished for his contributions to organic chemistry, and especially for his work in collaboration with Prof. Reichstein on the hormones of the adrenal cortex, which led to the establishment of the detailed structures of these physiologically important compounds. At the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), he applied his special knowledge of the microchemical and chromatographic investigation of natural products to problems of the isolation and identification of endogenous carcinogenic substances present in human tissues. In the steroid field, Prof. Shoppee rapidly gained an international reputation, and his later work involved application of the newer conceptions of the mechanism of organic reactions to the determination of chemical configuration in natural products, an ultimate aim being to illuminate the highly specific relationship between molecular configuration and physiological activity. These aims he has continued to pursue at University College, Swansea, where he has been successful in building a vigorous school. In collaboration with Dr. K. W. Sykes (now professor of physical chemistry at Queen Mary College, London), he was able to promote work on high-temperature kinetics, and more recently has introduced fundamental and applied infra-red spectroscopic studies in association with Dr. H. E. Hallam, and, finally, the complementary study of Raman spectra, in association with Dr. D. A. Long. Prof. Shoppee was elected to the fellowship of the Royal Society in March of this year.

E. B. Wilson (1856–1939)

One of the most distinguished of pioneer experimental embryologists, Edmund Beecher Wilson was born in Geneva, Illinois, a hundred years ago on October 19, 1856. He was educated at Antioch College, Ohio, at the Sheffield Scientific School, Yale, and at Johns Hopkins University, where he obtained the Ph.D. in 1881. In 1885 he became professor of biology at Bryn Mawr College, Pennsylvania. After spending a year in Europe, where he worked with Theodor Boveri at Munich and with Hans Driesch and C. Herbst at the Naples Zoological Station, Wilson was invited by Henry Fairfield Osborn in 1891 to take the post of adjunct professor in the newly established Department of Zoology at Columbia University, New York; he was appointed Da Costa professor of zoology there in 1914. In his first important work, "The Development of Renilla" (*Phil. Trans. Roy. Soc.*, 1883), he made skilled use of serial sections, which were just coming into practice. "The Cell Lineage of *Nereis*" (1892) aroused the interest of American workers in this field of research. In 1901 Wilson showed that accessory asters (T. H. Morgan's "cytasters") form in fertilized *Sphaerechinus* eggs under the influence of hypertonic sea water. From 1903 onwards he concentrated his attention on the chromosomes, particularly on their behaviour during the maturation of the germ-cells, and one of his graduate students, W. S. Sutton, pointed out that the manœuvres of the chromosomes furnish the mechanism for Mendel's two laws of heredity. Wilson's book, "The Cell in Development and Heredity" (1896, third ed. 1925), rapidly became a classic. Of the numerous honours that he received it may be mentioned that he was a foreign member and Croonian Lecturer of the Royal Society, gold medallist of the Linnean Society, and president of the New York Academy of Sciences, the American Academy of Arts and Sciences, and the Society for Experimental Biology and Medicine. A scientist who combined to a remarkable degree artistic workmanship with balanced judgment, and a quiet, cultured gentleman, Wilson died on March 3, 1939, at the age of eighty-three.

L. G. Groves Memorial Prizes and Award

The L. G. Groves Memorial Prizes and Award, given annually from a grant of money placed at the disposal of the Air Ministry in 1946 by Major Keith Groves, J.P., and Mrs. Groves, of Maughold, Isle of Man, in memory of their son, Sergeant Louis Grimble Groves, a meteorological observer who lost his life on a weather flight in 1945, have been awarded this year as follows: *L. G. Groves Prize for Aircraft Safety:* Wing Commander F. Latham, of the R.A.F. Institute of Aviation Medicine, for research into the physiological factors involved in the abandonment of aircraft and in particular the effects of explosive ejection upon the human body; *L. G. Groves Prize for Meteorology:* F. H. Bushby, senior scientific officer, Meteorological Office, Dunstable, where as a member of the forecasting research team of the Napier Shaw Laboratory, Dunstable, he has worked with marked success on dynamical problems and especially on the applications of the equations of fluid dynamics to forecasting, using electronic computing machines; *L. G. Groves Award for Air Meteorological Observers:* Flight Sergeant J. D. Moyes, for meritorious work while serving as an air signaller on meteorological duties with No. 202 Squadron, having completed some 220 meteorological flights totalling nearly 2,000 flying hours.

Proposed Expansion of the La Jolla Campus of the University of California

At a meeting of the Regents of the University of California, held in Berkeley last August, it was decided to expand the University's campus at La Jolla, near San Diego in southern California, including also the Scripps Institution of Oceanography at La Jolla which has been a part of the University since 1912. The Regents agreed that the expansion should take place gradually over a period of years and that it should be based on the growth of the existing facilities at La Jolla for undergraduate instruction and advanced work in mathematics, physics, chemistry and the earth and biological sciences. In this way it is hoped that the rapidly increasing human and material resources of the southernmost part of California will be more fully marshalled for the betterment not only of the University but also of the State of California and the United States generally. In welcoming the new plan, the director of the Scripps Institution, Dr. Roger Revelle, said that the expansion of the University's activities in the San Diego region can be expected to bring great material and cultural benefits to every part of the community; the development will necessarily have to be carried out carefully and slowly, and generous private endowments and ample public funds will be necessary.

Siemens–Ediswan Research Laboratories

Plans have recently been made for new Siemens–Ediswan Research Laboratories which will serve the research activities of Siemens Brothers and Co., Ltd., and of Edison Swan Electric Co., Ltd., the scope of the work being the whole field of telecommunications and various aspects of cable research. It has been decided to erect a group of buildings on a 3½-acre site at Harlow, at the junction of Edinburgh Way and No. 1 Avenue. The first stage of the building plan, which it is hoped to complete in two years, includes three single-story laboratories and one three-story block containing entrance hall, conference room, lecture room and library, as well as laboratories and offices. This will provide accommodation for a total staff of 100–150. Later stages are envisaged in which the three-story building will be increased to five stories, the single-story buildings will be increased to two, and at least three additional structures will be erected. It is not proposed to concentrate the whole of the research staff at Harlow. Sections of the Laboratories will continue to operate near the main factories at Woolwich, Sunderland and Lydbrook. Dr. G. W. Sutton, director of research and education, Siemens Brothers, Woolwich, has been appointed director of the new laboratories.

Land Utilization of Cyprus

Geographical Publications, Ltd., have published a Land Utilization Map of Cyprus in the World Land Use Survey, directed by Dr. L. D. Stamp. The map constitutes an excellent record of the use made of the Island's land about 1949 and, unless great changes are made quickly, it is likely to stand for several years more. The generalizations necessitated by the use of a short key and by the scale of the map (4 miles to 1 inch) tend to simplify the picture unduly, and it says much for the ingenuity displayed in the preparation of the map, for it is not an easy matter to determine the land use and plot the data from a study of about 10,000 air photographs. Those who know Cyprus will be aware of the meaning to be attached to such mixed categories as "tree and other perennial crops with unimproved grazing land"; but those who do not are liable to draw incorrect conclusions unless they have been forewarned. The Island's land is about equally divided between crop land and unimproved grazing land and forest together, which says much for the persistence and patience of the Cypriots who cultivate the land, often with simple implements, and also for the work of the Forestry Department which has been enabled, by legislation and other methods, to do so much for the re-establishment of the forests. Changing age-old methods of cultivation and overcoming fragmentation of holdings makes the Agricultural Department's task more difficult. The map is well produced, and clearly printed so that detail can be seen without difficulty.

Distribution of Mistletoe

A SHORT account of the way mistletoe is distributed is given by D. J. Cove in *The Starfish*, the journal of the Association of School Natural History Societies (No. 9; July 1956). The inquiries started in the Bishop's Stortford district and have now developed into a national survey. Tentative conclusions show that mistletoe is mainly found in old trees and indicate that man, rather than birds, is the chief agent in distribution. On the larger trees, mistletoe tends to grow near the apex of the crown, or towards the sides, where it is beyond the easy reach of man. One possible explanation for this, which does not involve man, is that the light is too weak in the centre of the tree for photosynthesis in mistletoe to take place. Another explanation is that the birds distributing the seeds tend to frequent the outer parts of the tree's canopy. It is evident from the records submitted that, although *Viscum* grows on a wide range of hosts, distribution through this range is very uneven. Of the thirteen families involved, the Rosaceae alone account for nearly 70 per cent of the infested plants; and apple trees are the commonest hosts by far (42 per cent). Records of host-plants which are particularly worth noting include *Parrotia*, silver fir and, in view of its association with mistletoe at the festive season, holly. In spite of all that one reads about the attention paid by Druids to mistletoe growing on oak, only a single case of an infested oak has been reported. The present survey has produced some circumstantial evidence in support of the existence of 'strains' differing in the range of hosts they infest. More records will be needed before firm conclusions can be made about the validity or otherwise of these 'strains'.

New Zealand Forest Service: Report for 1954–55

THE annual report of the Forest Department of New Zealand, covering the period April 1954–March 1955 (pp. 103. Wellington: N.Z. Forest Service, 1955), commences by commenting on the remaining indigenous forests of the country which, after being completely ignored during the great exotic coniferous campaign of the earlier years of this century, have been receiving attention for some years. They are sylviculturally necessary as an insurance against widespread devastation of the exotic forests by disease or fire, in addition to being a source of invaluable specialist timber. A long-term objective for this indigenous forest is to bring as much as possible as soon as possible into a state of greatest productivity. Until recently, it was considered that conservation was best served by complete control of the indigenous cut. This has proved impracticable. The approach is now to be sylvicultural, and this is of considerable interest. The area is to be regenerated, artificially or naturally, with the main native forest timber species—the kauri, the podocarps and the beeches. Practice in Queensland, Australia, and research in New Zealand offer evidence that kauri can be artificially established as a productive crop. The good conifers have been subject to intensive study, and new management methods begun. The beech forest, so long neglected, shows great promise under management, and beech timbers are now widely used and respected. An interesting introduction is a Forest Biology Survey for the purpose of detecting population build-ups of any forest organism; thus outbreaks of insects or disease may be dealt with in their early stages.

Zoological Nomenclature

THE International Commission on Zoological Nomenclature will start to vote, as from February 24, 1957, on the following cases involving the possible use of its plenary powers, full details of which have already been published (*Bull. Zool. Nom.*, 12, Pts. 6–8; August 24, 1956): (1) *alligator* Blumenbach, 1779 (*Lacerta*), suppression, to protect *mississipiensis* Daudin [1801–1802], (*Crocodilus*) (cl. Reptilia); (2) *Campsicnemus* Haliday, 1851, validation (cl. Insecta, order Diptera); (3) *Elaphella* Bezzi, 1913, and *Lophiotherium* Gervais, 1850, validation (cl. Mammalia); (4) *verrucosa* Sars, 1901 (*Alona*), validation (cl. Crustacea, order Cladocera); (5) *Candona* Baird, [1846], designation of type species for and *Herpetocypris* (emend. of *Erpetocypris*) Brady and Norman, 1899, validation (cl. Crustacea, order Ostracoda); (6) *Conchoecia* (emend. of *Conchaecia*) Dana, 1849, validation of and designation of type species for (cl. Crustacea, order Ostracoda); (7) *Anchisauripus* Lull, 1904, and *Otouphepus* and *magnificus* (*Otouphepus*), both of Cushman, 1904, suppression (cl. Reptilia Theropoda [Ichnites]). Comments should be sent as soon as possible to the secretary to the Commission, Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

Folk-Lore

THE note in *Nature* of September 8, p. 522, on *Gwerin*, the new journal of folk-lore, ends with the sentence: "There is, indeed, room for a journal devoted to folk-lore, and all will wish the new venture every success". It has been pointed out to the Editors that this might give the impression that *Gwerin* is the only periodical devoted to folk-lore. This, of course, is not the case, for the periodical *Folk-Lore*, the quarterly journal of the Folk-Lore Society (c/o University College, Gower Street, London, W.C.1), has been in existence since 1878 and is still an excellent publication (often referred to in *Nature*) which deals with every aspect of folk-belief, tradition, custom and folk-lore research both in Great Britain and elsewhere.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: H. Bailey (agricultural officer, Gambia), agricultural officer, Northern Region, Nigeria; J. D. A. Harris (agricultural officer, Sierra Leone), senior agricultural officer, Western Region, Nigeria; H. P. Burgess (conservator of forests, Western Region, Nigeria), chief conservator of forests, Western Region, Nigeria; J. A. G. Ellis (assistant conservator of forests, Gold Coast), senior assistant conservator of forests, Gold Coast; M. T. Horwood (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; T. W. Hussey (senior assistant conservator of forests, Federation of Nigeria), conservator of forests, Federation of Nigeria; A. L. Roxburgh (assistant conservator of forests, Eastern Region, Nigeria), senior assistant conservator of forests, Eastern Region, Nigeria; G. J. Wiley (laboratory technologist, Department of Veterinary Services, Kenya), zoologist (entomology), Department of Veterinary Services, Kenya; F. Wilson (field officer, East Africa Trypanosomiasis Research Organization, East Africa High Commission), field officer, Veterinary Department, Uganda; Miss J. A. K. Abel (assistant statistician, Gold Coast), statistician, Gold Coast; E. C. Innerarity (statistician, Jamaica), senior statistician, Jamaica; P. S. L. Benton, specialist assistant, Agricultural Department, Northern Region, Nigeria; R. Briggs, agricultural officer, Somaliland; G. B. Cliff, C. A. Jackson and J. M. Suttie, agricultural officers, Kenya; I. R. Jensen, irrigation engineer, Agricultural Department, Northern Region, Nigeria; A. M. MacDonald, P. J. Myers and M. A. Owen, agricultural officers, Tanganyika; E. C. Patterson, agricultural officer, Aden; H. Rostron, agricultural officer, Nyasaland; C. B. Sykes, agricultural officer, Northern Region, Nigeria; M. J. van den Heuvel, pest infestation control officer, Produce Inspection Service, Northern Region, Nigeria; P. C. Kimber, assistant conservator of forests, Tanganyika; P. J. Sheldrake, assistant conservator of forests, Sierra Leone; R. H. Watson, assistant conservator of forests, Uganda; R. K. Evans, geologist, Nyasaland; E. Robinson, geologist, Jamaica; A. C. Hayward, process microbiologist, Colonial Microbiological Research Institute, Trinidad; E. C. Hislop, scientific officer (plant pathologist), Tanganyika; J. B. Roberts, scientific officer (organic chemist), Colonial Microbiological Research Institute, Trinidad; W. Bruce, veterinary research officer, Kenya; G. D. Paine, veterinary officer, British Guiana; P. H. S. White, veterinary officer, Northern Rhodesia.

Announcements

The Herbert Spencer Lecture for 1956 of the University of Oxford will be delivered by Sir Edward Bullard on December 4, at noon, his subject being "The Interior of the Earth".

Miss Mary George, principal information officer, Ministry of Agriculture, Fisheries and Food, has been appointed director and secretary of the Electrical Association for Women in succession to Dame Caroline Haslett.

Dr. Edward Wenk, jun., has been appointed chairman of the Department of Engineering Mechanics of the Southwest Research Institute, Texas. He is an authority in the fields of stress analysis, naval architecture and building design and construction, and was formerly head of the Structures Division of the David Taylor Model Basin, Washington, D.C.

Prof. G. P. Wright, Sir William Dunn professor of pathology in the University of London at Guy's Hospital Medical School, and Denis Hill, senior lecturer in clinical neurophysiology, Maudsley Hospital, London, and physician and lecturer in psychological medicine at King's College Hospital, London, have been appointed members of the Medical Research Council. The Earl of Limerick and Sir Geoffrey Vickers have been reappointed for a further term of office.

An international conference on rock magnetism, under the auspices of the International Council of Scientific Unions, will be held during November 1–3 in the Imperial College of Science and Technology, London, with Prof. P. M. S. Blackett as chairman. Those wishing to attend should write before October 18 to Dr. J. A. Clegg, Department of Physics, Imperial College, London, S.W.7.

The National Institute of Agricultural Botany is holding its Crop Conference for 1956 in Cambridge at the Union, Bridge Street, during December 12–13. The general theme will be "The Choice of Seed by Farmer and Grower", and sessions will be devoted to the seed testing service, vegetable crops, and wheats for the farmer to grow and sell. Further information can be obtained from the Secretary of the Institute at Huntingdon Road, Cambridge.

The French Society of Metallurgy is holding its annual "Journées Metallurgiques d'Automne" in the Maison de la Chimie, 28 rue Saint-Dominique, Paris 7e, during October 22–27. Further information can be obtained from the Société Française de Métallurgie, 25 rue de Clichy, Paris 9e.

The Fullers' Earth Union, Ltd., a member of the Laporte Group of Companies, has offered a scholarship to the Chemistry Department at the Imperial College of Science and Technology, London, to support and develop research in progress within the Department on the chemistry of clays. The studentship, which is of the value of £350 a year plus fees, is held in the first instance by Mr. G. S. Perry, who will study the intercalation of organic mixtures by clay minerals and the efficiency of such minerals in chromatographic separations.

The B.B.C. is presenting one or two research scholarships each year of £385 per annum to university graduates in electrical engineering or physics, to enable them to work for a higher degree at any university in the United Kingdom. The scholarships are for two years in the first instance, and are limited to male British subjects. The subject for research must be in fields of telecommunications or physics having an application to sound or television broadcasting. The Corporation has awarded one research scholarship only this year, to Mr. P. C. J. Hill (University of Birmingham), who will work in the Department of Electrical Engineering, Imperial College of Science and Technology, under the supervision of Dr. D. Gabor.

Reference was made in *Nature* of September 29 to the separate publication of Appendix III of the 1956 issue of the "Yearbook of the Universities of the Commonwealth". This appendix gives the number of overseas students in British university institutions. The corresponding Appendix III for the 1957 issue of the "Yearbook" has now been issued. This shows that for the academic year 1955–56 the total number was 9,723 (8,467 men, 1,256 women), as compared with 9,050 in 1954–55.

Erratum. In the review entitled "Techniques and Theory of Molecular Beams" by Dr. E. H. S. Burhop (*Nature*, **178**, 608; 1956), the name "Rutherford" should read "Retherford". We regret this error.

HIGH-TEMPERATURE RESEARCH

SYMPOSIUM AT THE UNIVERSITY OF CALIFORNIA, BERKELEY

A SYMPOSIUM on "High Temperature: a Tool for the Future" was held on the campus of the University of California, Berkeley, California, during June 25–27. This meeting was sponsored by the Stanford Research Institute and the University of California. Most of the 600 attending the symposium were from the United States; but other countries were also represented.

The subjects were dealt with in three major categories, one each day, namely: methods for reaching high temperatures, materials for containing high temperatures, and processes occurring at high temperatures. The chairmen for the three-day meeting, successively, were Dr. Nevin K. Hiester, of Stanford Research Institute, and Profs. Alan W. Searcy and Leo Brewer, of the University of California. To pinpoint the discussion further, each of the major divisions—methods, materials and processes—was divided into three areas for discussion by separate panels, a panel consisting of a leader and three others. Thus virtually every aspect of high-temperature research was discussed in thirty-six short papers and in the answers to questions from the floor, in addition to the luncheon address by Dr. Theodore von Kármán, chairman of the Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization, whose subject was "Aerodynamic Heating—the Temperature Barrier in Aeronautics".

The opening discussion of several practical methods of obtaining high temperatures by producing images of a heat source covered both optical and mirror furnaces in many different arrangements, employing arcs, flames and the Sun as sources. One of the most novel furnaces was described by Dr. Joseph M. McGreevy, head of the Optics and Nucleonics Branch, Material Laboratory, New York Naval Shipyard. He described a radiant panel consisting of specially developed, long lamps with closely wound tungsten filaments supported in quartz by molybdenum disks. He reported heating a specimen with such a bank of lamps at a rate of 27 cal./sq.cm./sec. with a rather uniform spatial distribution of the heating-rate.

Dr. McGreevy also described another method of heating by direct radiation. In this, oxygen and aluminium rod are fed into the furnace, in which a pool of molten aluminium floats on a lake of aluminium oxide previously formed during the run. Because of the movement of the aluminium pool, this has been termed the skating-sun furnace. Combustion takes place in the cloud of aluminium vapour just above the pool of aluminium, which provides an irradiance of nearly 20 cal./sq.cm./sec. near the furnace with a temperature of about 3,200° K.

Dr. Wolfgang Finkelnburg, of the Siemens-Schuckertwerke Research Laboratory, described the use of high-intensity electric arcs by which temperatures up to about 53,000° K. have been obtained.

Dr. Finkelnburg outlined the particle composition of gases at temperatures from about 2,000° K. to millions of degrees. Of considerable interest was his description of a supersonic plasma jet produced by expanding a water-vapour arc, burning under 50 atmospheres pressure, through a DeLaval nozzle along the axis of the anode.

Of great interest was the discussion by Dr. Heinz Fischer, of the Cambridge (Mass.) Research Center, of electrical discharges of short duration by which temperatures of 250,000° K. have been achieved. He also mentioned the work reported in the U.S.S.R. of reactions, employing similar techniques, to touch a million degrees K.

As a background for the discussion of materials of interest at elevated temperatures, Dr. John C. Fisher, of the General Electric Co., presented a comprehensive analysis of the various mechanisms for failure in metallic materials exposed to heat. He presented the idea that high-temperature failure due to cavitation fracture may be controllable by suppression of the intergranular sites at which nucleation of the cavities occurs.

Several speakers pointed out that ceramic materials often show a reasonable amount of ductility at temperatures near their melting points. In particular, Prof. Earl R. Parker, of the University of California, cited several experimental phenomena that indicate the possibility of producing ductile ceramic metals. He showed motion pictures of experiments in which cakes of ice treated with surface-active agents were bent 15° before failure. A better knowledge of the influence of surface conditions on mechanical behaviour may lead to the development of ductile ceramic materials.

Progress in development of strong thin ceramic coatings was outlined by S. W. Bradstreet, of the Armour Research Foundation. Among the more interesting new techniques is that of flame spraying, which deposits a cohesive layer of oxide on a metal with little heating of the surface.

Some processes already under investigation require the use of materials near the melting points of the most refractory solids. Prof. J. T. Norton, of the Massachusetts Institute of Technology, directed attention to the fundamental chemical factors which result in materials of very high melting points. He demonstrated that high-melting materials can be divided into two distinct classes. The first class is characterized by saturated electronic pair-bonding. It includes such materials as silicon carbide and aluminium nitride. The other class consists of compounds of certain transition elements with such non-metals as carbon, silicon and boron. Prof. Norton believes the predominant factor in producing this second class of materials is a filling of the *d* shells of the metal atoms. He suggested that boron phosphide might prove a useful refractory of the first class and that ternary compounds, such as Ta–C–Si compounds, might yield new high-melting materials of the second class.

Because the efficiency of all types of nuclear reactors can be increased by raising the operating temperatures, the importance of the effects of high-energy radiation and fission-product accumulation on high-temperature structural materials is obvious. Because present reactor designs involve rather moderate temperatures, almost no work has been done so far on the behaviour of materials at high temperatures in the presence of nuclear fission. There is some information on the effects of radiation on different types of materials at room temperature, however. This information was summarized by Dr. Clifford Weber, of the General Electric Company.

The effects of high pressures on the structure and properties of refractory materials were discussed by both Dean S. S. Kistler, of the University of Utah, and Dr. H. T. Hall, of Brigham Young University. Most startling of their comments was the fact that the melting point of certain refractories has been raised more than 1,000 deg. C. upon application of pressure. On the other hand, with substances that decrease in volume as they melt, the melting point is depressed by pressure. For example, germanium, under pressure, melts at a temperature 600 deg C. less than without pressure.

Although the details of the recently publicized successes in the manufacture of diamonds could not be disclosed, Dr. H. T. Hall, who was associated with that work, discussed some of its general aspects. In this he gave a striking example of the power of theoretical examination of high-temperature problems. He discussed a calculation demonstrating that known thermodynamic data for graphite and diamond and known kinetic data for conversion of diamond to graphite prove the impossibility of converting graphite to diamond in any temperature-pressure range achievable by conceivable means now possible for the investigation of phenomena that occur at pressures of 200,000 atmospheres and temperatures as high as 500° C.

Dean Kistler spoke of certain interesting resemblances of boron nitride to graphite. He directed attention to the fact that, from fundamental considerations, a cubic form of boron nitride with mechanical properties similar to diamond may be expected. The significance of such a possibility is obvious inasmuch as no known material has a hardness between that of boron carbide (2,700 Kroop K_{100}) and diamond (6,500). Dean Kistler held out the hope that a number of completely new materials may be formulated and produced, quite possibly with attractive high-temperature characteristics. As an example he remarked that a new form of silica has been produced simply by compressing quartz above 80,000 atmospheres. Cœsite was also mentioned by Hall as another modification of silica, produced by direct conversion from quartz heated to 2,000° C. at about 100,000 atmospheres pressure.

Dr. George Duvall and Dr. Milton C. Kells, of Stanford Research Institute, as well as Prof. B. H. Sage, of the California Institute of Technology, mentioned shock waves and high-speed nozzles as useful sources of high-temperature kinetic data. Reactions with half-times as low as five microseconds can be studied in shock tubes. A shock tube can yield a temperature of 11,000° K. in less than 12 μsec. High-temperature jets are being actively investigated as commercial sources of gases, such as acetylene.

Progress with the technique of melting and refining metals suspended in space by electromagnetic fields to avoid contamination with container walls was reported by I. E. Campbell, of the Battelle Memorial Institute, and J. C. R. Kelly, of the Westinghouse Electric Corporation. Kelly pointed out that the levitation-melting technique may also be useful for determining the surface tension of molten metals.

The Berkeley meeting made it clear that reactor and jet-engine development will continue to provide a tremendous impetus to research on high-temperature materials, and that high-temperature chemical processing is likely to witness spectacular expansion. It also demonstrated the comparative paucity of information in the high-temperature field. This was underlined by an example given by Kistler. He pointed out that, although silicon carbide is one of the oldest and best known synthetic high-temperature products, we still do not understand such things as the effects of furnace atmospheres on the rate of its formation, the factors determining whether the cubic or hexagonal form of the compound will be produced, or the effects of impurities on such important properties as conductivity, oxidation resistance, and grinding characteristics. Clearly, much remains to be done.

The papers given by the members of the various panels, with answers to the many questions put from the floor, are being printed and are expected to be issued about October 30; copies will be available from the Public Relations Department, Stanford Research Institute, Menlo Park, California (price 5 dollars each).

CHROMOSOME PROBLEMS

A CONFERENCE on chromosomes was held in the Landbouwhogeschool, Wageningen, Holland, during April 16–19, Profs. H. J. C. Tendeloo and R. Prakken being chairman and secretary respectively. The programme consisted of seven lectures with discussions.

Prof. E. Heitz (Tubingen) spoke first on chromosome structure in the nucleus, during mitosis and meiosis.

There are five different types of structural elements recognized in a chromosome: the spiral, the chromomeres, the centromere (primary constriction, kinetochore), the secondary constrictions (SAT-zones) and the heterochromatine. Four of these are directly (heterochromatin) or indirectly (the spiral, the centromere, the SAT-zones) demonstrable in the nucleus. These serve as proof of the individuality of the chromosomes within the nucleus.

The essential element of every chromosome, the spiral, which is tightly coiled during metaphase and anaphase, uncoils during telophase and gives rise, after the calymma has disappeared, to the thread-like structure of the nucleus. This structure has been observed in the living state and can also be demonstrated in the nucleus after fixation.

Often, certain parts of chromosomes do not uncoil during telophase and probably do not lose their calymmatic substance. Since such heterochromatic pieces occupy defined positions within the chromosomes, they can be recognized as more or less compact and highly coloured pieces in their respective positions.

Since rather large pieces of the chromosome on both sides of the centromere are often heterochromatic, the position of the centromere can be demonstrated in the proximal part of the young nucleus.

Chromomeres themselves (that is, compact, small and nucleal positive pieces within the anucleal uncoiled zygotene or pachytene chromosome-fibres seen during meiosis) cannot be demonstrated in the somatic nucleus, although heterochromatic pieces may be mistaken for them.

Secondary constrictions can be recognized in the nuclei by means of their function. They condense the nucleoli during telophase. Since the number and position of every secondary constriction are definite, the number and position of the nucleoli, in the young nuclei at least, correspond to the number and position of the secondary constrictions.

There are many indications that the major spiral contains a minor spiral. Furthermore, there are many reasons to suspect the existence of a third, perhaps molecular, spiral, running in the minor spiral, for example, the enormous length of the fibrils in the giant Dipteran chromosomes may thus be explained.

In addition, there are many indications that during anaphase there are already present two daughter spirals, at least. Electron-microscopic studies have shown that a sub-light-microscopical spiral is probably the basic element of every chromosome. If so, the known spiral should be composed of a bundle of different ultraspirals. Nevertheless, it is premature to seek a connexion between the proposed helical structure of deoxyribonucleic acid and the chromosome spiral.

Prof. H. D. Springall (University College of North Staffordshire) discussed the chemical structure of proteins and nucleic acids.

The study of an organic natural product follows the pattern: (1) isolation; (2) proof of purity; (3) estimation of molecular weight, and, if a macromolecule, molecular size and shape; (4) analysis; (5) degradation; (6) synthesis; (7) if a macromolecule, study of the configuration of structural elements within the molecule.

The application of this sequence of studies to proteins and nucleic acids is very difficult because of their very high molecular weights, and their fragility and intractability. The methods devised were briefly discussed and the results summarized.

(1) *Proteins.* These consist fundamentally of polypeptide chains of α-amino-acid residues (of about 19 different kinds). These chains are helical, most of them probably related to the 3·6 residue helix of Pauling. The helical chains are disposed in linear patterns in the fibrous proteins, and are folded into compact globular molecular shapes in the more soluble globular proteins.

The penetration of modern methods into protein structure is indicated by the analytical and degradative work which has established the complete structural framework of insulin (Sanger) and the complete synthesis of the nonapeptide amide hormones, oxytocin and vasopressin (du Vigneaud).

(2) *Nucleic Acids.* The building units of these are a few purine and pyrimidine N-bases; the sugars, ribose or deoxyribose (giving rise to ribo- or deoxyribo-nucleic acids); and phosphoric acid. There are many theoretically possible modes of assembly of these diverse and polyfunctional components. The natural scheme involves the linkage (*a*) (β-glycosidic) of an N-base to a sugar (to give a nucleoside), (*b*) (ester) of phosphoric acid to the sugar component of a nucleoside (to give a nucleotide) and (*c*) of nucleotides by phosphate diester formation via the 3′- and 5′-sugar positions. The polynucleotide chains in deoxyribonucleic acid are arranged in twin helices about a dyad axis (Watson–Crick). The arrangement in ribonucleic acid is not known.

Synthetic work on nucleic acids is of extreme difficulty and has not yet gone beyond dinucleotides (Todd).

(3) *Nucleoproteins.* The general structure of these substances, especially the viruses, was briefly considered.

Prof. T. Caspersson (Stockholm) spoke on the cytochemistry of the nuclear elements.

The lecture gave a summary of the early cytochemical studies of the metabolism of the cell nucleus, mainly carried through by aid of ultra-violet ultramicrospectroscopy. The central point had been the study of the role of the polynucleotides. Especial attention was given to the conspicuous changes in the protein content of various nuclear structures during mitosis and during the interphase, the functional stage of the cell.

In the latter part of the lecture it was pointed out that at a certain stage these studies were virtually entirely blocked by a series of technical difficulties, mainly arising when dealing with the protein components. This situation led to a comprehensive investigation aiming at development of the methods in different directions. Very recently major advances in this field have been reported and thus the cytochemical problems concerned in cell nuclear metabolism can now be attacked in a novel and hitherto inaccessible way. The technical procedures were not presented in any detail as very few data on chromosomes, gained with the new techniques, are, as yet, available. These are discussed, for example, in Cold Spring Harbor Symposia in Quantitative Biology, 1956.

Mr. N. W. Pirie (Rothamsted) dealt with the recognition, distribution, and action of nucleic acids.

There is no unequivocal way to recognize nucleic acid that has not been isolated. Methods depending on the determination of phosphorus extracted by different procedures can be confused by other phosphorus compounds; methods depending on the precipitation of the bases and determination of nitrogen are even more fallible; methods depending on the determination of ultra-violet absorption can be misleading both because of the presence of other substances with a similar absorption spectrum (for example, ascorbic acid) and also because of the effects of orientation. Feulgen staining for aldehydes is a more trustworthy method of recognizing deoxyribonucleic acid than any of the methods for ribonucleic acid; but here, too, there are difficulties.

The use of nuclease preparations increases the precision of these determinations; but their value depends on the demonstration, rather than the assumption, that the preparation is free from other relevant enzymes. Lack of action can be due to inaccessibility of the nucleic acid or to the presence of inhibitors. There is little evidence for the occurrence of free nucleic acid; but the nature of the linkage to proteins and other materials is obscure and probably diverse. This fact need not complicate histochemistry, because the techniques of fixation generally denature the protein and liberate any bound nucleic acid; but it complicates attempts to interpret the mode of action of nucleic acid, for the acid may be an artefact. There is some evidence for changes analogous to denaturation in nucleic acids; if such a phenomenon exists it extends still more widely the already ample possibilities for isomerism and specificity.

Deoxyribonucleic acid tends to be confined to the nucleus but is often found elsewhere, for example, egg-white and viruses, and may not have been looked for carefully. Ribonucleic acid is present nearly everywhere in organisms though it is often concentrated in regions such as microsomes and the bacterial cell wall. Not all deoxyribonucleic acid is present as genes: What is the status of the common generalization that all genes are deoxyribonucleic acid? *A priori* this seems unlikely. Similarly, regions of high metabolic activity are often rich in ribonucleic acid: Are regions of protein synthesis characteristically richer still? It is surprising that there seems to be so little deoxyribonucleic acid–ribonucleic acid interconversion, and that actions such as the stimulation of polysaccharide and enzyme synthesis have been found so seldom.

Prof. A. Gustafsson (Stockholm) spoke on regularities and intentional control of mutation processes in plants.

From comparative experiments on barley, using X-rays, neutrons and specific chemical compounds as mutation-inducing agents, Gustafsson and his collaborators conclude that chromosome breakage and consequent X_1 sterility can be induced in barley by certain specific compounds: (1) without visible mutations of the chlorophyll apparatus, for example, 8-ethoxycaffein, (2) probably with such mutations, for example, ethylene oxide and mustards. Some agents, for example, nebularine, do not cause chromosome breakage, rearrangements, or X_1 sterility, but may increase mutation-rates considerably and cause fundamental changes in the mutation spectrum.

Chromosome breaks induced by strongly ionizing neutrons do not differ from those induced by X-rays. Random breaks, re-attached to form translocations, rarely produce noticeable changes in morphology, anatomy or ecology, but such translocations are highly instrumental in the genetical isolation of plant populations.

Plant-breeding in its genetical aspects rests on a profound knowledge of genes and chromosomes, the importance of heterochromatin and euchromatin, chromosome number, heterozygosity, gene recombination and mutation control. Mutations, whether spontaneous or induced, are generally regarded as arising at random. Gustafsson feels that this is not so. The mutation spectrum varies with the type of species and mutagenic agent used. The time does not seem far off when we shall be able to induce chromosome rearrangements and gene changes independently from one another, and control or direct the mutation process so that mutations of distinct loci, including those of high-productivity effects, are intentionally produced.

Prof. A. Müntzing (Lund) discussed chromosomes in relation to species differentiation and plant breeding.

Some species, although morphologically indistinguishable from one another, are isolated reproductively. Lewis's work on *Clarkia* has shown how a study of the differentiation of populations within a species can lead to an understanding of the mechanism of speciation in that group, and the part played by chromosome re-arrangements at the intra- and inter-specific levels. The salivary gland chromosomes of *Drosophila* have provided a means by which the nature of this chromosome differentiation can be studied in detail. In only a few cases has it been adequately demonstrated that the difference between two species is genic only and that chromosomal rearrangements have not occurred. Change in chromosome number to give an aneuploid series may result from fusion or breakage of chromosomes with diffuse centromeres.

Prof. Müntzing also spoke of the part played by polyploids in plant breeding and the value such plants had. Cytological analysis had shown the origin of many polyploid cultivated species and how they could be resynthesized, so that fresh genetic material could be incorporated into existing varieties. New polyploids have also been made and found to be of value in plants such as rye, clover, turnips and fruit trees. By the use of wheat plants lacking a pair of homologous chromosomes (nullisomics) it has been possible to determine on which chromosome various genetic factors are situated and also to transfer whole chromosomes, bearing genes for disease resistance, to other varieties.

Prof. C. D. Darlington (Oxford) discussed the means of communication in the cell. These are to be inferred from chemical, genetical and radiation experiments and from comparative developmental studies. The co-operation and competition of nuclei had been revealed by classical experiments the meaning of which was now becoming clear in genetic and chemical terms.

The co-operation of gene activities and the co-ordination of chromosome movements both required communication along the chromosomes themselves. Evidence in relation to nucleoli, heterochromatin, and especially centromeres, showed that this communication was sometimes canalized along the chromosomes, a property which was variable and physiologically controlled. The inference of position effects from breeding experiments could thus be greatly extended. Further gene activity and integration could be seen as conditional not only on the local character of the cytoplasm but also on its cyclical changes. These cyclical changes in turn were co-ordinated in two normal systems (mitosis and meiosis) in every species. The relations of these normal systems were made clear by the abnormal systems which have now been described in many species and could be provisionally interpreted in terms of deoxyribonucleic acid and protein relations. With these cytological inferences the main concepts of genetics and embryology were consistent but they appeared in a new and larger perspective.

The author is indebted to Prof. C. D. Darlington (Oxford) and to Mr. K. M. Goodway (University College of North Staffordshire) for assistance in the preparation of this account. H. D. SPRINGALL

BRITISH WELDING RESEARCH ASSOCIATION

OPEN DAY AT THE ABINGTON LABORATORY

IN our present society, which is committed to the pursuit of technology in support of a material standard of life, research associations and similar bodies form an essential communication between fundamental science and industry. This theme was developed by the Minister of Supply, Mr. R. Maudling, when proposing the toast of the British Welding Research Association at the annual luncheon and open day held at the Association's laboratory at Abington, Cambridge, on July 24. The Minister went on to encourage the production of memoranda containing the essence of sound practice supported by scientific investigation, the commencement of which in the case of the Association in fields such as brazing and the construction of arc-welded machinery has been made possible by application of Foreign Operations Administration funds from the United States. In the ensuing replies the work of Sir William Larke, spanning from the inception in 1936 of the Welding Research Council on through the formative years of the Association, was warmly acknowledged on the occasion of his retirement as president.

As in former years, an exhibition of work in progress was arranged. Illustrative examples of current metallurgical work were housed in the partly completed new laboratory, since the metallurgical staff is being transferred from Park Crescent, London, to Abington this autumn.

Success in the production of strong and ductile fusion welds in high-strength aluminium alloys by means of the tungsten-arc process depends strongly upon the provision of filler material of correct composition when diluted with parent material. Performance with different compositions may be shown by means of a cracking test, in which shrinkage restraint is varied along a butt weld by means of symmetrical slots of graded length transversely cut into the parent plate at intervals along the weld. The test plate thus has the appearance of a fishbone, and with unsatisfactory conditions longitudinal weld-cracking occurs in the region of greatest restraint. The fusion welding of cylindrical fatigue specimens with the use of filler rods developed in this way was demonstrated.

In the case of the self-adjusting arc process, the arc is struck between the end of the filler rod and the plate, and the rod is advanced at a fixed speed to neutralize its own fusion. This process, although markedly successful by virtue of the results achieved and the simplicity of the control equipment, leads to some limitation in the ranges of voltage and current which may be successfully used, irrespective of the diameter of the filler wire through which the current is passed. Investigations undertaken co-operatively by the Electrical Research Association and the British Welding Research Association have shown experimentally that there are three different characteristics of arc operation and metal transfer, depending upon arc voltage. Thus, at low voltages discrete droplet transfer leads to irregular metal deposits unsuitable for welding. Above this voltage, in the practical working range, a spray transfer operates. At even higher voltages the spray transfer is accompanied by such high metal velocities that a strongly scouring action occurs in the molten pool, and unwanted complete penetration of the plate may take place. Nevertheless, in the working range, the somewhat lower spray-transfer velocity may be put to good use when welding in positions other than the horizontal. From the point of view of arc characteristics, the change from droplet to spray transfer is interesting because of the sudden change of current accompanying it.

The use of carbon dioxide as a shielding gas for arc welding of ferrous materials is of much topical interest, and typical welds made with this process were on view. In the case of other welds made with a mixture of argon and oxygen as shielding gas, unwanted porosity has been found and is thought to be associated with a reaction between carbon in the steel and gas which is either trapped or dissolved. Such porosity ought to be avoidable with sufficient added silicon in relation to carbon present in the fused metal. The manner of estimation of the requisite silicon content of the filler material was demonstrated.

Successful welding of metals such as titanium and zirconium is dependent upon the exclusion of reacting gases such as oxygen and nitrogen, for which these metals have great affinity. Welds of high quality for standardization purposes may be made in a completely closed argon chamber. In the apparatus which was shown, a sufficient degree of purity of the arc atmosphere is ensured by the production of high vacuum before flooding with argon.

Although it would be undesirable to claim that metallic titanium had not previously been cut successfully with an oxygen jet, predictions of feasibility were made by a member of staff of the Association as a result of earlier fundamental work on combustion in gas cutting. This was strikingly confirmed by experiment, and expectations of a high optimum cutting-speed, five times that for steel, were realized. Surface embrittlement, which was expected to arise from gas contamination, was not found to be as serious as anticipated, probably because of the high speeds. A practical demonstration of such cutting on moderately heavy sections was witnessed by visitors.

With regard to engineering activities, a further building frame was on view, after test to the point of plastic collapse by investigators under Prof. J. F. Baker, from the Department of Engineering in the University of Cambridge. This particular frame contained two stories, and illustrates the progress which has been made in bringing more complex constructions within the scope of load calculations for plastic collapse. The Association has gained much benefit from its financial support of this work.

Experimental stress analysis of elements of welded pressure vessels continues to fulfil an industrial requirement. The very thick pressure vessel containing circular nozzle openings, a model of which was shown last year, is shortly to be installed. The addition of reinforcement to reduce stress concentrations at its openings has been demonstrated theoretically to be unnecessary, and economy would ensue if this could be proved experimentally. At the opposite extreme, accumulated theory suggests that reinforcement may have to be substantial for large circular openings which are likely to be in use in thermal reactor vessels, because of the low ratio of shell thickness to diameter in such cases.

Stress analysis of vessels with openings has also been supplemented by pulsating pressure fatigue tests, from which the former work has been well vindicated. Fracture in some of the cases shown was directly associated with the calculable stress concentrations due to the openings themselves, rather than to unpredictable local stress concentrations induced through sharp changes of section at weld profiles.

In the fatigue laboratory, further results were presented from tests of high-quality butt welds in mild steel made by various welding processes. Recent work has also been addressed to a definition of the influence on fatigue strengths of various weld faults. Although, in the case of pipe butt welds, reductions of strength from all faults may be observed, the overriding effects of cracking and lack of penetration have been readily demonstrated. In comparison, the influence of moderate amounts of totally enclosed porosity appears to be reasonably small.

Determination of the fatigue resistance of all but the smallest welded shafts may be extremely slow if it is necessary to use a rotating-bending testing machine. In this respect, a resonance machine with a single unbalanced rotating mass, co-axial with the fixed shaft, enables an increased speed of testing to be used, with the same stress cycle and a reasonably small power-input. It is later hoped to build an apparatus of greater load capacity than that which was on view.

In the pulsating pressure fatigue testing of welded joints in thick steel tubes, fluid pressures of many tons per square inch must be applied. A machine for this purpose, developed at the University of Bristol, was shown in use. A characteristic of the machine is the reduction of fluid volume to the greatest possible extent, whereby the energy stored at each pulsation may be reduced to low values.

Although the use of ultrasonic inspection for weld flaws may increase markedly in future thick welded constructions, it has first been necessary to achieve reliable calibration with regard to the strength of echoes. In this respect, the use of standard reference blocks was demonstrated, by means of which an apparatus may be quickly calibrated. Equal attention is now being given to attenuation of pulses by virtue of different surface contours in contact with the ultrasonic probes, in conjunction with various fluid coupling agents.

During the past year, experimental work on the brittle-fracture strengths of welded mild-steel plates has been continued with the 700-ton tension test rig, which was on view together with the fractured specimens. It is now believed that the role of residual stress in promoting fracture is better understood. While these stresses have no embrittling influence of themselves, it has been shown in the presence of a notched weld parallel to the direction of tension, and notch brittle parent material, that the static strengths of wide plates may be reduced to low values, such as are normally present in structures. When the residual stresses are removed, yield point stresses may be consistently sustained before fracture takes place. Thus, it is now believed that the beneficial effect of stress-relieving of welded structures may be more readily assessed.

UNIVERSITY AFFAIRS IN GREAT BRITAIN, 1954–55

CONTRARY to the past few years, the "Returns from Universities and University Colleges in receipt of Treasury Grant for the Academic Year 1954–55", issued by the University Grants Committee*, show an increase of 1,103 in the number of full-time students; the latest figure is 81,705, compared with 80,602 in 1953–54, 81,474 in 1952–53 and 83,458 in 1951–52, and it is expected that the numbers in 1955–56 will show a further and greater increase, as it is known that there were 3,378 more full-time students in the autumn term of 1955 than in that of 1954. In the English universities, full-time men students increased by 395 and women by 500; for Wales, the corresponding figures were 46 and 17; and for Scotland, 61 and 84. There were 4,987 full-time and 2,010 part-time students from overseas within the British Commonwealth and 3,617 full-time and 1,594 part-time students from foreign countries; for 1953–54 the corresponding figures were 4,607 and 1,819 for the Commonwealth and 3,373 and 1,379 for foreign countries. There was no significant change in the distribution of full-time students among the faculties; but there were small increases both for science and technology: from 21·1 to 21·2 per cent for the former, an increase from 16,971 to 17,327, and from 12·4 to 12·9 per cent for the latter, an increase from 10,036 to 10,586. Full-time advanced students of pure science increased by 45 to 3,335, those of technology by 74 to 1,455, of agriculture by 17 to 307, and of veterinary science by 6 to 18, while those of medicine decreased by 49 to 813. Of the full-time advanced students, 2,835 (or 23·2 per cent) were working for the teacher's diploma. Of the full-time students, 64,778 were reading for a first degree, 4,099 for a first diploma and 12,212 were engaged in research or other advanced work, the corresponding figures for 1953–54 being 63,560, 4,350 and 12,166.

The proportion of assisted students was 72·9 per cent compared with 71·9 per cent in 1953–54; for England as a whole it increased from 74·2 to 74·9 per cent, but for Scotland it increased from 56·8 to 59·5 per cent, and for Wales decreased from 88·5 to 86·6 per cent. The dependence on parliamentary grants was practically unchanged, the £25,059,434 received from this source representing 70·4 per cent of the total income compared with 70·5 per cent in 1953–54. Of the recurrent income, 10·7 per cent came from fees, 4·1 per cent from endowments, 3·2 per cent from local authority grants and 1·1 per cent from donations and subscriptions, the corresponding figures for 1953–54 being 12·0, 4·3, 3·6 and 1·6 per cent, respectively. Universities were asked to show separately for the first time in 1954–55 income from grants for research and income receivable under research contracts: for England the former amounted to £1,079,307 and the latter to £685,615; for Wales the corresponding figures are £17,787 and £8,213, and for Scotland £115,308 and £45,683. The ratio of staff to students again improved, the full-time teaching staff being now 9,810, compared with 9,514 in 1953–54. The distribution of this increase among staff is: professors, 43; readers, assistant professors and independent lecturers, 36; senior lecturers, 41; and lecturers, 176.

Of the full-time students, 63,068 were in England (15,121 at Oxford and Cambridge, 18,201 at London and 29,746 at other universities and university colleges), 4,494 in Wales and 14,143 in Scotland. Except at Liverpool and at Reading, where there were decreases of 1 and 10, respectively, the increase in students was distributed over all the universities and colleges, but only at Oxford (150), Southampton (137), Durham (139), Leeds (128), St. Andrews (114) and Cambridge (104) did the increase exceed a hundred, though the increase by 95 to 719 at the Manchester College of Technology was the highest proportionate increase. The proportion of full-time students residing in colleges and halls of residence increased to 28·4 per cent; and, of these 23,243 students, 8,262 were at Oxford and Cambridge, 11,838 at other English institutions and only 1,261 in Wales and 1,882 in Scotland. The proportion of men in residence was 24·2 per cent, and of women 41·3 per cent, while 34,548 students (42·3 per cent) were in lodgings and 23,914 (29·3 per cent) at home, compared with 40·9 per cent and 31·0 per cent, respectively, during the previous year. Of the 22,463 students admitted for the first time during 1954–55 (an increase of 1,310 on 1953–54), 20,946 were reading for a first degree and 1,517 for a first diploma; of those reading for a first degree, 1,233 were under eighteen years of age and 11,843 were nineteen or more. Of the full-time students, 35,723 out of 47,793 men and 11,528 out of 15,275 women in England were receiving assistance by way of scholarships, exhibitions or other awards from public or private funds; for Wales the corresponding figures are 2,726 out of 3,187 men and 1,166 out of 1,307 women; and for Scotland, 6,331 out of 10,315 men and 2,089 out of 3,828 women. Of the 61,295 full-time men students, 36·1 per cent were in arts, 22·3 per cent in pure science, 16·6 per cent in medicine and 17·0 per cent in technology; for the 20,410 women students the corresponding figures are 63·7, 18·0, 14·4 and 0·7 per cent, respectively. Medicine and dentistry claimed 52·2 per cent of the part-time advanced students, arts 34·9 per cent, pure science 9·2 per cent and technology 2·7 per cent, compared with 49·6, 35·6, 9·3 and 4·8 per cent, respectively, during 1953–54.

---

* Universities Grants Committee. Returns from Universities and University Colleges in Receipt of Treasury Grant for the Academic Year 1954–1955. (Cmd. 9800.) Pp. 50. (London: H.M.S.O., 1956.) 2*s.* 9*d.*

The recurrent income of the universities and university colleges of Great Britain increased by £4,488,054 to £35,600,078, of which £25,059,434 was from parliamentary grants, £3,815,306 from fees, £1,448,212 from endowments, £1,140,643 from local authority grants and £401,379 from donations and subscriptions. Of the total income of £26,200,007 from public funds and £9,400,001 from other sources, the University of London received £7,803,937 and £2,748,652, respectively, while the figures for other universities were Cambridge £1,659,067 and £1,371,494; Oxford, £1,489,853 and £780,791; Manchester, £1,293,893 and £321,976; Leeds, £1,107,057 and £350,586; Birmingham, £1,069,933 and £438,788; Durham, £1,152,240 and £369,320; Liverpool, £1,057,395 and £320,826; Bristol, £825,567 and £430,386; Sheffield, £710,398 and £186,487; Nottingham, £568,488 and £148,410; and Reading, £624,686 and £93,438. No other English university or university college had an income exceeding half a million pounds; but for the four universities in Scotland the incomes from public funds and from other sources were Aberdeen, £576,117 and £138,690; Edinburgh, £1,235,533 and £415,402; Glasgow, £1,229,990 and £397,244; and St. Andrews £612,090 and £129,357. The University of Wales, including the Welsh National School of Medicine, received £1,326,200 and £336,405.

Of the recurrent expenditure of £34,791,656, an increase of 15 per cent on 1953–54, administration accounted for 7·2 per cent, departmental maintenance 69·3 per cent, maintenance of premises 12·0 per cent, and miscellaneous expenditure 10·2 per cent. Departmental maintenance, which includes salaries of teaching staff, payments for superannuation, the running costs of laboratories, lecture rooms, libraries and museums, and the supply of books, specimens, materials, apparatus, etc., increased by £2,095,004 to £24,100,985 and expenditure on maintenance of buildings increased by 8·2 per cent. Salaries and superannuation amounted to £15,958,695, compared with £13,616,426 in 1953–54, the increase being 17·2 per cent for teaching staff and 14·8 per cent for technicians and laboratory assistants.

Library expenditure, excluding general maintenance of library buildings, rates, heat, light, repairs, etc., amounted to £1,352,244, or 3·8 per cent of the total expenditure, compared with 4·0 per cent in 1953–54 and 3·9 per cent in 1952–53. Of this total, £707,236 was for salaries and wages, £154,963 on periodicals and £101,885 on bindings. Of the £310,102 expended on books, £72,939 was in the schools and colleges of the University of London, including £12,192 at the Central Library, £6,183 at the London School of Economics, £9,273 at University College, £5,153 at the School of Oriental and African Studies and £4,909 at Bedford College. The University of Oxford spent £31,585 on books; Cambridge, £22,796; Manchester, £21,559; Liverpool, £11,608; Leeds, £10,116; Durham, £12,993; Birmingham, £10,215; and Bristol, £9,553. Only the Universities of London (£44,813), Oxford (£14,948) and Cambridge (£12,233) spent more than £10,000 on periodicals, and only Birmingham (£7,200), Leeds (£5,855) and Manchester (£6,458) more than £5,000. The University of Wales spent £14,789 on books and £8,457 on periodicals. In Scotland, Edinburgh spent £15,087 on books and £6,813 on periodicals; Glasgow, £11,662 and £7,382; St. Andrews, £11,856 and £4,702; and Aberdeen, £8,333 and £3,954.

INSTITUTE OF PHYSICS

REPORT FOR 1955

The thirty-sixth annual report of the Board of the Institute of Physics*, which was presented to the annual meeting of the Institute in London on July 16, indicates the growing importance of the work of the Institute and the increasing number of physicists now being employed in industry, teaching and research. The total membership rose during the year under review by 397 to 5,146, reaching the five thousand mark for the first time. There were increases in all the grades of membership, with substantial increases in the associateship and graduateship grades. 726 applications for election or transfer to the various grades were received during the year, compared with 579 during 1954. Eleven of the fifty-four candidates who took the examination for graduateship of the Institute were successful. The numbers of candidates for the final examinations for the National Certificate in Applied Physics were 309 for the ordinary level and 82 for the higher, compared with 206 and 75, respectively, in 1954.

The report mentions that representatives of the membership committee visited seven technical colleges which had applied for official recognition, or extension of recognition, by the Board as institutions suitable for training of physicists in accordance with the Institute's membership regulations. The degrees of the University of Malaya were also recognized by the Board. The report of an inquiry by the Board into the availability of places for students of physics in the universities and larger technical colleges of Great Britain was published by the Institute in its September *Bulletin*, and reprints have since been widely circulated. Many requests continue to be received from those leaving school and others concerning careers in physics, and the deputy secretary of the Institute, Mr. N. Clarke, has addressed meetings on this subject in Aberdeen, Bristol, Edinburgh, Ewell, Glasgow and Swansea. The Institute has kept in close and constant touch with the permanent officers of the American Institute of Physics and has made a joint inquiry with the Physical Society, London, about the likely demand for English translations of Russian papers on pure and applied physics.

---

* Thirty-sixth Annual Report of the Board of the Institute of Physics, 1955. Pp. 18. (London: Institute of Physics, 1956.)

The need for a recognized permanent body in Great Britain before which papers on the application of nuclear energy and ancillary subjects could be read and discussed was the subject of negotiations initiated by the major engineering institutions, and as a result a body known as the British Nuclear Energy Conference was formally inaugurated at a meeting in London on November 30. The Institute of Physics and the Institutions of Civil, Mechanical, Electrical and Chemical Engineers are the founding constituent bodies, and each has three representatives on the governing board.

Details of the various activities of the nine branches and seven specialist subject groups of the Institute are briefly referred to in the report. There are eight local branches in Great Britain, and also an autonomous Australian Branch, under the presidency of Prof. L. G. H. Huxley, with divisions in the different States. During November 22–24 an exhibition of scientific instruments and apparatus was held by the Australian Branch and was well attended. The Liverpool and North Wales Branch held its inaugural meeting on May 19, 1955, in the Department of Electrical Engineering of the University of Liverpool, and the inaugural lecture was delivered by Prof. Z. Kopal, professor of astronomy in the University of Manchester, who took as his subject "The Physics of the Sun" (published in *Brit. J. App. Phys.*, **7**, 119; April 1956). The Scottish Branch, in addition to holding meetings in Glasgow, Edinburgh, Aberdeen and Dundee, arranged a course of five lectures on computers, and a conference on the training of physicists for industry was held by the Yorkshire Branch at the Rotherham Technical College on April 21. The two main subjects for discussion at the annual conference of the Education Group during April 14–15 were the teaching of thermodynamics and the place of physics in a liberal education; the Electronics Group held a symposium on recent developments in magnetic materials, and the X-ray Analysis Group has continued its work, under the direction of Prof. A. J. C. Wilson (University College, Cardiff), on the provision of data for the index of diffraction patterns which is published by the American Society for Testing Materials.

Both the circulation and the advertisement revenue of the Institute's two monthly periodicals, the *Journal of Scientific Instruments* and the *British Journal of Applied Physics*, increased satisfactorily during the year; unfortunately, costs of production continued to rise. The amount of material submitted and published in 1955 was similar to that in 1954; but as more papers were published than accepted, the average delay between submission and publication of acceptable manuscripts was reduced slightly. The fourth supplement to the *British Journal of Applied Physics*, containing the proceedings of the Electronics Group's symposium held in Cambridge, 1954, on luminescence with particular reference to inorganic phosphors, was published as part of the 1955 volume. The twelve monthly issues of the Institute's *Bulletin* (issued to members only) contained fourteen articles, some of them invited contributions and others based on lectures given to the Education Group. The *Bulletin* is appearing in a new and improved form this year. In the "Physics in Industry" series, two new volumes—"X-ray Diffraction by Polycrystalline Materials" containing contributions by thirty-one members of the X-ray Analysis Group, and "Physics of Fibres" by H. J. Woods—were published during the year, and three booklets in the "Student Monograph" series were issued.

At the general meeting of the Institute the following were elected to take office on October 1: *President*, Mr. O. W. Humphreys; *Vice-President*, Dr. B. P. Dudding; *Honorary Treasurer*, Dr. J. Taylor; *Honorary Secretary*, Prof. F. A. Vick; *New Ordinary Members of the Board*, Dr. L. R. G. Treloar and Mr. G. W. Warren. Sir George Thomson, master of Corpus Christi College, Cambridge, was elected to honorary fellowship in recognition of his outstanding contributions to physics and his services to physicists.

HIGH CLOUD OVER SOUTHERN ENGLAND

A SUBSIDIARY task of the Air Ministry Meteorological Research Flight is the making of observations of cirrus clouds, the white ice-crystal clouds, called popularly 'mare's tails' in one form, which are the highest clouds ordinarily visible. The rarely seen mother-of-pearl and noctilucent clouds are much higher. R. J. Murgatroyd, chief meteorological officer of the Flight, discusses these observations in Professional Note 119 of the Meteorological Office*.

Cirrus clouds are not easily studied in flying through them, because often they are so tenuous that the observer finds it hard to tell when he has reached a cirrus cloud clearly seen from far below. The tops, however, are more sharply defined than the bases. It was found that cirrus cloud is almost always entirely within the troposphere, though the tops are often only just below the tropopause. On a few occasions reported in the note, 'cloud' was seen in the stratosphere; but it is known that the observations in July and August 1953, which constitute the majority, were actually of volcanic dust produced by an eruption in Alaska on July 7. The heights of the tops were usually within 2,000 ft. of the tropopause, and the lower the tropopause the closer the cirrus tops were to it. Cirrus, which looks so thin from the ground, is usually between 3,000 and 5,000 ft. thick, and may be as much as 12,000 ft. thick.

An important feature when cirrus clouds were visible was a moist layer extending downwind from them at the same level, which became more pronounced (depression of frost point below dry bulb decreasing) as the clouds were approached. The humidity in the clouds seems to be surprisingly low. The depression of the frost point ranged from 12 to −2 deg. F., with a mean depression of about 3 deg. F. This average value corresponds to about 80 per cent relative humidity with respect to ice and, since the saturation vapour pressure is higher over water than ice, a markedly lower one (50 per cent) with respect to water, which is remarkable if it is correct that saturation with respect to water is necessary for the formation of cirrus cloud. The presence or absence of cirrus is a useful guide to the fighter pilot as to whether his aircraft is likely to produce a marked condensation trail, as it was found that, when cirrus was present, the probability of making a very persistent condensation trail was roughly about twelve times (60 per cent of flights) the probability (only 5 per cent of flights) when it was not.

CRETACEOUS AMMONITES OF WEST AFRICA

CRETACEOUS ammonites have long been known from many parts of West Africa, and some of the faunas, notably those of Angola, have been the subject of substantial works. Apart, however, from descriptions of Turonian and Coniacian faunas from the Mungo River, comparatively little has been published about the Cretaceous ammonites of Nigeria. With the publication, however, of Dr. R. A. Reyment's "Cretaceous Ammonoidea of Southern Nigeria and the Southern Cameroons"*, we have for the first time a comprehensive monograph of the material from considerable areas of the country. Dr. Reyment figures about 135 species and sub-species, many of them new, ranging in age from Middle Albian to Maestrichtian. He supplies a great deal of new information of both palæontological and stratigraphical importance.

The Albian faunas consist mainly of keeled ammonites of the Mortoniceratidae, most of them species already described from Europe, Angola, Zululand or Madagascar. The puzzling genus *Neokentroceras*, characterized by exceptional tuberculation in the small specimens which alone had been figured, is now shown to have outer whorls like those of many typical members of Mortoniceratinae, in which subfamily it must now be placed. One most surprising discovery was that of a new species of *Gyaloceras*, an inflated genus of Aconeceratinae, which was previously reported only from Queensland. Like most of the other genera of this subfamily of Oppeliidae, it will probably turn out to have a wide range.

The Nigerian Cenomanian has yielded few ammonites, but the Lower Turonian has produced abundant ammonites of great interest. These include, in particular, a wide range of genera and species representing the burst of radiation from the Acanthoceratidae which characterized the early Turonian. Much light is thrown on the relationships of some genera that have been long but ill known. In addition, there are full descriptions of a number of new genera and sub-genera which fill in gaps in the story of this burst of radiation.

Most of the known forms of the families Tissotiidae and Vascoceratidae (two of the groups derived from Acanthoceratidae) characterize the deposits of the Tethys, the Cretaceous 'Mediterranean' and tropical sea, and it has been impossible to work out any accurate correlation with more northerly Turonian, characterized by other families of ammonites. Special interest therefore lies in Dr. Reyment's discovery, in association with *Hoplitoides* and *Neoptychites*, of a few specimens of *Watinoceras*, a genus which occurs in North America, England, Turkestan and perhaps Japan, and is a valuable stratigraphic indicator.

The later ammonites include an interesting group of Coniacian species, some already described by Solger, and some small and unremarkable Santonian and Maestrichtian faunas.

The author makes a sensible use of subgenera and subspecies. Thus, while he describes all the distinct forms, he avoids that inflation of taxonomic scale which is a common and dangerous tendency on the part, particularly, of those who have to deal with abundant collections of well-preserved fossils of rapidly evolving groups. No doubt among the reasons for this welcome restraint is the fact that the author is a member of the Geological Survey of Nigeria, in close touch with the field staff, and also has himself collected a large part of the material he describes.

The monograph is very well produced, admirably illustrated both with plates and line-drawings and written with a refreshing clarity and absence of 'ammonite jargon'. It will be of particular value to all who work on the African Cretaceous; but, as already indicated, its interest and importance extend far more widely.

PROTEIN METABOLISM, RESPIRATION AND GROWTH*

A SYNTHESIS OF RESULTS FROM THE USE OF ¹⁴C-LABELLED SUBSTRATES AND TISSUE CULTURES

By PROF. F. C. STEWARD

Impact of Growth on Fresh Weight, Protein Metabolism and Respiration of Carrot Tissue Explants

The characteristics of the rapidly dividing cell might reside either in substances that are peculiar to the tissue treated with coconut milk or, alternatively, they may reside more in the *intensity* of certain processes than in their *nature*.

Therefore, one may ask whether the amino-acid composition of the protein in the rapidly dividing cells is different from that of the more resting cells. The amino-acid composition of the entire protein complement in the tissue was determined from the analytical data and the changes that occur with time may also be seen. To reveal the relative molar composition of the protein, the value of 10 was arbitrarily assigned to alanine. The composition of the protein under the different treatments and at

(* *Continued from p. 734*)

Table 4. MOLAR AMINO-ACID COMPOSITION OF PROTEIN IN FAST- AND SLOW-GROWING CARROT TISSUE EXPLANTS

(Rel. composition based on alanine = 10)

Amino-acid	Slow-growing tissue (no coconut milk)	Fast-growing tissue (+ coconut milk)
Aspartic acid	10·3	10·2
Glutamic acid	11·1	11·2
Serine	8·3	7·2
Glycine	11·2	12·8
Threonine	8·3	7·4
Alanine	10	10
Valine	8·3	7·2
Leucines	12·2	11·2
Lysine	3·6	5·6
Arginine	1·8	3·1
Proline	15·6	12·7
Hydroxyproline	9·8	4·5

the different times of sampling was strikingly similar, so much so that these were all pooled, and mean values calculated for all the tissues treated with coconut milk, irrespective of the radioactive substrates, and for all the tissues not treated with coconut milk. These data are summarized in Table 4. Thus, although the treatment with coconut milk had a very great effect on the *quantity* of protein in the tissues, this seems to occur without great effect upon its *amino-acid composition*.

Some differences are to be seen in these analytical data. Cultured carrot tissue, like cultured potato tissue, differs from the resting tissue in the intact organ in that it contains hydroxyproline in unexpectedly large amounts in the protein[15]. The significance of this is not yet known. Also, the protein of the fast-growing tissue probably contained relatively more glycine, lysine and arginine, while the protein of the slow-growing tissue contained somewhat more serine, threonine, valine and leucine in addition to proline. However, recognizing the great difference in biological activity of these two systems, the differences in protein composition seems small, and work on purified proteins would be required to establish that the fast-growing cells had a protein of characteristic amino-acid composition.

The total protein of the dividing cells seems to be richer in the basic amino-acids than that of the non-growing cells and in this resembles the bulk protein of certain plant growing points[16]. However, according to Easty and Ambrose[17], the amino-acid composition of the protein of kidney cells and of neoplastic tissue derived from them differ but little, and these authors ascribe the difference in their proteins to other features than the overall amino-acid composition.

What then does the coconut milk stimulus do? By measuring the effect of the coconut milk on various properties of the tissue one may see where it exerts its effect. To do this the value of the property in question as for the fast-growing tissue is expressed as a ratio to the similar quantity for the slow-growing tissue. This has been done for the following properties: (1) the incorporation of fresh weight by water absorption as the tissue grows; (2) the overall synthesis of total protein; (3) the total respiration per explant as measured by carbon dioxide production; (4) the rate of incorporation of carbon-14 activity into a variety of amino-acids both free and combined.

Some of the results are shown in Table 5. These lead to the following comments:

(1) There is a remarkable similarity in the acquisition of fresh weight and of total protein by the tissue stimulated to growth by coconut milk. This means that the acquisition of water by the growing cells is not merely osmotic in nature but is closely linked to the metabolism with which protein synthesis is concerned. In these tissue cultures stimulated to rapid growth, the increment of fresh weight should not, therefore, be considered merely as passive osmotic water absorption but rather that the water is actually being built into the structure of the cells and is as integral a part of its growth as the increment of total protein. This aspect of water absorption is, indeed, not new. Many recent papers since that of Bennet-Clark *et al.*[18] have stressed the fact of non-osmotic and metabolically activated water absorption by cells, and one of us earlier stressed that water uptake, salt accumulation, protein synthesis and a particular part of the aerobic respiration all were determined by similar variables in potato tissue slices which retained the ability to grow (ref. 13, cf. p. 415).

(2) The stimulus to the growing cells accentuated their total respiration much more than it accentuated their growth as measured by fresh weight or total protein. This disparity is shown by the ratios 3·7 and 5·1. Thus, the protein of the growing cell does not merely support respiration in accordance with its total mass; but, under the coconut milk stimulus, a given weight of protein is *much more effective in maintaining respiration*.

(3) In the incorporation of radioactive carbon into specific amino-acids of the protein there are evident effects of two kinds. These are illustrated, on one hand, by the amino-acids glutamic acid, aspartic acid and threonine and, on the other, by proline and hydroxyproline. In all these cases substantial amounts of radioactivity were incorporated in the amino-acids of the protein from the substrates supplied. In one type of situation, illustrated by proline and hydroxyproline, the increased incorporation of radioactivity into these amino-acids caused by coconut milk is approximately measured by the increased *total* synthesis of protein which occurred. (Whereas fresh weight and total protein were stimulated 3·7 times by the coconut milk treatment, the incorporation of proline and hydroxyproline was also stimulated about three times. The incorporation of carbon-14 in the proline and hydroxyproline of the protein was also stimulated about three times.) The other amino-acids, however, behaved quite differently because the incorporation of radioactivity from their substrates into these amino-acids in the protein was stimulated by the coconut milk treatment *far in excess* of the stimulus to total protein synthesized. However, the effect of coconut milk in stimulating incorporation of carbon-14 into the amino-acids glutamic, aspartic and threonine of the protein is the

Table 5. IMPACT OF GROWTH ON FRESH WEIGHT, RESPIRATION AND PROTEIN METABOLISM

Relative increase due to growth = ratio of (*a*) fresh weight, (*b*) total protein, (*c*) respiration, (*d*) ^{14}C-activity in protein amino-acids of the fast- to the slow-growing tissue

(All data refer to Period 5 (85–109 hr.))

				^{14}C-activity in protein amino-acids				
Property	Fresh weight	Total protein	Total respiration	Glutamic acid	Aspartic acid	Threonine	Proline	Hydroxyproline
Ratio $\frac{\text{fast growing}}{\text{slow growing}}$	3·7	3·7	5·1	5·6	4·6	5·2	3·9	2·0
					5·2		3·0	

same as the degree of stimulus conveyed by the coconut milk to the total respiration.

This close relation between respiration and the latter amino-acids is derived from their origin from carbon skeletons, formed by glycolysis or the tri-carboxylic acid cycle, and the incorporation of their carbon into protein—this incorporation proceeding more readily from glucose than from free amino-acids. The connexion between respiration and the endergonic processes of assimilation and synthesis is now well established from work with higher plants and micro-organisms. Ways in which respiration may be regulated, through its coupling with phosphorylation and oxidation-reduction, have been considered with particular regard to the synthesis of protein[19,20]. For the system now under consideration, another connexion between respiration and protein metabolism may be visualized, as shown in Fig. 1.

Part of the respiration varies with the rate of protein turnover. Part of the carbon dioxide of respiration originates from protein which is broken down, and thus the pace of alternating protein synthesis and breakdown will determine the extent of carbon dioxide that emerges by this route (phase 2 of Fig. 1). It is this component of the respiration which may be greatly stimulated in the fast-growing tissue, so that the apparent efficiency of the protein contained in the tissue to produce carbon dioxide, as shown by the ratios in Table 5, is much greater than the slow-growing tissue.

Thus, one may visualize the total bulk of protein as consisting essentially of two moieties. One element of the protein remains relatively steady; the other actively undergoes alternating synthesis and breakdown, and, in this latter sequence, it is linked with part of the respiration as measured by carbon dioxide production. This means that a part of the carbon which emerges as carbon dioxide may do so after it has been built into the protein molecule. Moreover, from the other data referred to, it is apparent that *the incorporation of carbon in the protein molecule proceeds much more readily from glucose than from the free amino-acids of the tissue.*

On the other hand, some free amino-acids do incorporate their carbon directly into at least certain of the proteins (for example, proline and hydroxyproline); but it appears that the particular protein moieties which are synthesized in this way represent proteins which are not in a metabolically active state of synthesis and breakdown but which, once formed, seem to constitute metabolically a 'point of no return'. Whereas the specific activity data clearly show that the proline of the protein could be embodied directly from the free proline in the cell, it is quite apparent that this could not occur with aspartic acid, glutamic acid, etc., for the specific activities of these substances in the protein bear no relationship to the specific activities of the substances as they occur free in the cell.

Respiration, Protein Synthesis and Breakdown: Some Parallel Situations

Older views of Warburg, recently revised[21,22], would have it that the rapidly dividing, or cancerous, cell has its fermentation stimulated to the point where it can obtain enough usable energy in the form of adenosine triphosphate to suffice for growth by cell division, whereas the normal cell can only achieve these ends through oxidative respiratory mechanisms. If this is so, though it is not accepted without question[23], it would not appear in the present work.

The present investigations lead to a different concept of the randomly proliferating plant cell. In the growing cells there are apparently several routes by which carbon dioxide can emerge. The familiar glycolytic–Krebs cycle pathway and its alternative, the gluconic acid shunt, may all apply to some extent. In the rapidly growing cells, however, it is necessary to recognize the interaction of protein metabolism and respiration because the carbon which enters into metabolically active protein now appears to emerge through protein breakdown, the release of amino-acids, the formation of amides, the deamidation and deamination of these substances to produce carbon skeletons which may be oxidized away to form carbon dioxide. Such carbon skeletons may enter the Krebs cycle as alternatives to the products of glycolysis[13]. Overall, this can result in the incorporation of carbon from sugar into protein and its eventual emergence as carbon dioxide; but the pace of this process may be conditioned by the pace of alternating synthesis and breakdown of the metabolically active moiety of the protein.

The peculiarity of the stimulus to rapid cell division, caused by the coconut milk growth factors, is that it not only enriches the protein content of the cells as a whole but it may also increase, in a disproportionate way, the importance of the protein turnover and of the associated respiration.

In this connexion it is of interest that Vrba[24] has re-emphasized the role of protein breakdown and re-synthesis in brain during muscular exercise. Not only is there seen to be an accentuated turnover of protein in a "cyclical process of degradation and resynthesis of the protein fraction of brain nervous tissue" but "during this process free glutamine is formed from the free glutamic acid, which is simultaneously an initial link for the phase of resynthesis". The parallel is clear.

By contrast the less-active moiety of the tissue protein, which once formed does not break down again, is only affected by the growth stimulus in the proportion that the total protein is increased and to the same extent that cell number and fresh weight are also increased.

Thus the rapidly dividing, proliferating, tumorous-like cells of these rapidly growing tissue cultures stimulated by coconut milk stand in sharp contrast to many viruses. These, and particularly tobacco mosaic virus, divert the protein metabolism of the host cell into the synthesis of virus protein which, once formed, is not reincorporated into metabolism. It constitutes, therefore, a "point of no return" (see ref. 15, p. 553, for references there cited). The coconut milk, however, stimulates that moiety of the protein which is metabolically active and which, through alternating synthesis and breakdown, can contribute to the total respiration and energy exchanges for the physiological use of the growing cell.

The stable, metabolically inactive protein moiety which does not 'turn over' may have more than merely structural properties. This fraction could possess and exert enzyme activity, and indeed there are many other indications that enzyme activity is unequally divided between different kinds of protein fraction to be found in cells.

Final Conclusions

The value of plant tissue cultures used under conditions which contrast in the rapidly growing and the slow growing states will now be evident. By recognizing and making use of the complications of growth and metabolism, conclusions can be derived that are unattainable if biochemical study is only upon systems which attempt to eliminate these complexities.

Much modern biochemistry is pre-occupied with cellular particles and particulate preparations. However, the study of metabolism in relation to growth, as here described, requires work on the whole cell to reveal the integrated operation of the whole system. Smuts's principle of "Holism"[25] applies here, for "The whole is not something additional to the parts: it is the parts in a definite structural arrangement and with mutual activities that constitute the whole" (loc. cit., p. 104).

In the use of radioactive substrates to reveal metabolic sequences it is therefore necessary to recognize the existence of separate phases or compartments in the cell and to recognize that in each of these, quite different reactions may involve simultaneously the same substrate; but it is also encouraging that these complications can be surmounted. The means to do this is to determine, for all available tissue constituents, not merely the existence of radioactivity in a given compound, not merely the specific activity of the tissue metabolite at a given time, but, by the investigation of time sequences, to make an estimate of the average specific activity of the carbon which must have been involved in the metabolic change that occurred. From the relations which these calculated results bear to the known specific activity of the source supplied, it is possible to appreciate the kind of complications that occur within the cell. Since this enables the investigator to recognize clearly that reactions occur in different compartments of the cell and to recognize that the total complement of a given constituent is made up of at least two different metabolic pools which do not mingle, this adds a valuable technique to the carbon-14 tracer method.

Even a relatively simple experiment, when planned to deal with all these complications, becomes a formidable task. To solve these problems, teamwork becomes essential, and this was happily achieved in the present case by pooling resources of personnel, equipment, technique and even substances synthesized from three different laboratories in three different countries.

It is too soon and perhaps too optimistic to suggest that the results here described could be applied directly to the investigations of cancerous growth in animal organs. The possibility, however, remains that the characteristic properties of the cancerous cell, like those of carrot cells stimulated by coconut milk, may lie not so much in distinctive substances and reactions as in accentuated rate of 'turnover' of their metabolically active, labile constituents owing to enhanced synthesis and breakdown. Investigations of nitrogen metabolism[26] in relation to cancer seem not to have considered this possibility. In plants this cyclical process may in part control the release of usable energy via a phase of respiration which is peculiarly linked with the ability of the cell to grow by cell division and to utilize metabolic energy for assimilation in such processes as water intake and salt accumulation. If these results have wider application, this pioneer experiment will indeed have been justified, and this general account will have achieved its purpose.

The full details of the work will be published elsewhere in due course.

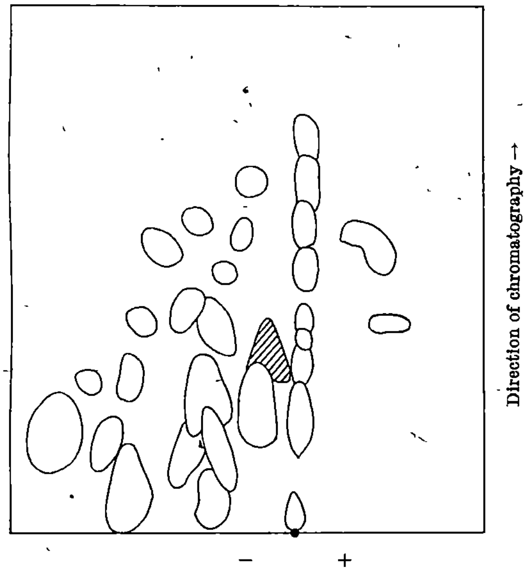
A SPECIFIC CHEMICAL DIFFERENCE BETWEEN THE GLOBINS OF NORMAL HUMAN AND SICKLE-CELL ANÆMIA HÆMOGLOBIN

By Dr. V. M. INGRAM

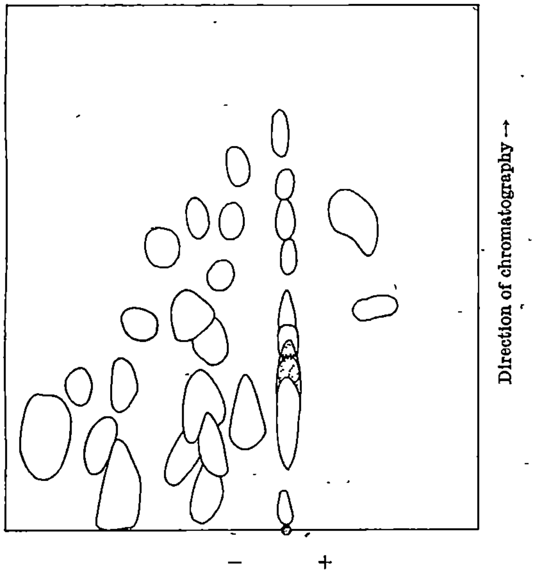
Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems, Cavendish Laboratory, University of Cambridge

A NEW and rapid technique of characterizing the chemical properties of a protein in considerable detail has been devised; by its application a specific difference is found in the sequence of amino-acid residues of normal and sickle-cell hæmoglobin. This difference appears to be confined to one small section of one of the polypeptide chains.

Of all the abnormal human hæmoglobins, the one that has been most intensively studied is hæmoglobin *S* from patients with sickle-cell anæmia. In 1949 Pauling and his collaborators[1] demonstrated by electrophoretic experiments that at neutral *p*H the hæmoglobin *S* molecule has a net charge which is more positive by three units compared with the normal molecule, hæmoglobin *A*. It has since been suggested[2] that this difference is really due to hæmoglobin *S* having fewer free carboxyl groups than does hæmoglobin *A*. It is also known that in the reduced state the abnormal protein has a much lower solubility[3]. However, careful determinations of the amino-acid composition of the two proteins[4,5] did not show any significant differences between them within the accuracy of the methods employed. Comparison of the N-terminal[6] and C-terminal[7] amino-acids and of the sulphydryl groups[8] was equally disappointing. On this evidence alone, it is not possible to decide whether the difference between the proteins, which is in any event small, lies in the amino-acid



Sickle cell hæmoglobin



Normal hæmoglobin

Fig. 1. 'Finger prints' of human normal and sickle-cell hæmoglobins. Electrophoresis at pH 6·4, chromatography with n-butyl alcohol/acetic acid/water (3 : 1 : 1). The shaded and the stippled spots are those belonging to the peptide showing the difference

sequences of the polypeptide chains or whether it lies in the folding of these chains leading to a masking of some amino-acid side-chains.

Hæmoglobin is still too large a molecule for detailed analysis of amino-acid sequence. However, it was thought that if a rapid method could be found of characterizing the chemical properties of the peptides in a tryptic digest, then perhaps a replacement of even a single residue for another might be detected without elaborate analysis.

The action of trypsin on proteins is at present the most reliable way of splitting a peptide chain at specific peptide bonds. The enzyme attacks only those bonds which are derived from the carboxyl group of the amino-acids lysine and arginine. There are about sixty of these in the hæmoglobin A and S molecules[5], but since it is expected[9] that each molecule is composed of two identical half-molecules, the number of peptides obtained by the action of trypsin should be about thirty, with an average chain-length of ten amino-acids. Small differences in the two proteins will result in small changes in one or more of these peptides. These should be detectable when the mixture is examined by a two-dimensional combination of paper electrophoresis and paper chromatography. It was decided to call the resulting chromatogram the 'finger print' of the protein.

To prepare such a 'finger print', samples of purified[10] hæmoglobins A and S were denatured by heat at 90° C. for 4 min. and digested with trypsin (2 per cent by weight) at pH 8 and 37° C. for 43 hr. Aliquots of these digests (equivalent to 3 mgm. of protein) were placed on large sheets of Whatman No. 3 MM paper between glass plates and subjected to electrophoresis[11] in pyridine/acetic acid at pH 6·4 for 150 min. at 16 V./cm. The paper was then dried. Ascending chromatography with n-butyl alcohol/acetic acid/water (3 : 1 : 1) and development of the peptide spots with ninhydrin produced the chromatograms shown in the tracings of Fig. 1. When the papers were run strictly in parallel, reproducibility was often good enough to superimpose the spots belonging to similar peptides in the two chromatograms.

The 'finger prints' show approximately thirty peptide spots, as was expected from the amino-acid composition. This confirms the view that the human hæmoglobin molecule consists of two identical half-molecules and not of four identical sub-units each carrying one of the four hæme groups. The same number of peptides was found for both hæmoglobins, as was to be expected from their containing the same number of lysine and arginine residues. Most of the peptides are well resolved, and appear to be similar in the two proteins. However, there is one peptide spot clearly visible in the digest of hæmoglobin S which is not obvious in the hæmoglobin A 'finger print'. In the tracing it has been marked by shading. Apart from its position, this peptide is characterized by its orange-colour reaction with

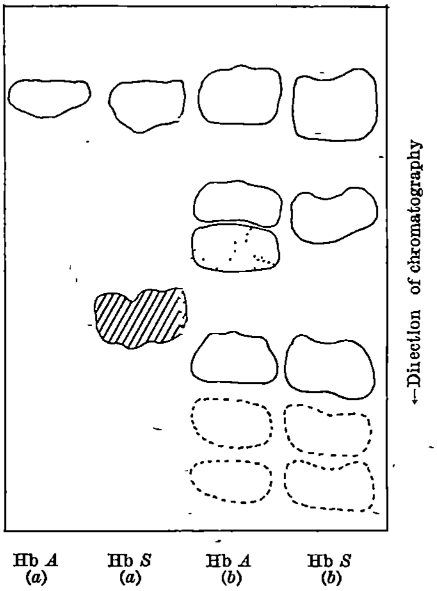


Fig. 2. Chromatogram of fractions of hæmoglobin A and S digests obtained by large-scale paper electrophoresis. (a) Slowest moving positively charged fractions; (b) neutral fractions

ninhydrin. Close inspection of the 'finger print' of hæmoglobin *A* shows the outline of an orange peptide spot in the 'back-bone' of neutral peptides which are not separated by electrophoresis. This spot, which has been stippled in the tracing, is not present in the neutral fraction of the digested hæmoglobin *S*. However, the neutral peptides are not really well separated by this two-dimensional technique.

Accordingly, larger amounts of the digests from both hæmoglobins were run in one direction only, using the electrophoretic conditions described earlier. Many bands were obtained. Both the band of neutral peptides and the slowest of the positively charged bands were eluted in each case, but separately. The eluted peptide mixtures were subjected to descending chromatography with *n*-butyl alcohol/acetic acid/water (4 : 1 : 5). Fig. 2 is a tracing of the chromatogram obtained showing the behaviour of the 'extra' or 'sickle cell' peptide in the two digests. This confirms that there is a particular peptide in the neutral fraction of the hæmoglobin *A* digest, which in the hæmoglobin *S* digest is shifted to the slowest positively charged zone. In addition, the R_F value of the hæmoglobin *A* peptide in the chromatographic solvent is lower than that of the analogous peptide derived from hæmoglobin *S*.

Summarizing the results of the electrophoretic and chromatographic examination, it can be seen that there is one peptide among the thirty or so which in hæmoglobin *S* is positively charged, but which is uncharged at the same pH in digests of hæmoglobin *A*. This agrees with the higher net positive charge[1] of the parent protein, hæmoglobin *S*. There is also a small change in the chromatographic behaviour of the peptide. On the other hand, corresponding pairs of all the other peptides show similar behaviour in these separating systems and therefore probably have similar constitutions.

One can now answer at least partly the question put earlier, and say that there is a difference in the amino-acid sequence in one small part of one of the polypeptide chains. This is particularly interesting in view of the genetic evidence[12] that the formation of hæmoglobin *S* is due to a mutation in a single gene. It remains to be seen exactly how large a portion of the chains is affected and how the sequences differ.

Full details of these experiments will be reported elsewhere. I am indebted to Dr. A. C. Allison (Oxford) and Dr. G. Seaman (Cambridge) for supplying samples of hæmoglobin *S* and blood from patients with homozygous sickle-cell anæmia ; and I acknowledge the encouragement and interest shown by Dr. M. F. Perutz, and the expert assistance of Mrs. Leslie Barnett and Miss Rita Prior.

IDENTIFICATION OF A NEW NORMAL EMBRYONIC HÆMOGLOBIN

By Dr. I. HALBRECHT and C. KLIBANSKI

Rogoff Clinical Research Laboratory, Workers Sick Fund Kupat Holim Beilinson Hospital, Petah Tikva, Israel

DURING a current study of the process of formation and appearance of the two hitherto known types of normal hæmoglobin, and of the different serum protein fractions of the fœtal blood throughout the various stages of embryonic life, we were able to examine the blood of a ten-week old embryo, recovered from an intact extra-uterine pregnancy. To the best of our knowledge this is the smallest human embryo of which blood chemistry data have been reported in the literature.

Using the method described by Singer[1] we found that the hæmoglobin of the ten-week old embryo consisted of 83 per cent of the alkali-resistant type.

The electrophoretic examination of this hæmoglobin was carried out in a Thomas paper electrophoresis apparatus on Whatman No. 1 filter paper using a veronal buffer solution of 0·04 ionic strength at 8·6 pH. In a 20-hr. run at 150 volts and 1·5 m.amp. per in. of filter paper a 3 per cent hæmolysate of this embryonic hæmoglobin, prepared by Drabkin's[2] method, showed a definitely slower mobility compared with the electrophoretic mobility of adult hæmoglobin used as control as shown in Fig. 1.

Later on we discovered an embryonic hæmoglobin with an identically slow electrophoretic mobility in the blood of a 20-week old fœtus weighing 450 gm. The concentration of the alkali-resistant type of hæmoglobin in this blood was 52 per cent. The electrophoretic mobility of the embryonic hæmoglobin was compared both with that of hæmoglobin recovered from cordal blood of a full-term newly born with approximately the same concentration of alkali-resistant fraction and with adult hæmoglobin. The hæmoglobin of the 20-week old fœtus showed a distinctly slower mobility as compared with both the newly born's cordal blood and the adult hæmoglobin. A mixture of the embryonic and the newly born's cordal blood hæmoglobins showed an electrophoretic mobility between both, as shown in Figs. 2 and 3.

The fact that, on one hand, the hæmoglobin of the embryonic and of the newly born's cordal blood, containing the same percentage of the alkali-resistant type of hæmoglobin, moved with different mobilities, and on the other hand, the hæmoglobins of the two embryos (Fig. 3, *a* and *c*), although differing substantially in their concentration of the alkali-resistant fraction, had the same mobility, is of special significance. It indicates that the difference in the electrophoretic mobility of these two embryonic hæmoglobins on one hand, and the cordal blood hæmoglobin of the newly born on the other hand, is not due to different concentrations of the alkali-resistant hæmoglobin fraction. It is due to the presence of a different hæmoglobin in the red blood corpuscles of early embryonic life.

This third hæmoglobin may be identical with a new embryonic hæmoglobin for which Allison[3] has recently proposed the name of "primitive type P" of normal hæmoglobin. According to this author, the synthesis of this hæmoglobin seems to be under a different genetic control from that of the hæmoglobins of later fœtal life. This appears to have been definitely established for the early embryonic hæmoglobin of the mouse.

Further investigations are being undertaken in our laboratory to elucidate the characteristics of this new type of normal hæmoglobin. We are especially attempting to determine the process of its disappearance from the fœtal blood and the eventual pathogenic role of abnormal persistence of this hæmoglobin beyond embryonic life.

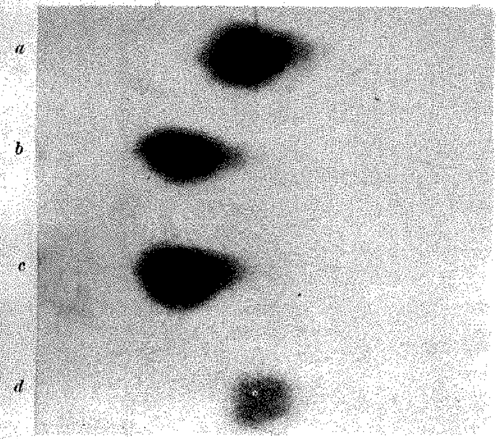

Fig. 1. Comparison of the electrophoretic mobilities of the new embryonic and adult hæmoglobins

a and *e*, normal adult hæmoglobins; *b*, embryonic hæmoglobin from a 20-weeks old fœtus; *c*, hæmoglobin from the cordal blood of a full-term newly born; *d*, mixture of the embryonic and the newly born's cordal blood hæmoglobins

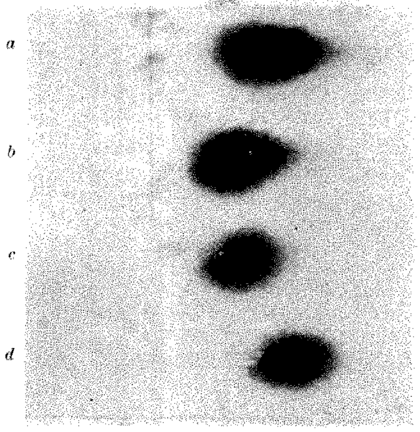

Fig. 3. Comparison of the electrophoretic mobilities of the new embryonic hæmoglobin with those of hæmoglobins from thalassæmic and normal adult blood
a, hæmoglobin from the blood of a nine-months old child with thalassæmia and 32 per cent of alkali-resistant hæmoglobin fraction; *b* and *c*, embryonic hæmoglobins from the ten- and twenty-week-old embryos, respectively; *d*, normal adult hæmoglobin

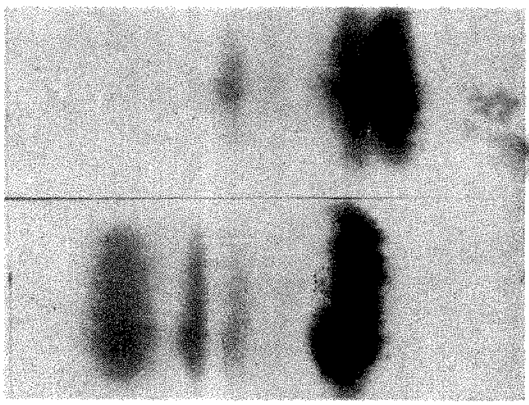

Fig. 4. Electrophoretic pattern of the serum protein of a ten-week-old embryo as compared with that of a normal adult serum (below)

An unusual electrophoretic pattern was found in the serum of the 10-week old embryo, with a total protein content of 2·8 gm. per cent (Fig. 4). In this serum five protein fractions were found, a small one corresponding to α_1 globulin and two others to α_2 and β globulin fractions of a normal adult blood serum, used as control in the same run. Of the two remaining protein fractions with electrophoretic mobilities close to that of the albumin fraction of the adult serum, one of them was not superposable on any fraction of the normal adult or of any new-born cordal blood serum. This fraction may be specific for the blood serum of early embryonic life.

No γ globulin fraction could be found in the serum of the ten-week-old embryo, indicating perhaps that the gamma globulin is formed during the embryonic life much later than the other serum protein fractions.

This study was in part supported by a grant from Dr. William Levine, Brooklyn, New York.

Effect of the Local Chromosomal Environment upon the Genotype

Critical data bearing on the question of gene-conversion were obtained by analysis of a yeast hybrid heterozygous for nine different genes. Thirty-four tetrads from a single family heterozygous for the genes controlling cadmium-sensitivity vs. resistance (*CD*/*cd*)[1] and fermentation of methyl-α-D-glucopyranoside (*MG*/*mg*) were obtained from a single hybrid in which most of the nine loci segregated regularly. In addition to *CD* and *cd* a third phenotype (cd^M) was characterized by capacity eventually to achieve cadmium-resistance, presumably by mutation—a potential lacking in the *cd* genotype. The three types are indicated by a three-membered ratio *CD* : cd^M : *cd* (Table 1).

Tetrad analysis makes it possible to establish a presumptive difference between recombinations produced by gene-conversion and recombinations produced by crossing-over.

Table 1

(*a*)	*CD MG*	*CD MG*	*cd mg*	*cd mg*	24	
(*b*)	*CD MG*	*CD mg*	*cd MG*	*cd mg*	2	(18,177 and 18,181)
(*c*)	*CD MG*	*CD mg*	*cd mg*	*cd mg*	1	(18,285)
(*d*)	$cd^M MG$	$cd^M MG$	*cd mg*	*cd mg*	1	(18,257)
(*e*)	*CD MG*	$cd^M MG$	*cd mg*	*cd mg*	1	(18,289)
(*f*)	*CD MG*	$cd^M MG$	$cd^M mg$	*cd mg*	1	(18,341)
(*g*)	*CD MG*	*cd MG*	$cd^M mg$	*CD mg*	1	(18,253)
(*h*)	*CD MG*	*cd MG*	$cd^M mg$	$cd^M mg$	1	(18,281)
(*i*)	$cd^M MG$	*CD mg*	$cd^M mg$	*cd mg*	1	(18,297)
(*j*)	$cd^M MG$	$cd^M mg$	*cd mg*	*cd mg*	1	(18,193)

No recombinants between *CD* and *MG* were found in the first twenty-four tetrads. Tetrads (*b*) contained recombinants (underlined) produced by crossing-over. Tetrad (*c*) contained one recombinant (*CD mg*) resulting from gene-conversion (*MG mg mg mg*).

In tetrads (*d*) and (*e*) both *mg* segregants are *cd*, suggesting that the cd^M genes arose by conversion of *CD* to cd^M. In (*f*) one *CD* gene converted to cd^M and one *cd* gene to cd^M. In (*g*) and (*h*) recombinant segregants occur. In (*g*) it appears that a *cd* gene had converted to cd^M and (if this is correct) that a cross-over between *CD* and *MG* had occurred simultaneously. In (*h*) a similar event may have occurred with one *CD* converted to cd^M.

Conversion of *MG* to *mg* occurred in (*i*) and (*j*); in (*i*) conversion of *CD* to cd^M and *cd* to cd^M may have occurred, while in (*j*) conversion of both *CD* genes to cd^M is indicated.

Table 2 shows the genotypes of two parents and the types of segregation in thirty-four hybrid tetrads. In twenty-two tetrads every gene-pair segregated regularly; in five tetrads individual gene pairs segregated irregularly. The remaining seven tetrads showed respectively 2, 2, 2, 3, 3, 3, and 5 irregularities each. The only tetrad irregular for *MA*/*ma* was also irregular for *MG*/*mg*; previous data gave no evidence of dependence[2].

The genes controlling the synthesis of anthranilic acid and histidine are linked[3], and both underwent conversion together in two tetrads, while each was converted once in two other tetrads.

The genes *AN* and *PR* are on different chromosomes, but their conversion is apparently interdependent. The chromosomes carrying these genes segregate in a non-random manner, presumably by synapsis of non-homologous centromeres[4].

In the last tetrad the five gene-pairs undergo conversion concurrently. The *AN* and *PR* genes were converted to the dominant state whereas *MG*, *CD* and *HI* were converted to the recessive state.

Both parents required adenine for growth and neither parent was pink, indicating a further lack of some undefined synthetic capacity. The ability to synthesize methionine is essential for the production of pink pigment in adenine-dependent cultures[5]. Eight asci produced one pink culture; three produced two pinks, while twenty-three produced none. All cultures were tested for their ability to grow in medium lacking adenine. None of the pink cultures could grow in its absence, but thirteen tetrads contained single clones which grew in the absence of adenine after a longer delay than usual for a clone carrying the standard dominant gene. One tetrad contained two such 'slow' clones. Local deficiencies (or excesses) of the materials required for the synthesis of nucleic acids might be expected in cells unable to synthesize adenine. When adequate (or excessive) material is present in a specific position,

Table 2. Types of Segregations of 9 Gene-pairs in 34 Tetrads of One Family

The 2-membered ratios are dominant : recessive; the 3-membered ratios are dominant : intermediate : recessive. The numbers in parenthesis indicate the tetrad serial number. Non-Mendelian ratios are underlined.

both dominant genes might be reconstituted and some of the excess used for converting at least one of the defective recessive alleles into a functional dominant, producing a 3 : 1 ratio. When a region suffers a deficiency of constructional materials, it might not always be possible to build a second dominant allele to match the one already present, and a 1 : 3 ratio occurs. Since linked genes (or genes juxtaposed by non-homologous synapsis) behave similarly, it may be inferred that the deficiencies (or excesses) are non-specific. The fact that both excesses and deficiencies of dominants (3 : 1 and 1 : 3) occur in the same cell suggests that nutritional irregularities may be highly localized and that problems of transport are involved.

Emerson's[6] attack on the demonstrability of gene conversion in *Saccharomyces* considers only phenotypic ratios, whereas in the demonstration of gene conversion involving 1 : 3 phenotypic ratios of one gene linked to four others[7], the regular behaviour of the other four genes remains to be explained. His proposal yields contradictory interpretations when applied to a 'conversion' pedigree involving twenty-five families and twelve generations[8]. He does not mention the crucial papers[9] on conversion of the multiple alleles of *MZ* and he cannot explain the present results.

Our work has been supported by grants from the National Cancer Institute of the National Institutes of Health, Public Health Service, *C*-2140, and from the Illinois Division of the American Cancer Society.

Sex Chromatin as an Aid to the Identification of Sex in Forensic Medicine

THE existence of a sex difference in the morphology of intermitotic nuclei may be of importance, not only anatomically and clinically, but also for its value as an additional method of sex determination in forensic medicine. We have already shown[1,2] that the presence of sex chromatin in the female nucleus can be utilized to determine the sex of unfixed human tissues which have been immersed in water or exposed to atmospheres of varying humidity and temperature. This nuclear feature persists for a period of 2–3 weeks, depending on the nature of the environment in which the tissues decompose.

Further investigations in this Department on the persistence of sex chromatin after death have since been made and emphasize the importance of our previous findings. Portions of full-term human female fœtal tissue were buried in direct contact with the soil, some two feet from the surface. At regular intervals small fragments of skin, muscle and cartilage were removed, prepared by routine histological techniques and the nuclei examined for the presence of sex chromatin. The sex of the tissue could be determined in this way with certainty for four weeks after burial, which was considerably longer than had been the case with tissues degenerating in other environments.

Previously, we compared the persistence of sex chromatin in cartilage cells of fixed and unfixed material and noted that while this mass of chromatin is particularly well seen in fixed cartilage cells from female subjects, in unfixed cartilage its period of survival is no greater than in other tissues. This fact has been confirmed in cartilage cells of young fœtal material by Gleaister[3]. We have also found that articular cartilage removed from joints with hitherto intact capsular tissues possesses no advantage in post-mortem sex determination. The cells of the dental pulp in extracted teeth were examined in anticipation that, being virtually sealed from their surroundings, nuclear detail might be preserved for an extended period. However, sex chromatin persists for only 24 hr. in isolated teeth and for a maximum of one week in teeth immersed in physiological saline, the latter being considered to simulate the environment of teeth *in situ* after death. We conclude, therefore, that sex chromatin persists for a similar length of time in the majority of tissues.

A method has been described for the determination of sex from blood films[4]. We have attempted to determine sex in this way from an examination of blood on scalpel blades used in the dissection of fresh post-mortem tissues, but find it of no value, due to hæmolysis with complete destruction of white blood cells. However it is often possible to determine sex from accompanying epithelial cells transferred from the skin, even on blades afterwards kept in room air for a number of weeks. A preliminary investigation into the possibility of sexing human hairs in a similar way, from epithelial cells adhering to the roots of hairs removed from the scalp, indicates that, as with material adhering to instruments, diagnosis can be made.

Reference to the most recent text-books of forensic medicine reveals that the original work on sex chromatin by Murray Barr and his colleagues only receives mention by Polson[5], and no suggestion has yet been made as to the possible medico-legal significance of this aspect of cell morphology. The results of our investigations, which will be published more fully, show that the sex of small fragments of mutilated tissue, of material adhering to instruments and of human hair can be determined, in certain circumstances, from the appearance of nuclear chromatin.

The Fine Structure of Bone

X-RAY crystallographic studies by Engström and his collaborators[1,2] have shown that the apatite crystallites of bone have linear dimensions of about 220 A. × 65 A. The crystals were aligned with their long axis parallel to the collagen fibre axis, and it was suggested that there may be three such inorganic crystals for each 640 A. period of the collagen fibril. In a recent communication, Fernández-Morán and Engström[3] observed a "predominance of rod- or needle-shaped apatite particles 30–40 A. wide and about 200 A. long" in thin sections of bone by means of electron microscopy. This result is in reasonable agreement with those obtained by X-ray diffraction; but no evidence is offered that the regions of higher density present in the micrographs (which appear to have reproduced badly) were in fact due to apatite. Nor is it clear whether electron microscopy has provided any further evidence as to the manner of alignment of the particles, for Robinson and Watson[4] have identified apatite in thin sections of bone by means of electron diffraction, and have indicated that the particles were deposited on the 'doublet' band region of the period of the fibril.

Electron microscopy and X-ray diffraction, however, have not given unequivocal results regarding the site of the apatite particles; but work in this Laboratory has clarified the position to some extent[5]. In this work transverse and longitudinal sections of undecalcified embryonic avian bone were cut with a glass knife, and viewed in a modified Metropolitan-Vickers (*E.M.*III) electron microscope. Densitometer traces of electron micrographs of newly formed osteogenic fibrils demonstrated at least five bands and five interbands within a main period of the collagen fibril. At an early stage of calcification, very dense particles, of less than 100 A. in size, became localized in a ring between the *d* and *ab* bands of the main period, that is, in the major region of indentation of the period (Fig. 1). In transverse sections of the appropriate part of the fibrils, the particles were seen to be irregular in outline, were about 100 A. apart, and numbered up to ten per ring.

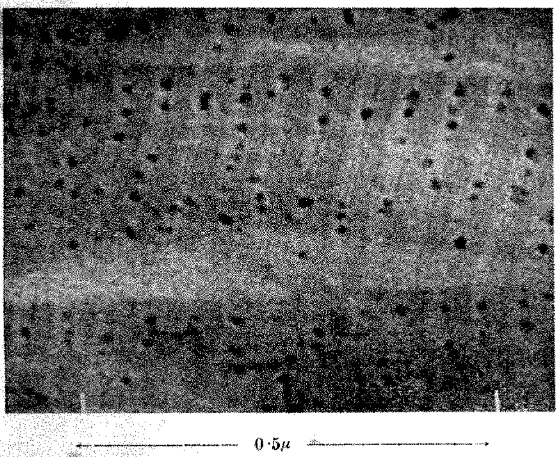

Fig. 1. A section of periosteal bone from a 16-day embryo, showing the periodic structure of the collagen fibrils; apatite particles are localized in one interband of each period, namely, between the *d* and *ab* bands. × 110,000

Measurements of the Bragg spacings of powder diffraction patterns, obtained by electron diffraction of such sections, were in close agreement with those obtained from a control specimen of hydroxyapatite. It is therefore considered that these particles are to be identified with the apatite component of bone. There was no clear evidence, however, from either electron microscopy or electron diffraction, of any preferred orientation of the particles with respect to the fibre axis. The observation on embryonic bone of the localization of dense apatite particles between the *d* and *ab* bands is precise, and it is believed that such clarity of deposition has not been recorded in previous work. This finding may also have a bearing on the mechanism by means of which the apatite crystals become preferentially orientated with their *c*-axis parallel to the collagen fibre axis already demonstrated by means of X-ray diffraction[1].

The Lateral Rectus Muscle and Sixth Cranial Nerve in the Pig

THE lateral rectus muscle and sixth nerve have been studied in four young pigs ranging in age from three to six weeks. Fixation of the orbital contents and brain stem was ensured by ante-mortem perfusions. The muscle was examined in frozen sections taken through longitudinal and transverse planes, and stained by the diammine silver ion technique[1]. A block of the brain stem extending from the upper medulla to mid-brain was treated by the Bielschowsky pyridine–silver process, and sections, namely, dorso-ventral, longitudinal and transverse, were examined. The trunk of the sixth nerve was studied in preparations stained by hæmatoxylin and eosin and by methylene blue.

The volume of nerve in the lateral rectus was calculated to be approximately 9 per cent. Four main types of ending were observed in the muscle: (1) motor end-plates, found most abundantly in the posterior and middle thirds; (2) muscle spindles of standard type, anteriorly placed and deep to the peripheral zone of small muscle fibres; (3) large numbers of longitudinal fibres connected by collaterals and ending freely in fine filaments on the muscle fibres; (4) tendon endings at the attachments of the muscle.

Nerve cells on the sixth nerve in man have been reported by Nicholson[2]. In two of our animals, a few small ganglia were observed adjacent to the fibres of the sixth nerve in the region of the cavernous sinus.

Each ganglion consisted of 8–12 small multipolar cells intermingled with groups of non-myelinated nerve fibres. These structures, being morphologically similar to autonomic ganglia, were regarded as fragments from the plexus on the wall of the internal carotid artery.

A small-celled component near the rostral limit of the abducens nucleus was studied with particular care. The cells here are not representative of first-order neurones, and their function is not known.

In the cat[3] and the pig[4,5] a contribution has been reported from the mesencephalic root of the fifth nerve to the trochlear nerve at its decussation. In the case of the sixth nerve, no similar direct connexion was evident. Investigations are now being carried out concerning a possible connexion between the first division of the trigeminal and the oculomotor nerves in the pig; such a connexion has been observed in man and certain mammals by other workers.

Milk Production and Interval between Milking

In a recent communication[1] results were presented challenging the generally accepted theory that secretion-rate in the dairy cow declines with time in the interval between successive milkings. These Ruakura experiments showed that secretion-rate was constant up to 20–24 hr. It was suggested that, under a twice-a-day milking regime, unequal intervals of considerable magnitude might be employed without any significant difference in milk yield due to direct pressure effects.

An experiment to test this has recently been completed at Ruakura. The work extended over two years. In the first year seven sets of monozygotic twins and in the second year eleven sets were milked such that one member of each pair was milked at equal 12-hr. intervals and the other member at intervals of 8 and 16 hr.

Mean productions for the complete lactations were:

	Year	No. of sets	Milk	Fat	Days
12—12	1954–55	7	5628·3	252·4	232
16—8			5461·4	246·1	232
12—12	1955–56	11	6438	316	264
16—8			6555	321	264

These results are not only of obvious theoretical interest but also have important implications for the dairy industry.

Preferential Uptake of Sulphone by Affected Skin Tissue of Leprosy Patients as detected by a Tracer Method

Diamino-diphenyl-sulphone and a number of its derivatives have been found to be very effective in the treatment of leprosy; but the exact mode of their action on the affected tissue and invading *Mycobacterium* has not yet been definitely established[1–3]. In the present work, diamino-diphenyl-sulphone labelled with sulphur-35 was used for studying the time variation of concentration of the drug in blood and healthy and diseased skin tissues of the leprosy patients. An interesting observation was that the drug was found to be localized to a greater extent in the affected tissues compared to healthy ones. Such studies were not possible with the help of earlier colorimetric techniques[4], as these required tissues in bulk. The method used here was found to be ten times more sensitive than the colorimetric techniques.

Diamino-diphenyl-sulphone labelled with sulphur-35 (procured from the Atomic Energy Research Establishment, England) was administered to nine patients as a single oral dose of 4 µc./kgm. body-weight. The specific activity of the drug was about 0·75 µc./mgm. After administration of diamino-diphenyl-sulphone, samples of skin tissues were removed by biopsy from affected sites as well as from adjacent healthy sites, at different intervals. These were finely minced and homogenized with distilled water. The suspension was then uniformly spread over previously weighed copper planchets and dried under an infra-red lamp. Simultaneously with skin samples, blood was also collected from each patient. 0·1 c.c. of blood was similarly dried on the pre-weighed copper planchets. The planchets were reweighed to get the thickness of the sample in mgm./cm.². The thickness of the deposits varied from 4–6 mgm./cm.². They were placed under a previously calibrated end-window Geiger–Müller counter (window thickness 2·8 mgm./cm.²) and the activity of the sample was deduced from the recorded number of counts per minute and the sample thickness[5].

The concentration of diamino-diphenyl-sulphone (sulphur-35) in the blood, healthy and affected skin tissues of the leprosy patient is shown in Table 1. It is apparent from the table that the concentration in the healthy skin runs almost parallel to the concentration in blood. Within an initial period of 6 hr. after administration, concentration in blood seems to be 2–3 times that in the healthy skin. If, however, a comparison be made of the concentration of the

drug in the diseased skin with that in the healthy, the relative concentration of sulphone is about ten times greater in the diseased site. No significant difference could be observed in the concentration of diamino-diphenyl-sulphone in the case of multiple lesions compared with those with single lesions. 72 hr. after the administration of the drug, the concentration in the blood or healthy skin was too feeble to be detected by our method.

Effect of Antibiotics on the Growth and Alkaloid Production of Tobacco Plants

Antibiotics are being used increasingly for the chemotherapy of plant diseases. In tobacco it has been proved effective to use streptomycin to control blue mould[1] and wildfire[2]. In *Datura stramonium*, Steinegger[3] showed that penicillin increased both the growth and alkaloid production. Nickell[4] stated that a change in the alkaloid content of tobacco plants by using antibiotics could be utilized to good advantage.

Several tests were made with Robinson Medium Broadleaf Maryland tobacco, using bacitracin, sodium penicillin, streptomycin sulphate, dihydrostreptomycin sulphate, terramycin hydrochloride and agrimycin 200 *C* (streptomycin 660 μgm./mgm.) supplied by Chas. Pfizer and Co. (The constant interest and help of Dr. R. A. Benedict, Mr. V. J. Carroll and Dr. L. G. Nickell, of Chas. Pfizer and Co., are acknowledged.)

Greenhouse solution cultures containing four concentrations of agrimycin 200 *C*. Agrimycin 200 *C* was added to the nutrient solution[5] at concentrations of 0, 10, 50, 100 and 200 p.p.m. of streptomycin. The fresh weights of the entire plants produced after two months in 2-litre crocks of this solution were 287, 336, 194, 110 and 59 gm., respectively. The percentages of total alkaloid on fresh-weight basis were 0·025, 0·024, 0·039, 0·047 and 0·019, respectively. The amounts of alkaloid per plant were 70·5, 80·3, 75·9, 51·7 and 11·1 mgm., respectively. Thus a small concentration of streptomycin appears to have been slightly beneficial; but larger concentrations were definitely unfavourable, causing more pronounced stunting and browning of the roots than of the tops; but at the highest concentration dead spots appeared on the leaves. Since growth was inhibited to a greater degree than alkaloid synthesis, a maximum alkaloid percentage, on a weight basis, was produced at 50–100 p.p.m. However, no evidence of specific increase in alkaloid synthesis was observed.

Greenhouse solution culture containing other antibiotics. The experimental conditions were similar to the preceding one except that larger nutrient solution containers were used. Since the structure of bacitracin is incompletely known, it was used at 5 and 20 units per litre. The other antibiotics were tested at concentrations of 50 and 200 p.p.m. The fresh weights of all other plants were less than the control (780 gm.), except the lower concentration of penicillin (782 gm.). In all cases the plants grown at the higher concentration of the antibiotic were smaller than at the lower. In the cases of the lower concentration of streptomycin sulphate, dihydrostreptomycin sulphate and sodium penicillin the quantity of alkaloid synthesized per plant was 317·1 mgm., 275·7 mgm. and 216·5 mgm., respectively, and was greater than the control (190·9 mgm.), tending to confirm the indications obtained at the lowest concentrations in the first experiment. Thus there may be an optimum concentration of each antibiotic in the nutrient solution at which the fresh weight and alkaloid synthesis are maximum; but if such optimum exists it is very low. This may be due to the influence of the antibiotic in depressing competitive development of micro-organisms in the nutrient solution. However, at higher concentrations all the antibiotics had an unfavourable effect on alkaloid synthesis as well as on fresh weight.

On examination of the antibiotic activity in the root, stem and leaves of these plants it was found that all parts of the plants which had received streptomycin and dihydrostreptomycin showed significant antimicrobial activity compared to the control. In the terramycin samples only the root gave significant activity, and significant activity was not found in any part of the bacitracin or penicillin samples.

Antibiotic sprays on the tops of plants grown in soil. The five antibiotics as used in the previous experiment were tested in this experiment, also. Bacitracin was used at 200 units per litre and the other four at 200 p.p.m. Tobacco plants were grown in 7-in. pots in the greenhouse. They were divided into three groups and each was sprayed with a given antibiotic twice, four times, or six times at intervals of 30, 15 or 10 days, respectively, during their growth period. No significant differences were found either in plant size or in alkaloid content per plant due to the antibiotic used or the frequency of spraying.

Field test on spraying with different concentrations of penicillin. Since penicillin showed an increase of both plant growth and alkaloid production of *Datura stramonium*[5] and also indicated how little it affected plant size in the solution culture, it was tried in the field by spraying ten times at intervals of 10 days throughout the growth period with several concentrations of penicillin; namely, 0, 50, 100 and 200 p.p.m. These four treatments, in four replications, were laid out in the field in a Latin square design. Statistical analysis of the results did not show any significant difference either in fresh weight of plant, in alkaloid concentration, or in total alkaloid produced per plant due to different treatments.

The experiments described above failed to show any effects on the plants produced by antibiotics sprayed on the leaves. They did demonstrate marked unfavourable effects of any considerable concentration of antibiotics in the nutrient solution. They showed some evidence of stimulatory effects of small concentrations in the nutrient solutions;

but these may be secondary effects. It appears improbable that such small concentrations could be provided reproducibly to the roots of plants growing in soil. Thus, commercially grown tobacco leaf of 'predesigned' alkaloid content does not appear to be feasible by any of the antibiotic applications described in this paper.

A Chemotactic Response in Wheat Bulb Fly Larvæ

The eggs of wheat bulb fly (*Leptohylemyia coarctata* Fall.) are laid in the soil during the summer and are usually found on fallow land or where there is a light cover of vegetation such as potatoes. The larvæ develop and remain in the egg in diapause until the following January or February. Meanwhile, such fields may have been autumn-sown with wheat which the larvæ infest upon hatching[1]. The mechanism by which the larvæ locate the wheat plants is the subject of this investigation.

Laboratory observations indicated that cut wheat shoots could be detected in Petri dishes by the larvæ when both larvæ and shoot were on damp filter paper; but when the shoots were separated from the damp paper by a cover glass laid under them the results were less positive. The use of growing plants was more desirable in tests and the following method was evolved. Wheat seeds were germinated on damp filter paper in Petri dishes and transplanted into a sodium alginate jelly when the first leaf emerged from the coleoptile. Identical dishes of jelly without wheat were made up simultaneously. In preliminary tests, cubes of jelly taken three or four days later from the wheat dish without including or damaging the roots or plants and similar cubes from the non-wheat jelly were placed on damp filter paper around the edge of a Petri dish, and newly hatched, unfed wheat bulb fly larvæ were introduced centrally. A large number of larvæ was later seen in the wheat jelly cubes.

To test this observation, ten Petri dishes were then arranged. The dishes were set up as follows, after minor adjustments in the first five: the jelly was made up to the formula of 1 gm. sodium alginate 'Manucol' *SS/LM* and 0·2 gm. calcium citrate to 100 ml. of water. In each dish one ¼-in. cube of wheat jelly and a similar one of non-wheat jelly were placed opposite and equidistant, ¼ in. away from the central ¼-in. square in which ten newly hatched larvæ were introduced. The dishes were orientated differently. The lids were marked out in ¼-in. squares and the positions of the larvæ which immediately began to move were recorded on correspondingly squared graph paper every ten minutes.

The larvæ began to aggregate quickly in the wheat jelly, the total number in the various sites after approximately 1 hr. being shown in Table 1.

Table 1. Larvæ found in Various Sites in Petri Dishes containing Cubes of Wheat and Non-wheat Jelly

Test	No. in wheat jelly	No. in non-wheat jelly	No. still wandering	Missing
1	7	2	1	0
2	1	0	9	0
3	6	1	3	0
4	4	1	5	0
5	1	1	8	0
6	5	0	5	0
7	4	1	4	1
8	7	0	3	0
9	5	0	5	0
10	4	1	5	0
Totals	44	7	48	1

The total area on which the larvæ could wander (including the sides and top of the cubes) per dish was 12·1 sq. in. The area of 1 cube (minus base) was 1·25 sq. in. while the proportion of the total area occupied by one cube was 0·104. The number of larvæ which could be expected in an area of cube size per dish would be 1·04 ± 0·43 should the wandering be of a random nature; but this is considerably exceeded by the larvæ in the wheat jelly. It is probable that an exudation from the wheat plants into the jelly and thence into the damp filter paper was detected by the larvæ.

The nature of the larval response is still being investigated, as is the constitution of the substance in the wheat jelly. The speed with which a substantial proportion of the larvæ find the jelly (in some experiments 60 per cent reached it within ten minutes) suggests that the response is a directional one (taxis); but the nature and speed of the movement may also be influenced (kinesis)[2]. The larvæ are able to leave the jelly after entering it and when exposed for 24 hr. they become dispersed over the dish. It is possible that by this time the substance in the wheat jelly has diffused more or less evenly throughout the dish.

Inhibitory Effect of Glucose on Enzyme Formation

The induced biosynthesis of many microbial enzymes is susceptible to the inhibitory effect of glucose[1]. The physiological significance of this phenomenon has been indicated by the study of an L-histidine-requiring mutant strain of *Aerobacter aerogenes* in which glucose inhibits the formation of histidase, thereby conserving the L-histidine for its specific role as growth factor[2]. Under conditions that permit a gratuitous, linear production of *myo*-inositol dehydrogenase (another inducible enzyme in *A. aerogenes*) in the absence of the inducing agent, the glucose effect is still operative, indicating that glucose interferes with the production of enzyme rather than with the process of induction[3].

Recently, it has been possible to demonstrate in two instances the reversal of the glucose inhibition of induced enzyme biosynthesis. In a wild strain of *A. aerogenes* L-histidine was substituted for ammonium sulphate, the customary nitrogen source of the glucose-containing minimal medium. In a mutant

Table 1. THE PRODUCTION OF HISTIDASE AND UROCANASE BY TWO STRAINS OF *A. aerogenes*

Strain	Growth Medium*				Histidase† (units/10 mgm. cells)	Urocanase† (units/10 mgm. cells)
	L-Histidine	Glucose	$(NH_4)_2SO_4$	L-Glutamate		
Wild	+	−	+	−	170	403
	+	−	−	−	182	420
	+	+	+	−	< 5	< 5
	+	+	−	−	70	220
L-Glutamate-requiring mutant	+	−	+	+	203	398
	+	−	+	−	197	366
	+	+	+	+	< 5	< 5
	+	+	+	±	65	130

* These substances were added, where indicated, to the basal salt medium in sufficient amounts to give a final concentration of 0·2 per cent.

† Histidase and urocanase are the first two enzymes in the series degrading L-histidine to L-glutamic acid, formamide and ammonia (ref. 4). They were assayed by determining the ability of dried-cell preparations to degrade L-histidine and urocanic acid, respectively (ref. 3). One unit of enzyme is defined as that activity which results in the degradation of 0·1 micromole of substrate in 1 hr. under the conditions of the assay.

strain of this organism (kindly supplied by Dr. B. D. Davis, of New York University) which required L-glutamic acid for growth, L-histidine was substituted for L-glutamic acid in a glucose–ammonium sulphate medium. In both cases the production of histidase in the presence of glucose was a prerequisite for growth, and both conditions resulted in growth of the cells and the formation of the histidase series of enzymes (Table 1).

These observations demonstrate that glucose permits histidase biosynthesis in *A. aerogenes* when the action of this enzyme system furnishes products necessary for growth and not obtainable from the degradation of glucose. Conversely, glucose inhibits histidase biosynthesis when the products of the reactions catalysed by this enzyme system merely augment the supply of metabolites resulting from glucose degradation.

Compared with that of other substances, the degradation of glucose by *A. aerogenes* has one unusual feature. Glucose is metabolized under aerobic conditions at a rate which is at least double that commensurate with the growth-rate and total crop of cells; the extremely large amount of glucose metabolized during growth is reflected in the amount of labile ('high energy') phosphate present in the cells (Table 2). Additional information obtained in this laboratory indicates that the metabolism of glucose in the presence of inorganic nitrogen (NH_4^+) results in a plentiful supply of nitrogenous organic compounds. These results are in good agreement with the observation that vitamin, amino-acid and purine and pyrimidine supplementation fails to increase the growth-rate of this organism on glucose, while such supplementation does accelerate growth on other substances[3]. Cells growing on glucose, far from being deficient in the substances necessary for protein synthesis, actually possess these substances in excess. The uniformly negative results of past attempts to effect a reversal of the glucose inhibition by enriching the growth medium are thus understandable.

Table 2. SOME CHARACTERISTICS OF THE GROWTH OF *A. aerogenes* ON DIFFERENT SUBSTANCES

Substrate	Carbon uptake in μatoms/mgm. growth	Labile PO_4 in μmoles/mgm. cells*	(*k*)†	Rate of carbon uptake‡ μatoms/mgm./hr.
Glucose	110	12·2	1·26	139
L-Histidine	89§	7·7	0·59	53
Glycerol	58	2·1	1·00	58

* These experiments were done in collaboration with Mr. Fred Valentine.

† The growth-rate constant, *k*, is defined by the expression, $dC/dt = kC$, in which *C* is the turbidity of the culture in optical density units, and *t* is time expressed in hours.

‡ This was calculated by multiplying the carbon uptake (μatoms/mgm. growth) by the growth-rate constant (hr.$^{-1}$) of the cells on that particular substance.

§ L-Histidine is assumed to have five utilizable carbons. One of its carbon atoms is not metabolized, but excreted as formamide.

If we now consider the class of enzymes the formation of which is inhibited by glucose metabolism, an interesting generalization can be made: the 'glucose-sensitive' enzymes the biological functions of which are known furnish the cell with carbon-building blocks and energy (for example, enzymes degrading carbohydrates) or nitrogen (for example, amino-acid deaminases), that is, products also readily obtainable from the metabolism of glucose.

This generalization permits a clearer conception of the inhibition. It would appear that the levels of the metabolites resulting from intermediary metabolism control the synthesis of enzymes which form these metabolites, presumably by a system of feedback mechanisms. The existence of analogous feedback mechanisms controlling biosynthetic reactions has already been indicated[5], and in some cases it can be shown that the actual formation of a biosynthetic enzyme is inhibited by the presence of the final product of the reaction sequence[6]. Thus, certain biosynthetic enzymes, too, seem to be formed only when their products supplement the composition of the growth medium, not when they augment it. Glucose is metabolized so rapidly by an enzyme system always present in the cells that its intermediary products (carbon, nitrogen and energy in forms available for synthetic purposes) are formed faster than they can be removed by anabolic reactions. This accumulation seems to prevent the synthesis of enzymes the products of which would only augment the already large metabolic pools.

This work was supported in part by a research grant (*G*-3554) from the U.S. Public Health Service, by an institutional grant to Harvard University from the American Cancer Society, and by funds received from the Eugene Higgins Trust.

A New Embedding Medium for Electron Microscopy

THE introduction of *n*-butyl and methyl methacrylates as embedding media[1] constituted an important development in the preparation of ultra-thin sections of biological material; but their use is attended by various major difficulties. Shrinkage occurs on polymerization, hard objects are not penetrated by the monomer so that the plastic shrinks away and does not provide sufficient support, and sometimes there is an unaccountable appearance of bubbles around the specimen. Moreover, the polymerization process is not uniform and sometimes causes severe damage. This is perhaps most strikingly seen in bacteria where often only empty remnants of cell walls remain.

Attempts have been made to minimize these distorting effects by modifying the methacrylate procedure[2], but only with partial success. The substitution of a different embedding medium seems desirable. The possible usefulness of the epoxy resins for the preparation of ultra-thin sections of bacteria has already been indicated[3].

We have examined a series of epoxy resins, supplied under the name of 'Araldite'*, for their suitability as embedding media. On the addition of a hardener, which is a liquid anhydride, the resin sets slowly without shrinkage to form a light-gold block. The viscosity of the mixture and the hardness of the final block can be controlled with a plasticizer, dibutyl phthalate, and the rate of hardening can be varied with an amine accelerator. By a suitable variation of these components it is possible to produce an embedding medium with the properties required for electron microscopy. Slightly different combinations will be found convenient for different types of specimen; one such combination is described here.

The components were measured into a graduated cylinder warmed to 48° C. to facilitate drainage and were mixed in the following order:

'Araldite' *M*	100 ml.
Hardener 964 *B*	100 ml.
Plasticizer	10 ml.
Accelerator 964 *C*	3 ml.

Although the mixture can be stored at 4° C. for several days we found it convenient to prepare it in quantities one-tenth of those indicated. After stirring, a clear, golden liquid resulted which was more viscous than methacrylate monomers; but the viscosity could be reduced by holding the solution at 48° C. and infiltrating the specimens at this temperature.

In the preliminary trials the 'Araldite' mixture has been used for embedding bacteria, fragments of lung and mature hair fibres. After fixation and dehydration the specimens were soaked for 1–2 hr. in a 50/50 mixture of alcohol and 'Araldite'. They were then transferred to pure 'Araldite' for 2–3 hr. at 48° C., and finally placed in No. 00 gelatin capsules with fresh 'Araldite'. Curing for 48 hr. yielded a light-gold block with a hardness comparable with methacrylate.

The 'Araldite' had excellent cutting characteristics; sections were floated on to 20 per cent acetone–water, mounted on carbon films and examined in the electron microscope. Their electron density was similar to methacrylate. As had been hoped, bacteria were intact, and hair fibres were sufficiently well supported to allow thin sections to be cut and details of internal structure to be revealed.

It is considered that such an alternative embedding medium will be valuable for studies of tissue fine structure; but the resin must be tested on many different types of specimen before its potentialities can be fully assessed.

We are indebted to Dr. V. E. Cosslett and Mr. R. W. Horne, of the Cavendish Laboratory, Cambridge, for providing electron microscope facilities. One of us (G. E. R.) would like to thank the Commonwealth Scientific and Industrial Research Organization, Australia, for a studentship.

Re-appraisal of the Evidence for the Metabolic Conversion of Vasopressin into a Less Active Derivative

THE intermediary metabolism of peptide hormones is unknown, and it is therefore of great interest that Dicker and Greenbaum[1] have recently suggested "that both kidney and liver slices transform vasopressin into substances of lower antidiuretic activity". They reached this conclusion because they found that the activity of 'Pitressin', when incubated with rat kidney slices, decreased until 20 per cent of the initial antidiuretic potency remained; thereafter, there was no further inactivation. When the resultant supernatant from such an incubation mixture was added to fresh kidney slices its activity remained constant although it could be completely abolished by liver slices. Thus, the property by which Dicker and Greenbaum distinguish between vasopressin and the product of its metabolism is that the latter resists inactivation by kidney slices while vasopressin does not.

The results of *in vitro* experiments do not necessarily apply to the fate of vasopressin *in vivo*, but Dicker and Greenbaum attempted to show that, following intravenous infusion of vasopressin into rats anæsthetized with ethanol, the metabolic derivative of vasopressin is excreted in urine. After infusing large amounts of vasopressin they found that the antidiuretic activity excreted in urine was within the range found in previous investigations (3·1–22·0 per cent of the dose infused[2]). However, when urine containing this excreted activity was infused into another rat, they claim that 48–59 per cent of the dose now appeared in the urine. The explanation offered is that liver and kidneys *in vivo* treat vasopressin and the antidiuretic activity in urine as do slices of these organs.

Table 1. EXCRETION OF ANTIDIURETIC ACTIVITY IN URINE

	Per cent of dose recovered from urine	
	'Pitressin' infusion (200–400 mU./rat)	Infusion of urine secreted during and following 'Pitressin' infusion*
	4·8	13·8
	20 0†	10·4†
	5·1†	6·0†
	5·4	11·0
Mean	8·8 ± 3 7 (S.E.)	10·3 ± 1 6 (S.E.)

* The urine was adjusted to plasma osmoticity.
† Results obtained in rats anæsthetized with ethanol.

Accordingly, half the infused urinary antidiuretic substance would be destroyed in the liver while the remainder would pass through the kidneys unchanged.

We have been engaged in the study of the fate of vasopressin for some years[3-6], and in continuing this work it was necessary to follow up Dicker and Greenbaum's interesting hypothesis. We have therefore repeated their *in vivo* experiments. We found that in rats infused with 'Pitressin' the urine secreted during the period of infusion (1 hr.) and during the subsequent hour had antidiuretic activity equivalent to between 4·8 and 20·0 per cent of the dose. In rats into which this urinary antidiuretic activity was infused, the urine contained between 6·0 and 13·8 per cent of the antidiuretic activity infused (Table 1). That is, the urinary antidiuretic activity was excreted in the same proportion as was 'Pitressin'. These experiments were performed on both conscious rats and on rats anæsthetized with ethanol.

The transformation of vasopressin *in vivo* into a less-active metabolic product remains a possibility; but the experimental evidence upon which this hypothesis was based cannot be confirmed.

Protective Action of Vitamin B_{12} in the Hyperthyroid Rat

THE protection afforded by vitamin B_{12} against thyrotoxicosis in the rat was explained as due to a restoration in part of the uncoupling of oxidative phosphorylation caused by thyroxine[1]. Since it is known that osmotic damage to mitochondria could cause a diminution in oxidative phosphorylation[2], the possibility was considered that in hyperthyroidism there may be an altered distribution of vitamin B_{12} in the cell fractions.

The basal diet employed was a purified casein ration[3] with vitamin additions including folic acid (3 mgm./kgm. of diet). Groups of six to eight male rats (Wistar strain), 50 gm. in weight, were fed this vitamin B_{12}-free ration with modifications as shown in Table 1. Iodinated casein ('Protomone': Cerophyl Laboratories, Kansas City, Mo.) was added to the diet at 0·3 per cent level. Vitamin B_{12} was given intraperitoneally at 10 gamma/rat on alternate days. All animals were killed at the end of five weeks when those of group 3 showed distinct symptoms of hyperthyroidism. Blood was withdrawn by venipuncture after phenobarbitone anæsthesia, immediately citrated and an aliquot centrifuged for plasma. Livers were excised, chilled in cracked ice and a 20 per cent homogenate prepared in ice-cold isotonic (0·25 *M*) sucrose; an aliquot was used for centrifugal fractionation[4], particulate fractions being carefully washed with sucrose solution.

Vitamin B_{12} in all samples was liberated by overnight incubation under toluene with papain (B.D.H.) using 25 mgm./gm. of liver or per c.c. of blood or plasma, in acetate buffer of *p*H 4·6 [5]. The samples were then autoclaved, homogenized, neutralized and made to volume. Assays were made with *Lactobacillus leichmannii* (ATCC 7830) by a turbidimetric adaptation of the U.S.P. method[5]. All results are averages for at least four animals in each of the groups.

It may be seen (Table 1) that in the hyperthyroid rat there is a marked fall in the concentration of vitamin B_{12} in the circulating blood and in the percentage retained in the blood cells; this is prevented by vitamin B_{12} administration. A similar fall in liver and mitochondrial vitamin B_{12} of thyrotoxic animals is also corrected by feeding the vitamin. However, in the latter case, there is a rapid uptake of the vitamin which resides largely in the nuclear and supernatant fractions. It has been observed that the values for vitamin B_{12} in these two fractions return to normal levels when iodinated casein is withdrawn from the diet.

The pronounced lowering of liver and its mitochondrial vitamin B_{12} in hyperthyroidism parallels the known decrease of liver pyridinonucleotides and of their percentage linked to mitochondria[6]. It is also consistent with other observations (unpublished data) on the more rapid *in vitro* release into the surrounding medium of the intramitochondrial nucleotide components[7] from livers of thyrotoxic rats. Since the synthesis of adenosine triphosphate is rendered inoperative as a result of structural damage to mitochondria[2], the observations on the protective action of vitamin B_{12} against thyrotoxicosis[1] seem explicable on the basis that vitamin

Effect of Orotic Acid on Vitamin B_{12}-deficient Rats

Studies in this laboratory[1,2] have recently shown that orotic acid is a factor for growth and survival in rats depleted of the animal protein factor of casein. Also, vitamin B_{12} has a protective effect on the deficiency in animal protein factor[3]. This indicates a relationship, from a nutritional point of view, between vitamin B_{12} and orotic acid. In the present communication the direct influence of orotic acid upon the deficiency of vitamin B_{12} is reported.

To this end, thirty-six weanling rats, male and female in equal number, of the Sprague–Dawley strain weighing 40–45 gm. were employed. The animals were divided into three groups, all of which were fed the basal vitamin B_{12}-deficient corn–soybean meal ration proposed by Register *et al.*[4], namely, whole ground yellow corn 46·35 gm., commercial soybean meal 46·35 gm., corn oil 5 gm., cystine 0·3 gm., calcium hydrogen phosphate 0·92 gm., calcium carbonate 0·6 gm., sodium chloride 0·44 gm., crystalline manganese sulphate 0·04 gm., thiamine 0·3 mgm., riboflavin 0·3 mgm., niacin 2 mgm., pyridoxine 0·2 mgm., pantothenic acid 2 mgm., folic acid 0·025 mgm., biotin 0·01 mgm., inositol 10 mgm., choline 100 mgm., *p*-aminobenzoic acid 25 mgm.; vitamins A and D were administered weekly. Iodinated casein or desiccated thyroid were omitted.

Group 1 served as control and received only the basal ration. Group 2 were fed the basal ration supplemented with vitamin B_{12} (2γ/100 gm. of diet). Group 3 received the basal ration supplemented with orotic acid (1,000γ/100 gm. of diet).

The animals were maintained on their respective ration for 4 weeks; at the end of this period weights were recorded and the liver betaine–homocysteine transmethylase activity was determined, on 6 animals for each group, by the method of Williams *et al.*[5]. It is known, in fact, that in vitamin B_{12}-deficiency growth is retarded, and the liver betaine–homocysteine transmethylase activity is decreased[5].

Table 1

Group No.	Supplement to 100 gm. basal ration	Body-weight after 4 weeks (gm.)	Transmethylase activity, γ methionine formed per hr. per gm. liver
1	None	95 (77–113)*	300 (288–322)*
2	2γ vitamin B_{12}	120 (104–155)	510 (425–580)
3	1,000γ orotic acid†	117 (107–133)	440 (383–517)

* Range of individual values.

† Orotic acid manufactured by Biochemical Inc., Co., Cleveland, Ohio.

The results are shown in Table 1.

From these results it appears that orotic acid has a growth-promoting action on the B_{12}-deficient rats; moreover, orotic acid is a factor stimulating liver betaine–homocysteine transmethylase activity.

These data suggest a metabolic relationship between orotic acid and vitamin B_{12}.

Glass Surface and Blood Coagulation

Platelet-free, citrated plasma, collected and handled in silicone-treated apparatus, has a very long clotting time on recalcification. The exposure to glass surface greatly shortens the clotting time, and various hypotheses have been advanced to explain this phenomenon[1–4]. The present study is an attempt to examine certain aspects of this reaction by the exposure of various normal and pathological plasma specimens and plasma fractions to a standard glass surface in the form of glass 'ballotini' spheres of 0·12 mm. average diameter. The activity may be assessed either by recalcifying the activated specimen directly or by adding a sample to a standard volume of silicone-collected plasma and recording the recalcified clotting time of the mixture. The use of this silicone plasma as a diluent is essential for testing samples which are devoid of one or more clotting factors (cf. Table 1). (For reasons to be discussed elsewhere, in some experiments 'silicone plasma' containing 2,000–10,000 platelets/c.mm. was used as the diluent for the activated, platelet-free samples.)

The results of such experiments are shown in Table 1, and it will be seen that the ability to respond to glass contact is not lost after heating at 56° C. or after absorption with aluminium hydroxide and is retained in the 30–50 per cent saturated ammonium sulphate fraction. These properties suggest that the substance concerned is not identical with any known plasma-clotting factor. The activation by glass contact could also be demonstrated in hæmophilic and christmas disease plasma and in the plasma of patients treated with dindivan, which indicates that the factors deficient in these samples cannot be directly concerned with contact activation. By adding small samples of glass-contacted plasma or fractions to platelet-rich plasma in siliconed containers, the prothrombin consumption of the latter was found to be markedly increased and thrombin generation greatly accelerated. These findings are consistent with past observations, based on different methods of approach[4–6]. Control samples of the

0·2 ml. of glass-activated samples or of their mixtures with silicone plasma were recalcified with 0·05 ml. of 0 1 *M* calcium chloride at 37° C.

* The clotting times are strictly comparable only within each individual experiment, that is, horizontally.

† Denatured fibrinogen precipitate was removed by high-speed centrifugation.

‡ Platelets (2,000–10,000/cm.) were deliberately added to the silicone plasma in these experiments.

substances, listed in Table 1, were not exposed to glass contact and had no effects comparable with the contacted specimens, showing that their activity was specific to glass contact and not incidental to the methods of preparation of the plasma fractions. The euglobulin fractions formed an exception to this rule and were apparently activated by the dilution procedure in the course of their preparation.

When plasma which has been exposed to a large glass surface is removed from contact with glass, its clotting time rapidly lengthens, showing that the activity is unstable. This sequence of activation – decay can be repeated; but the response is lessened with each repetition until the plasma is 'exhausted' and will not clot in glass. On the other hand, heated plasma or the fractions in Table 1 are much more stable in this respect, when incubated alone, but will still rapidly lose activity when mixed with untreated plasma. A heat-labile inhibitor system in plasma would account for these findings. If such an inhibitor is related to that described by Fiala[3] it would make it difficult to accept his hypothesis, according to which the shortened clotting time of plasma exposed to glass and other surfaces is due to the absorption of an inhibitor by these substances.

The most plausible explanation of the present findings is that an active substance is liberated from a precursor at the glass-plasma interface and is afterwards rapidly destroyed by an antagonist. The actual level of activity under any given contact conditions would then represent a dynamic equilibrium between these two opposite effects, the precursor being continuously exhausted at a rate which depends on the contact area, temperature, etc. A better understanding of the kinetics of this phenomenon will help to control an important variable in coagulation tests and thus increase their sensitivity and accuracy. For example, platelet-free plasma from dindivan-treated patients has been found to have a consistently prolonged coagulation time when recalcified under standard contact conditions (for example, with glass powder, or as in Table 1). Quantitative aspects and methods of measurement of the reactions described will be discussed in a further communication.

In a wider sense the 'contact' phenomenon may be of physiological significance as an initial stage of a general reaction to 'injury' (cf. the "pain producing substance"[7]) of which blood clotting is only one, rather late, evolutionary offshoot. The final formation of fibrin clot may, nevertheless, provide a very convenient indicator for the study of such early injury reactions the effects of which are by no means limited to coagulation.

I wish to thank Dr. R. G. Macfarlane and Dr. Rosemary Biggs for their generous advice and valuable criticism in the course of this investigation. The work was supported by a grant from the Royal Australasian College of Physicians and by the Sister Sanders Scholarship, University of Sydney.

Pharmacological Effects of Certain Diaminodiphenoxy Alkanes

A SERIES of diaminodiphenoxy alkanes was found independently by Raison and Standen[1] and Collins, Davies and Hill[2] to possess high schistosomicidal activity. Hill[3] has described in detail the therapeutic effects of one of these compounds in comparison with lucanthone (Miracil *D*), which is used in the treatment of bilharzia, and found that in mice the compound 1 : 5-di (*p*-aminophenoxy) pentane dihydrochloride (M. and B. 968*A*) was more active than lucanthone. The relative therapeutic indices were 3·3 (*LD*50 = 0·62 mgm./gm., *CD*50 = 0·19 mgm./gm.) and 0·9, respectively, and it had a more rapid action in clearing the mice of the schistosomes.

While the pharmacology of this compound and other active compounds was being studied, we encountered a toxic effect on the eye. This precluded the clinical use of this particular compound, though other compounds which retained therapeutic activity, yet were sufficiently devoid of this toxic action, will be described elsewhere.

On the oral treatment of monkeys, infected with *S. mansoni*, with daily doses of 100 and 200 mgm./kgm. of M. and B. 968*A* for four days, temporary impairment of vision occurred. This was obvious from their abnormal feeding behaviour—they could not readily see or focus on the food presented to them—and a marked dilatation of the pupils, which did not constrict to strong illumination either so readily or to the same extent as a normal eye.

Investigation showed that vision was impaired in some species, but not in others. The mouse, rat, guinea pig, rabbit and ferret were insensitive to single oral doses up to 400 mgm./kgm. (about two-thirds of the mean lethal dose in the mouse). On the other hand, the monkey, dog and cat were highly susceptible. In the cat, the species chiefly studied, single doses of 100–400 mgm./kgm. by mouth or by subcutaneous injection, or 25–50 mgm./kgm. given intravenously, caused loss of the blink reflex and marked dilatation of the pupils with almost complete loss of the pupillary, light and near reflexes. Visual perception, as judged by the animals' behaviour, was also impaired within twenty-four hours. If the compound was acting centrally, all the optic centres would be affected, but this seemed improbable in the absence of other central nervous symptoms.

The instillation of eserine into an affected eye within a few days of treatment, or peripheral stimulation of the oculomotor nerve in decerebrate preparations, caused pupillary constriction, indicating that paralysis of the nerves and muscles responsible for constricting the pupil had not occurred. The mydriasis was not due to an atropine-like or ganglion-blocking type of action. It was therefore inferred that the compound was probably acting directly on the retina or optic nerve.

Ophthalmoscopical changes were first observed after about seven days and consisted in marked constriction of the retinal vessels with pallor of the optic disk; in two weeks there was some pigmentary disturbance which after eight weeks became the predominant feature, producing a fundus picture resembling retinitis pigmentosa. Though this effect on the eye was by far the most characteristic and important toxic aspect of the compound, it also caused vomiting in cats and dogs, when given orally, but no other serious toxic effects were observed.

The significant histological changes in the eye, described in detail elsewhere[4], were almost entirely confined to the retina, there being widespread injury to the outer layers of the retina with total or patchy destruction of the visual cells, and localized displacement of the outer nuclear layer of the retina with arcade and rosette formation. There was marked degeneration and proliferation of the pigment epithelium. Bipolar cells and ganglion cells were preserved. Histologically these changes most closely simulate those which follow the administration of sodium iodate[5-7], rather than those resulting from iodoacetate[7,8].

Test for Cross-linking of Linear Polymers

CERTAIN linear polymers which have been used as picture varnishes are known to become cross-linked by the action of light. It is important to us to find out whether this is likely to happen for any particular case, since the insolubility resulting from cross-linkage makes it impossible to remove the varnish by solvent action alone.

The method which has been developed requires only a small rectangle of the varnish film (4–9 mm.^2, 20μ thick), and can be completed within an hour. The fragment of film is attached near the bottom of a filter-paper strip with one or two drops of a suitable solvent from a micrometer syringe. The fragment is then leached by developing the strip as in paper chromatography, although in this case there is only one solvent phase, and lengthy equilibration is unnecessary. This solvent should be chosen from among the best for the polymer. A dye, absorbed preferentially by either polymer or paper, may be dissolved in it.

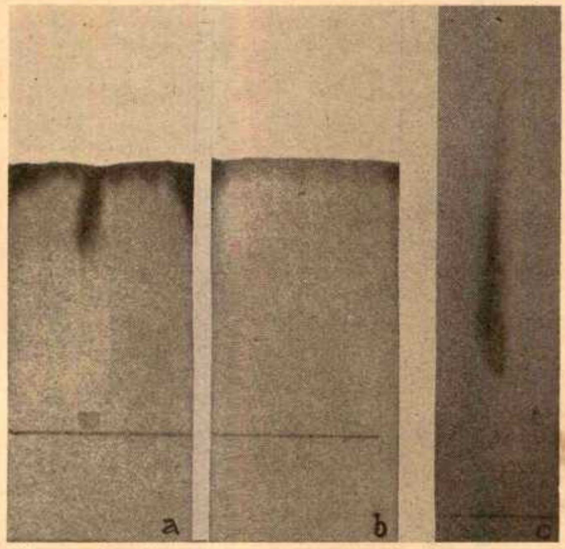

Fig. 1. Cross-linkage tests on 1-in. chromatography paper (Whatman No. 1). Origins are marked by horizontal pencil lines: the varnish fragments were placed just above these lines in (*a*) and (*c*). Solvent flowed upwards.
(*a*) A methacrylate polymer after being heated for 4 hr. at 155° C. Solvent and stain: benzene with 0·015 per cent sudan IV. (*b*) Blank strip for comparison. (*c*) Polyvinyl acetate after the same treatment as (*a*). Solvent: methanol. Light green was used as a paper stain so that leaching could be followed, but the resin was positively indicated by spraying with equal volumes of 5 per cent cerium nitrate and 0·1 *N* iodine

A long streak of soluble polymer moves along the paper so long as leaching continues, and ends fairly abruptly, to form a rounded tail, when all soluble polymer has been removed from the varnish fragment. The process is stopped as soon as the tail is clearly separated from the origin. Any polymer rendered insoluble by cross-linkage remains unmoved at the origin, so that the outline of the original fragment is sharply visible. This can be seen in Fig. 1(*a*), where a proportion of the polymethacrylate is cross-linked. The soluble portion forms a tail just behind the solvent front. Measurements by an interference method of the contraction in thickness suggest that about a third of the film has been rendered insoluble. Absence of resin at the origin in Fig. 1(*c*) indicates that none of the polyvinyl acetate has become cross-linked.

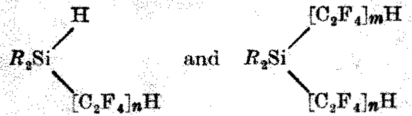
Free Radical Reactions with Inorganic Covalent Hydrides: a Route to Polyfluoroalkyl Silicon Compounds

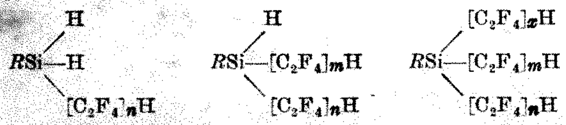
THE reactions of hydrocarbon free radicals are reasonably well established, but much less is known about the reactions of inorganic free radicals based on elements such as bismuth, silicon, germanium, lead, zinc, phosphorus, arsenic, tin or aluminium. The relative stabilities of some of these radicals can be predicted with reasonable certainty. The $SiCl_3$ radical, for example, should be similar in type to the CF_3 or CCl_3 radical, and it is not surprising that trichlorosilane reacts with olefins[1,2] to give $SiCl_3.[\text{olefin}]_n.H$; thus tetrafluoroethylene[2] yields $SiCl_3.[CF_2.CF_2]_m.H$, where $m = 1$–4.

Alkylsilyl radicals should be more reactive than trihalogenosilyl radicals, and a general study of their chemistry has been initiated. In particular, their reactions with olefins provide a useful new route for the synthesis of silicon compounds, and especially of polyfluoroalkyl silicon compounds.

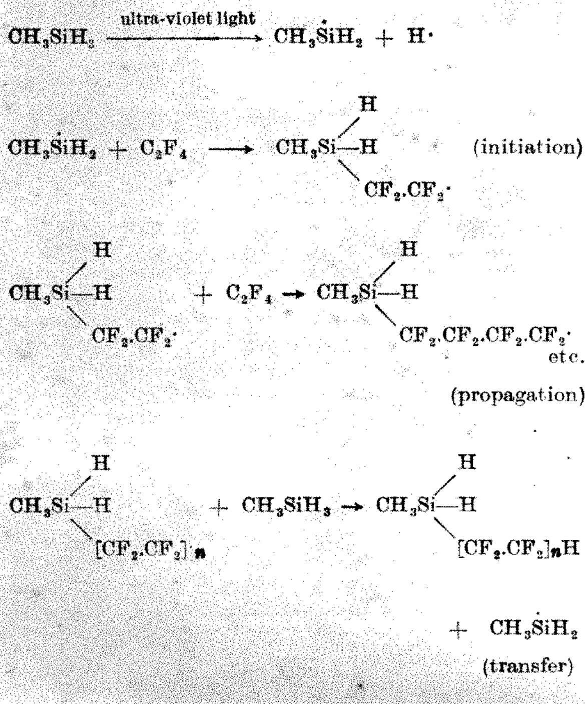
The free radical addition of a compound containing more than one Si—H bond to an olefin occurs with great ease. Thus with tetrafluoroethylene, dialkylsilanes, R_2SiH_2, yield the compounds



and alkylsilanes, $RSiH_3$, yield the compounds

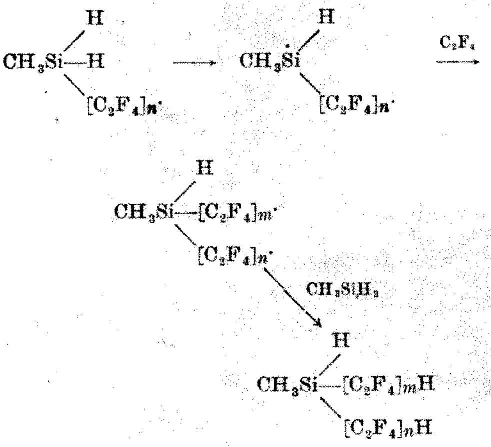


by very rapid quantitative chain reactions; for example:



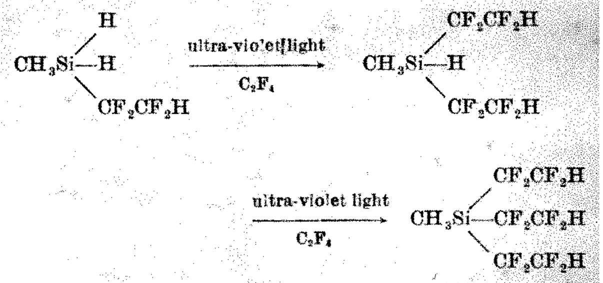
$CH_3SiH_3 \xrightarrow{\text{ultra-violet light}} CH_3\dot{Si}H_2 + H\cdot$
$CH_3\dot{Si}H_2 + C_2F_4 \longrightarrow$
CH_3Si—H
$CF_2.CF_2\cdot$
(initiation)
$+ C_2F_4 \rightarrow$
$CF_2.CF_2.CF_2.CF_2\cdot$
etc.
(propagation)
$+ CH_3SiH_3 \rightarrow$
$[CF_2.CF_2]_n\cdot$
$[CF_2.CF_2]_nH$
$+ CH_3\dot{Si}H_2$
(transfer)

The value of n can be controlled by the ratio of reactants used, and the compound where $n = 1$, for example, has been obtained in 63 per cent yield. It is noteworthy that under normal conditions the above propagation step proceeds in preference to initiation of new chains involving the second or third Si—H bonds:



Compounds containing more than one polyfluoroalkyl group attached to silicon are produced by the further reaction of the initial product $CH_3SiH_2[C_2F_4]_nH$ with tetrafluoroethylene; that is, mixed carbon–silicon di-radicals are not involved in the reaction.

The compound in which $n = 1$ can be made to react further with the same or a different olefin, so that a wide variety of silicon compounds can be obtained by this method; for example:



It is evident that such facile free-radical reactions are not restricted to silicon, and many other inorganic free radicals derived from covalent inorganic hydrides can be predicted to react with olefins such as tetrafluoroethylene. Compounds such as $P(CF_2.CF_2H)_3$, $Me_2BCF_2.CF_2H$, $MeAl(CF_2.CF_2H)_2$, $Me_3PbCF_2.CF_2H$, and $Zn(CF_2.CF_2H)_2$ should be capable of synthesis by this general method, although it is equally clear that certain of these will be stable only at relatively low temperatures.

'Acceleration' of Chemical Reactions

In a recent monograph on the thermodynamics of irreversible processes, Prigogine[1] has investigated in some detail the time variation of the entropy production (d_i^2S/dt^2). An examination of the implications of the general theory for the case of a chemical reaction leads to some interesting new concepts.

The entropy production at any particular time is given by

$$\frac{\mathrm{d}_iS}{\mathrm{d}t} = \frac{1}{T}Av \qquad (1)$$

where T is the absolute temperature, v the reaction velocity at that moment and A the instantaneous affinity defined as $-\sum\limits_i \nu_i\mu_i$ (ν_i is here the stoichiometric coefficient and μ_i the instantaneous chemical potential of the i^{th} component involved in the reaction). The coefficients ν_i are positive for products and negative for reactants.

On differentiation of equation (1)

$$\frac{\mathrm{d}_i^2S}{\mathrm{d}t^2} = \frac{1}{T}(A\dot{v} + \dot{A}v) \qquad (2)$$

where, in general, $\dot{v}$ and $\dot{A}$ represent differential coefficients with respect to time. We now propose to term the quantity $\dot{v}$ the 'acceleration' of a chemical reaction. This conception is valid only when the reaction velocity is not constant; otherwise, of course, $\dot{v} = 0$.

Utilizing Prigogine's theorem that the contribution to the rate of change of the entropy production per unit time by the rate of change of the generalized force' is equal to the contribution due to the 'acceleration', we obtain from equation (2)

$$A\dot{v} = \dot{A}v \qquad (3)$$

The reaction velocity v may be expressed as the rate of change of the 'degree of advancement' of the chemical reaction, ξ. Thus,

$$v = \frac{\mathrm{d}\xi}{\mathrm{d}t} \text{ and } \dot{v} = \frac{\mathrm{d}^2\xi}{\mathrm{d}t^2}$$

$\mathrm{d}\xi = \mathrm{d}n_i/\nu_i$, where n_i is the mole number of the i^{th} component.

The affinity A is a function of the variables of state p (pressure), T (temperature) and ξ. At constant pressure and temperature,

$$\dot{A} = \left(\frac{\partial A}{\partial \xi}\right)_{p,T}\frac{\mathrm{d}\xi}{\mathrm{d}t}$$

and equation (3) becomes

$$A\dot{v} = \left(\frac{\partial A}{\partial \xi}\right)_{p,T}v^2$$

Hence,

$$\dot{v} = \left(\frac{\partial \ln A}{\partial \xi}\right)_{p,T}v^2 \qquad (4)$$

It is this equation (4) that provides us with an explicit relation for the 'acceleration' of a chemical reaction.

In addition, Prigogine has established a general theorem which, for our purposes, may be expressed as

$$\dot{A} \leqslant 0 \qquad (5)$$

or by

$$v^2\left(\frac{\partial A}{\partial \xi}\right) \leqslant 0$$

However, since v^2 is always a positive quantity, the above relation implies that

$$\left(\frac{\partial A}{\partial \xi}\right)_{p,T} \leqslant 0$$

that is, the affinity decreases during the course of a chemical reaction and, at equilibrium, $A = 0$,—a result well known to workers in chemical thermodynamics.

Moreover, extending the foregoing theory, we find, from equations (3) and (5),

$$A\dot{v} \leqslant 0 \qquad (6)$$

and the 'acceleration' of a chemical reaction has, in general, the opposite sign to the affinity.

These results may easily be generalized to several simultaneous, accelerated reactions by following the usual methods as outlined by Prigogine.

To sum up: some of the basic properties of the newly defined 'acceleration' of a chemical reaction—equation (4)—have here been developed for those cases where Prigogine's theorems are applicable, that is, under certain restrictive conditions indicated in his work.

'Macrocrystalline' Carbon

From a mathematical analysis of the X-ray diffraction patterns of products obtained at various stages during the graphitization of carbon, Franklin[1], and later Houska and Warren[2], have shown that only two carbon interlayer spacings are possible: 3·35 A. for the orientated stacking in graphite, and 3·44 A. for the random orientation of the planes in carbon. Precise measurement of the interlayer spacing of cokes and carbons is not possible because of the very diffuse nature of the diffraction maxima, and it is therefore of interest to report that 'macrocrystalline' carbon with an interlayer spacing of 3·45 A. has been prepared by sublimation of artificial graphite under high vacuum. The material, as deposited, has a nodular surface with a grey metallic sheen. It has a low porosity, a hardness of between 1 and 2 on the Moh scale (compared with a value of less than 1 for graphite) and a true density of 2·22. The carbon content is greater than 99 per cent and the ash less than 0·4 per cent. The carbon planes of the individual crystallites are found to lie very approximately parallel to the surface on which deposition occurs, and the crystallite size, as shown by the sharpness of the lines in the diffraction pattern, is similar to that of artificial graphite. A diffraction pattern of this material together with patterns of graphite and a sample found to be a mixture of the two phases is shown in Fig. 1.

Contrary to expectation, this material did not graphitize readily. Prolonged treatment with strong sulphuric acid containing a little nitric acid had no effect, and temperatures in the range 2,800–3,000° C. were needed to convert a sample into graphite.

The hardness and stability of this compound suggest cross-linkage between the carbon-layer planes. Whatever form this linkage takes, the graphite layers must still be largely retained, and it must exist without introducing sufficient 3-dimensional order to give any general (*hkl*) reflexions. The method of preparation and purity of the compound make it necessary for the cross-linkage to be through carbon atoms, and some system similar to that suggested by Gibson, Holohan and Riley[3] may exist.

Effect of Fatigue Stresses on the Recovery Properties of Metals

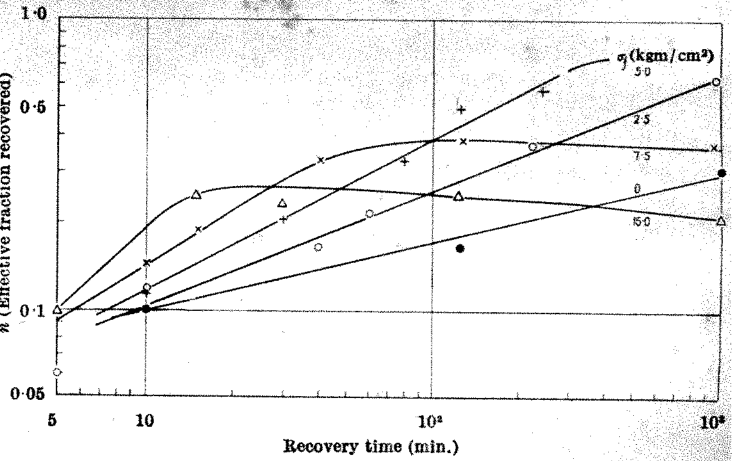

Fig. 1. Degree of recovery, represented by *n*, plotted against the recovery time for various levels of fatigue stress

In order to examine the nature of the interaction between the processes of creep, fatigue and recovery, some preliminary experiments have been conducted at room temperature on metals of low melting point. The tensile creep stress in these experiments was imposed by means of a mechanical spring system. The fatigue stress (also tensile) was applied by an electromagnetic vibrator and was detected and measured using a barium titanate crystal incorporated in the specimen grips.

A low-level sinusoidal fatigue stress (of about 300 c./s.) superimposed on the static creep stress increases the creep-rate of lead markedly. This phenomenon has already been observed by Greenwood[1]. In the present case, the measurements show that this increase is considerably greater than that resulting from applying the peak stress (static stress plus fatigue stress amplitude) statically. The most interesting results, however, are those which relate to the recovery processes. The investigation has been confined, to date, to the recovery of the transient creep properties during the unstressed period of an interrupted creep test. The degree of recovery that occurs may, of course, be deduced from the subsequent creep behaviour on reloading. All the specimens were subjected to a fixed amount of creep, under fixed conditions of stress and temperature, prior to the recovery period (ρ). The stress conditions applied during this period were varied, for the different tests, and an index of recovery, *n*, was deduced from the subsequent creep curve. The use of this index has been demonstrated elsewhere[2]; it is sufficient to say here that it represents the magnitude of the transient creep component on reloading by expressing this as a fraction of the original component for the fully annealed metal. Thus if the original transient creep is expressed in the usual power-law form by $\varepsilon = \beta_1 t^m$, where ε is strain and t the time, β_1 and m being constants, and if the 'recovered' component, exhibited on reloading, is given by $\beta_2 t^m$, then $\beta_2/\beta_1 = n$.

The results of a series of experiments on lead are given in Fig. 1. If no fatigue stress is imposed during the recovery period, we obtain a linear relationship between log *n* and log ρ, with a slope of about 1/3. This is in accord with previous work[2]. As the fatigue stress is increased, the rate of recovery at first increases; but eventually a second process, which has the characteristics of hardening, occurs. This slows up, or reduces, the total recovery observed. At higher fatigue stresses, the metal either fails by fatigue during the recovery period or fails shortly after reloading. The acceleration of recovery by the fatigue stress is similar to that observed in copper and other metals, using hardness as an index[3]. No previous observations appear to have been made on the transient creep recovery. This also appears to be the first observation of a 'mechanical re-hardening' under fatigue stresses.

Any adequate theory for these observations must take account of these two broad effects, acting in opposition. The present state of dislocation theory offers a reasonable basis for their interpretation. This may be very briefly summarized as follows. Dislocation jogs are formed by the intersection of dislocations during the creep process. These jogs, in motion, can generate vacancies (or interstitials). Such generation occurs, therefore, under the alternating stresses during the recovery period. The increased number of vacancies generated increases the probability of their diffusion to dislocations, and hence the probability of dislocations climbing. The rate of polygonization, which is controlled in part by the climb process, is therefore accelerated. This, then, is a possible mechanism for increased recovery. On the other hand, these same vacancies contribute to work-hardening by impeding dislocation motion, particularly when they form clusters, and over prolonged times this second process reduces the effects of the first. Ultimately the metal fails in fatigue by the growth of a crack initiated from a vacancy cluster, probably aggregated by dislocations acting as carriers.

It is interesting to compare results obtained in a very different field[4]. An initial softening of sodium chloride single crystals irradiated by 50-kV. X-rays was followed by a hardening over very prolonged times. This appears to be similarly explicable in terms of the vacancies created by the irradiation.

Flow-Birefringence and Stress

IN a recent communication[1], Dr. A. S. Lodge proposed: (*a*) to equate the extinction angle χ in flow-birefringence with the direction of the principal tensile stress, and (*b*) that the degree of birefringence Δn is proportional to the magnitude of the difference of the principal tensile and compressive stresses ΔP. For *plane* simple shear, $\Delta P \times \sin 2\chi = 2\tau$ or $\tan 2\chi = 2\tau/(\sigma_x - \sigma_y)$, where τ is the measured shear stress, $\sigma_x - \sigma_y$ the difference in 'normal stresses', both of which can be derived by various methods, for example, using Mohr's circle[2].

Lodge mentioned the possibility of the experimental proof of this assumption by simultaneous measurements of both the flow-birefringence and the normal stress $\sigma_x - \sigma_y$ $(= P_{11} - P_{22})$ using the Weissenberg rheogoniometer[3].

We investigated this possibility on a 15 per cent solution of *P*-100 poly*iso*butylene in decalin (maximum viscosity approximately 10,000 poises or a relative viscosity of $\sim 10^6$) at 30° and 50° C. in a range of rates of shear, D, from 0·007 to 4·5 sec.$^{-1}$. Three sets of experiments with separate instruments were run: (1) flow-birefringence tests, giving Δn and χ as functions of D; (2) 'flow curves' giving the shear stress τ as a function of D; and (3) 'normal stress' experiments giving $\sigma_x - \sigma_y$ as a function of D from measurements of the total thrust F, divided by the area (πR^2) of the plate in the cone-and-plate arrangement[4], $\sigma_x - \sigma_y = \dfrac{2F}{\pi R^2}$. We then made the following checks:

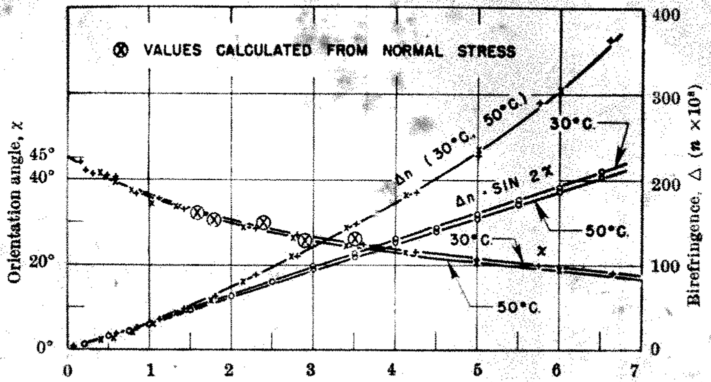

Fig. 1

(*a*) According to Lodge's assumption, Δn should be proportional to Δp for any solution, a relationship that was derived by Kuhn and Grün[5] and generalized by Treloar[6] for the stress-birefringence of highly elastic materials, such as rubber. As Lodge states, the identical relationship has been derived by Kuhn and Kuhn[7] for the flow-birefringence of an infinitely dilute solution of free-draining coiled molecules. As seen in Fig. 1, this proportionality is valid in the whole range of rates of shear investigated at both temperatures. The plot of Δn vs. τ proposed by Peterlin and Signer[8] is definitely curved upwards.

(*b*) The calculated values of χ from the normal stress measurements are plotted in Fig. 1 as circles: they check within 1° with the χ-values determined from the flow-birefringence experiments.

These checks show that the basic assumption of stress-birefringence of solids, that is, the proportionality of Δn and the difference of the principal stresses, is equally valid for the flow-birefringence of polymer solutions. The angle χ, giving the direction of the principal tensile stress, can be used to calculate the normal stress from the shear-stress and vice versa.

These checks probably will allow the well-developed results for the rheology of rubber (incompressible materials characterized by one shear modulus)—a 'continuum-mechanical theory' that has been summarized in Treloar's book—to be applied to the problem of the elasticity of flowing solutions of polymers, which have been treated hitherto by 'molecular theories'.

The proportionality constant, C, between Δn and ΔP:

$$C = \frac{\Delta n}{\Delta p} = \frac{2\pi}{45} \frac{(n^2 + 2)^2}{n} \frac{\alpha_1 - \alpha_2}{\kappa T}$$

depends essentially on the polarizabilities α_1 and α_2 of the monomer unit, which are calculable to some degree from the structural formula[9]. This would lead one to expect Lodge's result, namely, its independence of concentration of polymer and distribution of chain-length. Our values for $(\Delta p/\Delta n)T$ were $2{\cdot}14 \times 0{\cdot}10^7$ and $2{\cdot}04 \times 0{\cdot}10^7$ for 30° and 50° C. respectively, as compared with $2{\cdot}1 \times 10^7$ at 30° C. or $2{\cdot}3 \times 10^7$ at $-35°$ C. measured for solid poly*iso*butylene by Stein, Holmes and Tobolsky[10]; n for the solid polymer is approximately equal to that of the solution.

A comparison of the viscosity, η, at a given rate of shear, to the maximum value at low rates of shear, η_0, showed that the relationship proposed by Buchheim and Philippoff[11], namely, $\eta/\eta_0, = \sin 2\chi$, was not valid, η decreasing faster than $\sin 2\chi$ with D.

A check of the numerical evaluation of the theory of prolate ellipsoids published by Scheraga[12] showed that a proportionality between Δn and τ exists until

$$\alpha = \frac{\text{rate of shear}}{\text{rotational diffusion constant}} \approx 5, \text{ or until}$$

$\chi \approx 25°$, not the one between Δn and Δp. $\eta/\eta_0 = \sin 2\chi$ is valid in the whole range with deviation of only a few per cent. Whether this is a result of the assumptions in the mathematical theory or is due to a basically different mechanism of flow cannot yet be decided.

Further tests on the dynamic properties of the same solution (dynamic shear modulus and dynamic viscosity) over a wide range of frequency gave values not directly comparable with that calculated from the flow experiments, pointing to an obvious gap in the theory of such comparisons.

A more extensive publication will follow in the *Journal of Applied Physics*, following a paper presented at the meeting of the American Physical Society, High Polymer Physics Division, in Pittsburgh, Pa., on March 16, 1956.

Differential Sputtering of Grain Boundaries in Polycrystalline Tin

IT has been reported[1] that in a polycrystalline aggregate the properties of grain boundaries such as precipitation and chemical etching depend upon the difference in orientation of the adjoining grains. During our studies of cathodic sputtering of polycrystalline tin, we have observed differential etching from boundaries forming tricrystals[2]. Further work has shown that this differential etching can be correlated with the varying density of dislocation along the boundaries.

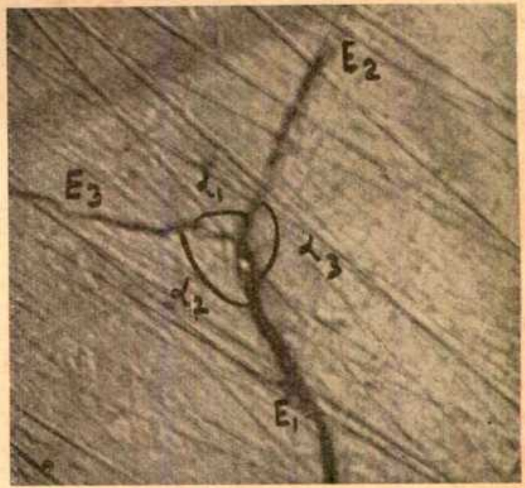

Fig. 1

A specimen of high-purity well-annealed polycrystalline (white) tin was polished mechanically. It was subjected to slow sputtering in a flushing atmosphere of argon (pressure about 0·1 mm.) employing the usual technique. The cathode–anode gap was 1·2 cm. and the applied rectified potential was 500 volts. Fig. 1 (× 100), showing a typical micrograph of the sputtered surface, is representative of a large number of results.

The dihedral angles, α, between the tricrystal boundaries were measured close to the junction within an accuracy of 1°. The relative grain-boundary free energies E were calculated by the expression

$$\frac{E_1}{\sin \alpha_1} = \frac{E_2}{\sin \alpha_2} = \frac{E_3}{\sin \alpha_3}$$

We have assumed the energy E_1 of the most etched boundary arbitrarily to be unity. The difference of orientation, θ, between the adjoining grains was obtained from Aust and Chalmers's data[3] for the grain-boundary energy vs. small angle of misfit for white tin. The Burgers vector b is taken as 5·831 A. Using the dislocation model of a simple grain boundary, the relative dislocation densities ($= \theta^2$ rad$/b^2$) along the tricrystal boundaries have been evaluated (see Table 1).

It is easy to see that the sputtering of the grain boundaries depends upon the density of dislocations, those with higher densities of dislocation having sputtered to a greater extent. The results support the 'transition lattice' theory of the grain boundary.

Thanks are due to the Council for Scientific and Industrial Research, Ministry of Education, Government of India, and the Scientific Committee, Uttar Pradesh, for support of the research schemes,

Table 1

Grain boundary	Opposite dihedral angles ($\alpha°$)	Relative boundary energies (E)	Relative difference in orientation ($\theta°$)	Relative densities of dislocation
Most etched	$\alpha_1 = 101$	$E_1 = 1{\cdot}000$	9·0	$7{\cdot}26 \times 10^{12}$/cm.^{2}
Moderately etched	$\alpha_2 = 117$	$E_2 = 0{\cdot}908$	6·6	3·90
Least etched	$\alpha_3 = 142$	$E_3 = 0{\cdot}626$	3·1	0·86

Influence of Trace Electrolytes on Interfacial Tensions at the Oil/Detergent Solution Interface

Recently, there has been some discussion between Brady, Pethica, Cockbain and others regarding the form in which the Gibbs adsorption isotherm should be applied to surface-active electrolytes in the absence of any added electrolyte. Under such conditions, and assuming complete dissociation of the surface-active electrolytes, it has been shown, for example[1], that the Gibbs equation (neglecting the correction for activities) may be written in the form

$$\frac{2kT}{A} = -c\frac{d\gamma}{dc} \qquad (1)$$

where γ is the interfacial tension; c the concentration of surface-active electrolyte; A the area occupied per film ion at the interface; k the Boltzmann constant, and T the absolute temperature. This has been verified by Cockbain[2] for sodium dodecyl sulphate at the oil–water interface. Other investigators, however, have found[3,4] that the form theoretically applicable in the case of excess added electrolyte, namely,

$$\frac{kT}{A} = -c\frac{d\gamma}{dc} \qquad (2)$$

appears also to apply in practice to the case of no added electrolyte.

While studying the interfacial tension behaviour of ionic detergents adsorbed at an oil (petroleum ether, b.pt. ~ 120° C.)–water interface a curious effect was observed, which may well reconcile these discordant results both with each other and with theory. Four systems have been investigated, namely, sodium dodecyl sulphate and dodecyltrimethylammonium bromide each in aqueous solution and in 0·1 *M* sodium chloride. Interfacial tensions were determined by a drop volume method.

The results for each detergent in 0·1 *M* sodium chloride appeared normal. Ageing was appreciable only at very dilute concentrations ($\sim 10^{-5}$ *M*). In aqueous solution, however, the results depended on the purity of the water used.

In the first series of experiments the aqueous solutions were made up with water from a standard Manesty still (specific conductance $\sim 4 \times 10^{-6}$ ohm^{-1} cm.$^{-1}$). Ageing effects extending over hours were observed with sodium dodecyl sulphate at all concentrations studied ($\sim 10^{-2} - 10^{-4}$ *M*) and with dodecyltrimethylammonium bromide at concentrations $\sim 10^{-3}$ *M*. This work was repeated using the same water redistilled from a glass still and freshly boiled to remove carbon dioxide (specific conductance $\sim 2 \times 10^{-6}$), but little improvement was noted.

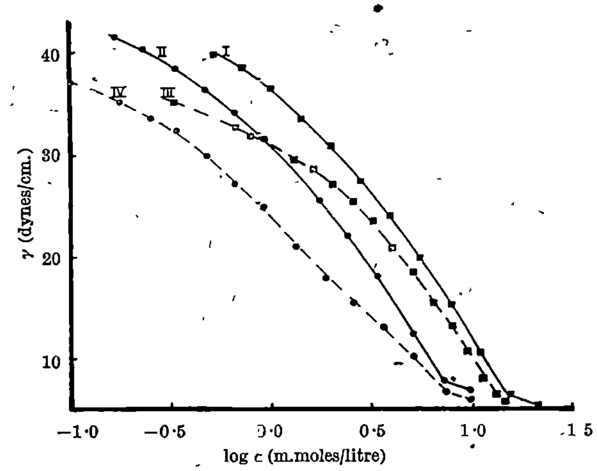

Fig. 1. Interfacial tensions of sodium dodecyl sulphate and dodecyltrimethylammonium bromide at the petroleum ether–water interface.
I, Dodecyltrimethylammonium bromide in water passed twice through a column of 'Biodeminrolit'; II, sodium dodecyl sulphate in water passed twice through a column of 'Biodeminrolit'; III, dodecyltrimethylammonium bromide in glass-distilled water; IV, sodium dodecyl sulphate in glass-distilled water

Finally, the Manesty-distilled water was passed twice through a column of ion exchange resin ('Biodeminrolit') and collected in polythene vessels (specific conductance $\sim 0{\cdot}9 \times 10^{-6}$ ohm^{-1} cm.$^{-1}$), no special precautions being taken to exclude carbon dioxide or ammonia present in the atmosphere. In this instance little ageing was observed except in very dilute solution, and the γ-$\log_{10}c$ curves obtained (Fig. 1) were found to be displaced from the original curves towards higher interfacial tensions at comparable concentrations.

Surface potential studies with dodecyltrimethylammonium bromide by us (which will be described elsewhere) permitted the surface area (A) occupied per film ion to be determined independently of the Gibbs equation, thus enabling the correct form of the Gibbs equation to be found. It was found that with glass-distilled water the 1.kT form (equation (2)) applied, while with ion-free water the 2.kT form (equation (1)) was appropriate. This suggests that glass-distilled water contains a swamping excess of electrolyte, but the conductivity values indicate this is not so. We must conclude, therefore, that this anomalous behaviour in normal distilled water is due to a specific adsorption at the interface of one or more trace counter ions present in the bulk, although no attempt has been made to determine the nature of these ions. Likewise, the long ageing effects can be attributed to the slow adsorption of the trace counter ions from the bulk of the solution.

Thus the disagreement regarding the appropriate form of the Gibbs equation to be applied to surface-active electrolytes in the absence of added electrolyte may be due merely to the purity of the water employed by the different investigators. In conclusion, it may be added that the results reported here for ionic detergents add to the extensive literature already available, for example, on the sensitivity of monolayers in general[5-9], and carboxylic soap films in particular, to trace electrolytes.

We wish to express our thanks to Sir Eric Rideal for many interesting discussions, and for the valuable suggestions arising therefrom.

'Continuous' Intensities in the Soft X-Ray Region

The generally accepted empirical law relating the intensity of the 'continuous' X-radiation with energy and atomic number, $I = kZV^2$ (for constant current), is known to apply to the 'hard' X-ray region; but its validity has never been established in the 'soft' X-ray region. The classical experiments which established it were done with deep ionization chambers; the integrated intensity over the whole band of emitted wave-lengths as well as the intensity at any arbitrary wave-length over the range were found to fulfil the above law approximately.

We have attempted to see how far this law was obeyed in the soft X-ray region using a 15-stage beryllium–copper photomultiplier in vacuum as detector, together with a d.c. amplifier as recorder of the total radiation emitted from the target. Our experiments were confined to two types of thick target—copper and carbon—over a range of energies from 200 V. to 8,000 V., that is, from thresholds of 62 A. to 1·5 A. respectively. Previous experiments with photographic plates had shown that 'background' radiation was emitted over a wide range of wave-lengths from the 'threshold' to well over 500 A.; this was superimposed on the characteristic soft X-radiation from the target. The latter occurs for copper at about 13 A. and 170 A. for the *L* and *M* bands respectively, while the *K* radiation of carbon was excited at about 45 A.

In order to avoid spurious results, the targets were bombarded at a red heat in vacuum for several periods of 15 min. each, before making observations; the surface, conditioned in this way, gave repeatable results over the time taken by the observations, which was generally a few minutes. The choice of working conditions was facilitated by having the target rotatable on a ground joint so that the angle of optimum intensity through the main and subsidiary slits (0·1 mm. and 5·0 mm. respectively) could be accurately set, to give a maximum of intensity for all the wave-lengths emitted into the photomultiplier. This is usually close to grazing incidence.

The procedure adopted was to apply a constant voltage to the target and vary the current, noting the d.c. output response. This was repeated over the whole range explored. All the results both from 'contaminated' and clean targets showed that for any fixed voltage the X-ray output is directly proportional to the current. However, for any fixed current, the output is approximately proportional to the *first* power of the voltage. This is illustrated in Fig. 1, where log intensity is plotted against log voltage for two different current values in the case of clean targets of copper and carbon. Except for the lowest energy points for carbon at 200 volts, the slope is about 1·15, so that in this region of soft X-rays, the 'square' law does not appear to be valid.

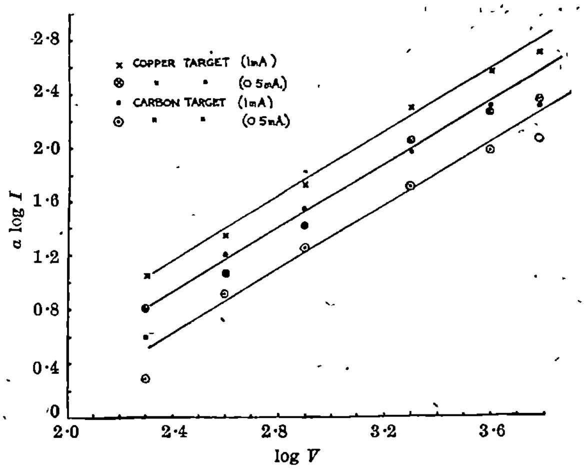

Fig. 1

It will also be seen that the dependence on atomic number is no longer given by the empirical relation, for the ratio decreases from about 3 at the lowest energy to about 2 for medium and high energies in the range chosen. It is hoped to publish fuller details at a later date.

Importance of Gas Spaces in the Propagation of Detonation of Granular Explosives

It has been suggested that in low- and medium-velocity detonation in condensed explosives, propagation may be due to heating in the shock front of gas entrapped in the explosive[1]. The temperature in these gas pockets has been shown to be very high[2], and the hypothesis is confirmed by the known effect of increase in gas pressure in stopping detonation in certain granular explosives[1]. The temperature attained in the gas depends on the compression ratio and the ratio of the specific heats of the gas, γ. If the hypothesis is correct, increase of γ should cause an increased temperature, and hence an increased rate of reaction, which should be manifested as an increase in the velocity of detonation of the explosive fired at cartridge diameters below that required for maximum velocity. We have now demonstrated this effect experimentally.

We have examined the effect of replacing air ($\gamma = 1{\cdot}40$) by argon ($\gamma = 1{\cdot}67$) as the surrounding medium on the velocity of detonation of two granular explosives. These were granular T.N.T. (Grade 1, 22–30 B.S.S.) of density 1·00 gm./cm.^{3} and cartridge diameter 1¼ in., and an 82/18 mixture of ammonium nitrate (specific surface 1,200 cm.^{2}/gm.) and aluminium (specific surface 1,600 cm.^{2}/gm.) of density 0·75 gm./cm.^{3} and cartridge diameter $\frac{7}{8}$ in. The velocity of detonation was measured photographically.

For the T.N.T. the velocity of detonation in air was 1,380 ± 20 m./s., and in argon 1,580 ± 15 m./s. For the ammonium nitrate composition, the velocities were 2,850 ± 30 m./s., and 3,100 ± 30 m./s., respectively, the limits quoted being standard deviations. There is clearly a significant increase in velocity, which further confirms the view that the mechanism of propagation of detonation involves heating of the gas spaces by the shock front.

Effect of Lightning Discharges on Magnetographs

Chaubal, Deshmukh and Malurkar[1] recently reported an instance of "minor oscillations" recorded particularly by the La Cour *H* and *D* magnetographs of the Alibag Observatory during a thunderstorm which passed over Alibag on June 2, 1955. They were interested to know if similar observations were available from other observatories.

Since 1952, two complete sets of photographically recording magnetographs, one Watson and the other La Cour, have been functioning regularly in the Magnetic Section of the Kodaikanal Observatory. During the past four years or more, in the thunderstorm seasons, I have often noticed in the traces of these magnetographs oscillations of precisely the same character as reported by Mr. S. L. Malurkar and his co-workers. I have always thought them to be caused by lightning discharges. However, I have now examined all our La Cour and Watson records from 1952 to date in order to check the correctness of the impression that these characteristic oscillations are of rather common occurrence and are indeed associated with thunderstorms. In our records there are some dozens of instances of such oscillations which correspond with thunder and lightning reported by our weather observer. There are also some instances in which similar, though usually less-marked, oscillations are noticeable, but no corresponding thunderstorms are recorded in the weather observer's diary. The cause of these latter oscillations is obscure; perhaps, during the normal watch hours the weather observer has not noticed the somewhat distant or minor lightning discharges, and presumably has not reported all the thunderstorms that may have occurred late in the night. It is also not impossible that some of the very feeble oscillations are due to the momentary, but heavy, direct current which the battery supplies to the self-starter of a motor-car engine starting up rather close to the magnetic observatory. However, in all cases in which there is correspondence between the magnetic oscillations recorded and the lightning reported there can be little doubt but that it is the short-duration electric currents accompanying lightning strokes which are responsible for the perturbations recorded by the magnetographs.

The variometer room at Kodaikanal is a very substantially built, thermally well-insulated chamber with a thick roof and heavy double walls of stone masonry. Both the Watson and La Cour variometers are installed on piers supported by the masonry floor in exactly the same manner. The sensitivity (taken to mean the ability to respond fully to a variation of duration comparable or greater than the period of the instrument) of the Watson *HF* instrument is considerably higher than that of the corresponding La Cour instrument. It does not seem that the method of mounting of a magnetograph has much to do with its capacity for recording the oscillations caused by impulsive lightning discharges.

From Kodaikanal records it is clear that often the magnetic oscillations due to lightning strokes occur simultaneously in all the three traces (*H*, *D* and *V*) of the La Cour variometers, although the amplitudes are different in the three components, evidently because the corresponding intensities are also different. We have many instances in which the Watson instruments (especially *H* and *D*, the performance of the *VF* instrument being often unsatisfactory) have also recorded such oscillations during thunderstorms; but these oscillations have smaller amplitudes than those recorded by the La Cour variometers, and are very much damped. These differences are evidently attributable to the fact that compared to the La Cour variometers the Watson magnetographs have considerably greater inertia and higher damping.

I am indebted to Mr. R. V. Subramanian for assistance in examining the magnetic records.

Vowel Sounds and Perceptual Constancy

IT has been known for some time that vowels are distinguished from one another mainly by the frequencies of the formants or regions of the auditory spectrum in which there is a comparatively large amount of energy. Recently, the hypothesis has been put forward by Joos[1] that when a listener identifies the vowel in a particular word he does so not by considering the absolute value of the lowest two formant frequencies, as was previously thought, but by assessing the frequencies of these formants in relation to the formant frequencies of other vowels which he has heard pronounced by that speaker. On this hypothesis, the identification of a particular sound depends on the acoustic structure of the neighbouring sounds.

A similar process is known to occur in the perception of other kinds of sensory data. Thus in visual experiments the same response, 'white', may be given to a piece of paper in sunlight and in an artificially lighted room, despite the wide differences in the spectra of the light reflected from the paper: the other neighbouring stimuli compensate for the differences[2].

It has recently become possible to demonstrate the auditory phenomenon with the aid of synthetic speech, which can now be precisely controlled and yet sound so natural that it is invariably confused with ordinary recorded speech. The instrument accomplishing this is the Parametric Artificial Talking Device of the Ministry of Supply Signals Research and Development Establishment. The sounds of most utterances can be specified in terms of six variables. Three of these are the formant frequencies: the other three are the intensity of the voicing; the intensity of the fricative noise which is present in some sounds such as *s*; and the fundamental frequency, which determines the pitch of the utterance. In the Parametric Artificial Talking Device, complex sounds are synthesized in accordance with the variations of these six parameters as functions of time.

In the current experiment, two versions of the phrase *Please say what this word is* were synthesized. The two versions were the same except in the range of their first formants, which were as shown in Table 1. Each version was followed by an identical test sound, which was a word of the form *b*-(vowel)-*t*. Recordings of these sentences followed by the test word were played to fifteen subjects, the playings being separated by at least five minutes. The subjects were asked to indicate whether the last word was *bit, bet, bat* or *but*. Fourteen of them reported hearing different words in the two cases, despite the identical physical stimulus. The experiment was repeated on fifteen different subjects, but with a ten-second silent interval between the introductory sentence and the test word. In this case only seven subjects described the words as different; the difference between the two groups is significant, $p < 0{\cdot}01$ by the exact treatment of a 2×2 table.

Table 1. DISTRIBUTION OF RESPONSES FROM THIRTY SUBJECTS

Preceding words with	Test word heard as *Bit*	*Bet*	*Bat*
First formant, 300–675 c.p s.	20	10	0
First formant, 150–400 c.p.s.	0	19	11

This establishes that there is an auditory parallel to the visual constancy effects cited earlier. Furthermore, the slight differences present in the auditory case may allow fresh experiments to reveal the mechanism of these constancy phenomena. Unlike the visual case, the auditory one allows interpolation of other voices, skewing of the distribution of preliminary stimuli, and similar experiments directed at comparing constancy phenomena with data on level of adaptation in psychophysics[3].

Finally, the experiment also demonstrates the value of a speech synthesizer, since comparable control of the stimulus could not be achieved using a live voice. The psychological and phonetic implications of these results are now being followed up in further experiments using synthetic speech.

"Automation Economics"

In his review of my book "The Economic Consequences of Automation" (September 1, p. 444), Mr. Austen Albu, while giving me credit for the originality of my argument on the inflationary effect of the pipeline-lag between input and output during periods of increasing production, accuses me of having contradicted my own theory. He states that the argument conflicts with my view that automation reduces the extent of inflation by raising the output of goods and reducing the need for labour.

Mr. Albu should have noticed, in my chapter entitled "Deflation or Inflation?", the following sentence: "It is our contention that, provided that there is an increase in the *aggregate* cost of production, the increase in the output is likely to be preceded by an increase in prices, even if there is a decline in the cost per unit" (p. 77).

The word 'aggregate' was italicized in the book. Had he noticed it, he could not possibly have attributed to me the categorical view that automation reduces the extent of inflation. It depends on how automation affects the aggregate cost of production as distinct from cost per unit of output. My attitude is defined even more clearly in the following passage: "In so far as the grand total paid out for raw materials, transport, wages, etc., is reduced [by automation] it results in a reduction in total income and consumers purchasing power, and should therefore tend to produce a deflationary effect. If, however, the total is increased, then the effect of automation will be inflationary even if the cost of production is reduced. . . . For during the 'pipeline-lag' described above, the volume of consumer purchasing power will increase without being accompanied by a corresponding increase in the volume of goods available to consumers" (p. 80).

Throughout the book I endeavoured to avoid answering with a dogmatic 'yes' or 'no' the large number of questions raised by automation in the economic sphere. I gave a list of influences working in favour or against inflation, deflation, unemployment, capital requirements, etc. A reviewer could easily single out apparently conflicting statements and accuse me of having contradicted myself; the only way in which I could have avoided this would have been by presenting only one side of the arguments. Instead, I prefer to rely on the judgment of those who will read my book with sufficient care to form a well-balanced opinion on it.

PAUL EINZIG

120 Cliffords Inn,
London, E.C.4.

If one accepts Dr. Einzig's view that all steps taken to increase production are inflationary, then the only distinguishable effect of automation is, as he says on p. 84, to reduce the extent of inflation. I think that the appearance of inconsistency arises out of the impression given by the title and some of the chapters that the book is about this mysterious concept 'automation'; whereas it is, in fact, a consideration of more general economic problems.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 15

Society of Chemical Industry, Pesticides Group (at 14 Belgrave quare, London, S.W.1), at 5.30 p.m.—Dr. J. A. Freeman: "Grain torage Problems".

University of London (at the Institute of Education, Malet treet, London, W.C.1), at 5.30 p.m.—Mrs. E. C. Mee: "Junior chool Education Today"*. (Second of eight lectures on "Problems f the Junior School". Further lectures on October 22, 29, November 5, 2, 19 and 26.)

Royal Institute of Chemistry, London Section (at the North-West Kent College of Technology, Miskin Road, Dartford), at 7.30 p.m. –Prof. A. R. Ubbelohde, F.R.S.: "Melting and Crystal Structure".

Tuesday, October 16

University of London (in the Anatomy Theatre, University ollege, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. J. Taylor: Machines and Men: The Nineteenth Century Background to utomation"*.

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 3 p.m.—Annual General eeting. Captain A. M. A. Majendie: "The Place of Navigation in odern Air Transport". (Presidential Address.)

Institution of British Agricultural Engineers (at the Royal ociety of Arts, 6 John Adam Street, London, W.C.2), at 4 p.m.—r. D. R. Bomford—John Fowler Memorial Lecture.

Institution of Chemical Engineers (at the Geological Society, urlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. ayler and Mr. H. R. C. Pratt: "Liquid–Liquid Extraction", Parts and 10; Mr. H. R. C. Pratt, Mr. L. E. Smith and Mr. J. D. Thornton: Liquid–Liquid Extraction", Part 11.

Royal Institute of Chemistry (at University College, Gower treet, London, W.C.1), at 5.30 p.m.—Dr. P. Gray: "The Chemistry f Dinitrogen Tetroxide". (Meldola Medal Lecture.)

University of London (at the London School of Hygiene and ropical Medicine, Keppel Street, Gower Street, London, W.C.1), t 5.30 p.m.—Dr. K. M. Smith: "The Electron Microscope in the tudy of Viruses*". (Second of fourteen lectures on "The Scientific asis of Medicine".)

Royal Institution (at 21 Albemarle Street, London, W.1), at p.m.—Dr. A. C. Menzies: "Optics in Industry". (Further lectures n October 23, 30, and November 6.)

Wednesday, October 17

University of London (at the Postgraduate Medical School of ondon, Ducane Road, London, W.12), at 2 p.m.—Prof. A. Neuberger: The Proteins of Connective Tissue"*.

Royal Meteorological Society (at 49 Cromwell Road, London, W.7), at 5 p.m.—Scientific Papers.

Royal Society of Medicine, Comparative Medicine Section t 1 Wimpole Street, London, W.1), at 5 p.m.—Dr. Douglas McClean: The Scientist as Citizen" (Presidential Address).

British Coal Utilisation Research Association (in the Lecture heatre, Institution of Civil Engineers, Great George Street, London, W.1), at 5.30 p.m.—Prof D. M. Newitt, F.R.S.: "Some Contribu-ons of Chemical Engineering to the Processing of Coal". (Fifth oal Science Lecture.)

Eugenics Society (at the Royal Society, Burlington House, iccadilly, London, W.1), at 5.30 p.m.—Symposium on "Artificial nsemination (Donor)"*.

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—r. R. C. G Williams: "The Electronic Age". (Chairman's Address.)

Royal Microscopical Society (at Tavistock House South, Tavi-ock Square, London, W.C.1), at 5.30 p m.—Dr. R. Barer: "Further evelopments in Quantitative Microscopy".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave quare, London, S.W 1), at 6.30 p.m.—Mr. M. A. Pearson: "Hydrazine a Corrosion Inhibitor".

Society of Chemical Industry (joint meeting with the London ection of the Royal Institute of Chemistry at the Institute of Metals, Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Mr. R. Llewelyn avies: "Design of Research Laboratories".

Thursday, October 18

University of London (in the Anatomy Theatre, University ollege, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. R. S yholm: "Magnetism and its Importance in Everyday Life"*.

Institution of Mining and Metallurgy (at the Geological ociety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—r. E. J. Pryor and Mr G. M. Lowe: "Changes in Copper Solubility uring Flotation of Malachite": Dr. J. M. Fletcher, Dr. D. F. C. orris and Mr. A. G. Wain: "Outline of a Solvent Extraction Process r the Purification of Niobium from Ores or from Ferroniobium".

Linnean Society of London (at Burlington House, Piccadilly, ondon, W.1), at 5 p.m.—Mr. Harry V. Thompson: "Myxomatosis nd the Rabbit in Britain"; Prof. H. R. Hewer: "The Method of ispersal of Animals".

University of London (at Goldsmiths' College, New Cross, London, S.E.14), at 5 p.m.—Prof. H. J. Eysenck: "Measuring Human Personality"*. (Second of six lectures on "Recent Pioneer Work in Education". Further lectures on October 25, November 1, 8 and 15.)

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. G. M. Binnie: "The Control, Storage and Use of Water". (Second of a series of six lectures on "The Conservation of Natural Resources".)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr F. H. C. Crick: "The Structure and Function of Small Viruses"*. (Third of fourteen lectures on "The Scientific Basis of Medicine".)

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m —Dr. P. J. Rigden: "Roads and Road Problems in South Africa".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, October 19

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Experiments for the Electronics Laboratory", opened by Mr. V. Attree.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1) at 6 p.m.—Mr. T. A. Crowe: "Motive Power on Sea and Land". (Presidential Address.)

Institution of Chemical Engineers, Graduates and Students Section (at Caxton Hall, Westminster, London, S.W.1), at 6.30 p.m.—"Impressions of the German Chemical Industry". (Conversazione on the Overseas Industrial Tour, 1956.)

Saturday, October 20

British Psychological Society (in the Psychology Department, Birkbeck College, Malet Street, London, W.C.1), at 2.30 p.m.—Dr. David Hamlyn: "Is a Theory of Perception Possible?"

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E 23), at 3.30 p.m.—Mr. Colin M. Turnbull: "Life in a Congo Village"*.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer, Grade B (honours graduate) in Physics at Brighton Technical College—The Director of Education, 54 Old Steine, Brighton (October 18).

Assistant Lecturer or Lecturer (with special interests in mineralogy and petrology) in the Department of Geology—The Registrar, University College, Singleton Park, Swansea (October 20).

Lecturer in Papermaking Technology—The Registrar, Manchester College of Science and Technology, Manchester 1 (October 20).

Biochemist, Senior grade—The Medical Superintendent, Stobhill General Hospital, Glasgow, N.1 (October 27).

Director of the Computing Unit—The Secretary of Faculties, University Registry, Oxford (October 30).

Assistant Experimental Officer (preferably with a degree in biology or at least H.S.C. or G C.E. to advanced level with biology or equivalent) at Merlewood Research Station, Grange-over-Sands, Lancashire, for work on soil invertebrates, including some field work—The Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S W.1 (October 31).

Assistants in Mathematics—The Secretary of University Court, The University, Glasgow (October 31).

Chair of Psychology in Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Lecturer in Psychology—The Registrar (Room 9, O.R.B.), The University, Reading (October 31).

Post-Doctoral Research Fellow in Organic Chemistry—The Secretary, The Queen's University, Belfast (October 31).

Principal (with high academic qualifications and appropriate educational and administrative experience in a University College or Technical College)—The Clerk to the Governors, Woolwich Polytechnic, London, S E 18 (October 31)

Ernest Canning Research Scholar (with a good honours degree in metallurgy, chemistry or physics, and industrial or research experience) for fundamental research in metal finishing—The Registrar, The University, Nottingham (November 3).

Soil Physicist (with a university honours degree in science (with physics as a major subject), together with evidence of research experience, preferably in the field of soil physics) in the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Adelaide, for research on the movement and measurement of water in soils—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 270/143 (November 3).

Chair of Chemistry in the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 8).

Lecturer or Assistant Lecturer in Chemical Engineering—The Registrar, The University, Leeds 2 (November 12)

Imperial Chemical Industries Research Fellow in Physics, Chemistry, Metallurgy, Engineering, or Geology, or in a subject allied to these—The Registrar of the University of Wales, University Registry, Cathays Park, Cardiff (November 15).

Lecturer (preferably with qualifications in one of the following: (*a*) first year teaching in botany; (*b*) algology, especially marine algology; or (*c*) cytology or cytogenetics) in the Department of Botany, University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, November 15).

Lecturer in Metallurgy—The Reader in Metallurgy, Department of Metallurgy, University Museum, Parks Road, Oxford (December 1).

Lecturers (3) and a Senior Lecturer in Physics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (Australia, December 15)

Analyst to assist with analysis of materials from animal feeding experiments—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Animal Husbandry Officer (with a university degree in agriculture and practical experience of livestock improvement programmes, especially cattle and pasture work, and preferably with tropical experience) in British Honduras, to be responsible to the Director of Agriculture for the Agricultural Department's livestock policy—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/31/06.

Assistant, Grade B (preferably honours graduate, with teaching, research or industrial experience) in Physics—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

Assistant Pathologist in the Department of Cancer Research—The Secretary, The London Hospital Medical College, Turner Street, London, E.1.

Chair of Physics in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Departmental Assistant (with a degree in agriculture and considerable practical farming experience) in Agriculture at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Head (with a good honours degree and experience in the direction and administration of metallurgical research, either academic or industrial) of the Metallurgy Division, the work of which is carried on in London and Sheffield and includes both fundamental and applied research in the general and physical metallurgy of iron and steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "H.M.D.".

Laboratory Technician to assist with research and class routine—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W 2.

Lecturer in Pharmaceutical Chemistry at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

Physicist to assist in physical and clinical work associated with X- and gamma-ray treatment and investigation—The Secretary, Physics Department, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3.

Physicists (2) or Applied Mathematicians (2) (with an aptitude for experimental work) for fundamental research and development work on the physics and mechanics of certain textile machines and processes; a Physicist or Mechanical Engineer for fundamental research and development work on the flow of fluids through textiles; and a Chemist for analytical work on the investigation of defects in textiles and on the development of new research methods—Dr. D. W. Hill, Director of Research, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester 20.

Principal/Senior Scientific Officer (with a first- or second-class honours degree in chemical engineering or chemistry, and/or A.M.I.Chem.E.), to lead a team concerned with chemical process development and plant design studies—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting A.1169/34

Research Student (graduate in chemistry or physics) for the study of flames by infra-red spectroscopy—Dr. G. J. Minkoff, Chemical Engineering Department, Imperial College of Science and Technology, London, S.W.7.

Scientific Officer (Chemist), Scientific Officer (Biologist), and an Assistant Scientific Officer in the Metropolitan Police Laboratory—The Secretary, Room 165 (S), New Scotland Yard, London, S.W.1.

Senior Lecturer in Market Garden and Glasshouse Crops—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex.

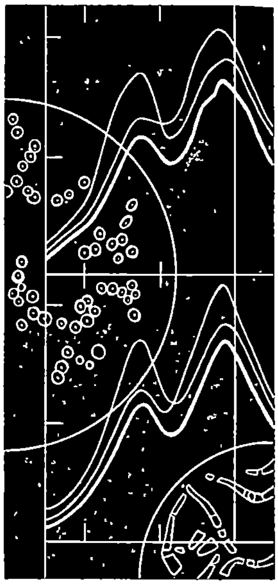
BOOKS ON SPECIALIZED SUBJECTS

Books on science, research, electronics, industrial work, electrical and mechanical engineering can be quickly supplied through your local Smith's shop or bookstall. College and works librarians and students, particularly, are invited to ask for lists of books on any subject. Any books not stocked locally will be quickly obtained from Head Office.



Your stationery and printed matter can also be supplied through our local branch.

FOR SCIENTIFIC BOOKS

Head Office. STRAND HOUSE, LONDON, W.C.2

The Analysis of Drugs and Chemicals

By **NORMAN EVERS, Ph.D., F.R.I.C.**
Editor · "Analytical Abstracts"

and **WILFRED SMITH, B.Sc., F.R.I.C.**
Chief Analyst, Messrs. Allen & Hanburys, Ltd.

This book includes monographs of a large number of new substances which are increasingly used in medical practice, food manufacture, agriculture, and in many branches of chemical industry. For works chemists, consulting analysts, and advanced students it will be indispensable.

540 *pages. Illustrated. Very fully indexed.* **60s. net**

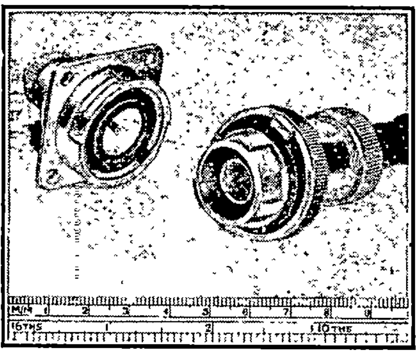
Exercises in Theoretical Statistics

By **M. G. KENDALL, Sc.D.**
Professor of Statistics, University of London

This collection has been produced to meet the need of graduate and post-graduate students for an extensive set of exercises of varying degree of difficulty. Answers and hints on solutions are included.

400 *exercises.* 179 *pages.* **24s. net**

CHARLES GRIFFIN & COMPANY LTD
Established 1820
42 DRURY LANE LONDON WC2



Plugs and Sockets for connecting screened coaxial cables

L 764 series incorporating free or fixed plugs and sockets and adaptor bulkhead.

Cable sizes 0.156″–0.312″ dia.

Splash-proof, polished light alloy housings with vibration-proof, quick-locking, retaining ring.

Hard gold plated contacts, removable to facilitate soldering.

Dielectrics: inner, polythene; outer, polystyrene.

Withstands Specification R.I.C.322 vibration tests.

For further particulars please apply to:

BELLING & LEE LTD

THE FINANCING OF UNIVERSITY RESEARCH

AT the second session of the Home Universities Conference a discussion on the financing of research in universities by outside bodies started from the data provided by a report on the relations between scientific research in the universities and ndustrial research in Great Britain which Dr. V. E. Cosslett had edited for the Association of University Teachers. It was several months, however, before the report was actually published* by the International Association of University Professors and Lecturers, with the assistance of the United Nations Educational, Scientific and Cultural Organization. n the meantime, in the debates on the Department of Scientific and Industrial Research Bill, both the control and adequacy of government research in Britain have come under fresh review, and in particular the adequacy of Government support of research in the universities was raised by Lord Cherwell. Prof. S. H. Beer's book on "Treasury Control", while concerned with the co-ordination of inancial and economic policy generally in Great Britain, raises some fresh issues in regard to the inancial control of research and of such activities as those of the universities, where accounting on a year-to-year basis may well lead to inefficiency and where he quinquennial principle has big advantages.

Since that book was published, a further report from the Public Accounts Committee has argued that mprovements in university procedure and methods affecting administration and contract practice are desirable in order to avoid waste and extravagance; and the preliminary estimates resulting from a survey of British investment in research and technical development made by the Department of Scientific and Industrial Research have been presented by Mr. Ernest Rudd in a paper to the British Association read at Sheffield on September 4. The figures were given in comparison with similar estimates for the United States and following the estimates made in the spring of last year by Sir Harold Hartley, and they raise once more the question of the adequacy of expenditure in Britain on research. Its distribution has also been challenged in connexion with the Department of Scientific and Industrial Research as well as, on occasion, in connexion with the development of nuclear energy and automation.

These three aspects of the national research spectrum cannot be sharply separated. If research—at the universities, in industry or in the government services—is not wisely directed, the effort is not likely to be distributed wisely, or if well distributed to yield the maximum return. If control is too rigid and exercised without regard to the nature of the work or the conditions in which scientific work s most fruitful, we are unlikely to attract the creative minds that are needed or to gain full advantage from the expenditure sanctioned. To devise the controls which provide the maximum freedom and stimulus for those engaged in research, and ensure that adequate resources are at their disposal, while at the same time seeing that the nation's available resources for research are deployed to the best advantage, so far as can reasonably be judged, and that there is no unjustifiable overlapping or waste, is a difficult task demanding judgment of a high order as well as insight and imagination and wide knowledge and experience.

The report of scientific research in universities and industry which was discussed at the Home Universities Conference shows how delicate is the balance, and it was obvious at that discussion that the universities themselves took a very wide public view of the problem. The report helps to supply the knowledge of the detailed ways in which university laboratories maintain direct contact with those of industrial laboratories which, apart from evidence obtained from industry in an inquiry made by the Manchester Joint Research Council, is largely lacking. After briefly outlining the organization of research in Great Britain, it describes the detailed relations of university and industrial research before considering the difficult problems which any great increase in the industrial research undertaken in university departments or by individual members of their staffs raises for the universities.

The inquiry was limited to research in the natural sciences, including engineering and technology, but excluding medical research. In these fields the inquiry showed that only 6 per cent of research projects in the universities undertaken by members of their academic staffs are financed wholly, and 32 per cent partly, from outside sources, and about half these projects appear to be initiated from outside sources. In all, about 20 per cent of the resources of scientific and technological departments in British universities are engaged on work of direct interest to industry, and this figure is equivalent roughly to 10 per cent of their total budgets and to 5 per cent of the university budget as a whole. This figure includes the support received from research associations, but not that received from other Government agencies, which may total another 7 per cent of the university income with a further 2 per cent coming from the charitable foundations, such as the Nuffield Foundation, and learned societies. Moreover, general opinion was overwhelmingly in favour of this contact with industry: 82 per cent of those replying thought it was of value to their own studies and only 23 per cent thought that it conflicted with their research interests; 86 per cent agreed that it was in the interests of the department as a whole.

This total of some 14 per cent of university income, however, represents about 25 per cent of the total income of the scientific and technological departments, and may amount to as much as 50 per cent of their funds for research. It should be noted that, in contrast to the position in the United States, most of these projects have been put forward on the initiative of the university worker. Apart from the present large pre-occupation with nuclear research, government grants to British universities have been primarily for fundamental investigations and are not related to immediate industrial needs, though this is not to say that in making a grant a research council may not have some longer-term national need in mind. The system, however, appears to be working well. But apart from these annual grants, the capital requirements of a university are likely to continue to be great, and even if private and industrial benefactions increase their support, the State will probably in future provide the major proportion of the capital as well as the current finance for university research.

---

* The Relations Between Scientific Research in the Universities nd Industrial Research: a Report on Conditions in Great Britain Edited by Dr. V. E. Cosslett. Pp. vii+187. (London: International Association of University Professors and Lecturers, 1956.) 15s.

Before considering the particular issue which caused most concern at the Home Universities Conference, the great variety of part-time, occasional and informal exchange of staff between industry and the universities should be noted. The usual method of getting specialist help from industrial scientists by university departments has been to appoint them as part-time lecturers. Direct interchange as yet is only on a small scale; but there has been a growing tendency since 1945 to increase the intercourse between industrial and university scientists, and the interchange of staff at all levels is a factor of the greatest importance in breaking down the tendency to look down upon industrial research. There are also many other varied ways in which intercourse between the universities and industry occurs in scientific and technological matters, and in general the report suggests that the universities should not be called upon to devote more of their resources to industrial problems. Some room for improvement may well remain, and in particular the relations of the universities to the research associations appear to merit closer examination.

While there are strong forces working against the establishment of closer relations between research associations and university departments, in preference to direct connexions between the latter and private firms, it has been argued that connexions between industry and the universities should be increasingly channelled through the research associations. This is quite apart from the educational functions of the latter, though those functions might be encouraged by such a development, which could well have the effect of ensuring that eminent university scientists are only called upon as consultants to industry for very specialized problems. On the other hand, the effectiveness of particular research associations as research organizations requires critical consideration before such a step is taken for any particular industry. On the basis of the general measure of support which industry gives to research, as indicated by Mr. Rudd's survey, little confidence can be felt that industry will simultaneously increase still further its benefactions to the universities.

The main problem at the present time arises from the increasing tendency during and since the War for government departments and industrial concerns to call on the universities for help in solving scientific and technological problems. This can result in the larger part of the research work of a particular university department being in the form of short-term contracts, and unless there is some degree of central control in a university, individual departments can in this way expand so as to throw out both the normal balance of research and teaching and that between fundamental and applied research. Even to devise appropriate methods of control within the university involves a number of delicate problems if the conditions for fruitful creative work are to be preserved. These are considered in the report, which seeks, however, rather to elucidate the principles that should guide policy and practice rather than to elaborate a precise system.

The report takes as the basis for a sound policy that a rough balance should be preserved between teaching and research in the university as a whole and in each department, and a similar balance between internally and externally financed research. As a first principle, adequate resources should be available within each university to finance the main lines of research in each department, so that appeals to outside bodies are for extension only and are never allowed to become a dominant and controlling factor. Universities best serve the community which supports them by undertaking fundamental investigation of natural phenomena rather than by working on problems of more or less immediate interest to industry. Accordingly, industrial and other private bodies can best support the universities by making unrestricted grants to their general funds, instead of earmarked grants for particular investigations or actual research contracts. The best place for applied research is usually the research association or the individual firm, and the report suggests that it would be well to accept as a limit for scientific departments that not more than one quarter of the total budget should be derived from outside sources.

The report does not consider whether or not applied research is appropriately carried on at the colleges of technology, though clearly the same considerations apply there as with the university departments of technology. Agreement, moreover, is desirable among universities as to the broad criteria to be used in assessing research contracts and the terms under which contracts would be accepted; and the proposals put forward in the report on the sponsored research policy of colleges and universities, prepared by a committee of the American Council on Education, are regarded as providing a reasonable basis for discussion. For those very large projects demanding installations so costly that they would seriously disturb the balance between a department and the rest of a university, the best solution is regarded as the establishment of a special research station with State funds which would be staffed and operated either by the State or by several universities in co-operation.

The difference in outlook between private industrial interests, with the natural desire to reap a quick advantage from priority in use, and the community of scholarship of the university is at the root of one of the chief arguments for strictly limiting the volume of research undertaken by universities and the conditions for acceptance. In time of peace, work carried out in academic laboratories should be free of restrictions on publication, and work involving ndustrial secrets should be carried out in industry itself, while secret work under government contract has only a place in a university under conditions of emergency and should be transferred to a State establishment as soon as facilities can be made available.

The report does not discuss exhaustively these and other problems which are causing increasing concern in the universities. But it stresses the need for wider recognition of the problems with which the universities and their scientific and technological departments are confronted in their relations with industry and with Government. It argues that more detailed official investigation is required if we are to work out solutions appropriate to the structure of research in Britain, and in particular suggests that we should develop still further the role of the research associations as a buffer, or filter between industry and the universities.

PAST ZOOLOGISTS AND PRESENT GENETICS

Portraits from Memory

Recollections of a Zoologist. By Prof. Richard B. Goldschmidt. Pp. x+181+4 plates. (Seattle: University of Washington Press, 1956.) 3.50 dollars.

Theoretical Genetics

By Prof. Richard B. Goldschmidt. Pp. x+563. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1955.) 64*s.* net.

PROF. RICHARD B. GOLDSCHMIDT, doyen of the genetical world and president of the most recent International Congress of Genetics, began his scientific life in Germany before genetics, as we know it, came to birth with this century. He can look back to a different era in zoology when the foundations were being laid for what have now grown into virtually new sciences; and he can recount personal reminiscences of men—the Hertwigs, Boveri, Roux and Spemann, to list but a few—who can be little more than names in books to most of us nowadays. In "Portraits from Memory" he looks back over the years and, with a wealth of delightfully told anecdote, brings to life for us this vanished world. We can sit in at a doctoral examination at Heidelberg, where the candidate attends resplendent, if uncomfortable, in tails and silk hat while professorial jealousies work themselves out; we can see the Kaiser fidgeting his way through a lecture by Richard Hertwig on sex determination; and we can share the triumph of the discovery of syphilis spirochætes and the heartache of its reception. At the end, names are mere names to us no longer. They are living men, brought to life by a portrayal of their foibles and jealousies as well as their talents and their greatness. We may feel that at times their pictures emerge in perhaps over-stark contrast of black and white, for one of the charms of the book is the way in which it relives Prof. Goldschmidt's own youthful enthusiasms; but our only regret can be that the portraits are not even more numerous. One reader at least would very much have liked to see Correns and Bauer, for example, through Prof. Goldschmidt's eyes, for portraits of the early geneticists are all too rare.

In "Theoretical Genetics" Prof. Goldschmidt turns to a totally different subject—the basic theoretical problems of genetics as he sees the science. It should be made clear at the outset that his coverage is by no means complete. Population genetics, genetic systems, chromosome mechanics, variability and selection, for example, are not dealt with. Rather, he concentrates on a discussion of the genetic materials and the way they do their work: on entities and processes at the cell-level. His approach is essentially physiological and developmental, and his treatment is, as we have come to expect of him, forthright and provocative. Nothing is left unchallenged, although one feels that the challenge is not always either effective or justified. It is generally accepted, for example, as the first principle of genetics that the phenotype is the product of reaction of the genotype and the environment. First, restating this to read ". . . that orderly development is the result of an interplay between genic activity and environment", Goldschmidt goes on to give his opinion that it "is a completely misleading statement in spite of its apparent truth", adding ". . . if we consider the organism within the environment to which it is adapted, development is completely controlled by the genic material". But surely, in the absence of any definition and criterion of adaptation, which is not supplied, this begs the question; and in any event, the statement cannot be true in any final sense, for it has been repeatedly shown that similar structures on the same individual may differ in ways attributable only to chance upsets themselves scarcely referable to differences in the genotype.

Now, evidence can be obtained about materials of genetical importance from three sources: by their direct observation, microscopically, chemically, and so on; by their behaviour in hereditary transmission; and by their action in producing their effects. Each kind of evidence has its own value and its limitations. Our task is not to set one against the other, but to combine them towards a fuller understanding of organization and action. It is, in a sense, the familiar and often complicated biological problem of elucidating and relating structure and function, appearing in a new setting. This emerges clearly from Goldschmidt's section on the nature of the genetic material where he analyses the concept of the gene—a term which he does not like and wishes to abandon. He was, in fact, the first to point out that the classical notion of the gene was too simple, and his latest discussion will be read with interest. He also discusses whether the deoxyribonucleic acid or the protein fraction of the chromosomes is the true genetic material, and finally favours the protein. His reasons for doing so are not clear, and indeed one wonders whether basically it is not simply because, as emerges much later in the book, he assumes that the genic material must act by producing replicas of itself, the agents of gene action being in fact proteins. This assumption itself is challengable, and indeed the very question he starts with is not obviously the right one. Both fractions would appear to be essential, so that one is led rather to ask what each does and how they complement one another in the joint function of reproduction and action.

Moving to the less-understood cytoplasm, the water becomes even deeper. Goldschmidt clearly has an intense dislike of the notion of the plasmagene—the "wobbly concept" as he calls it—and he is anxious to do away with it. His attempts will certainly not carry universal conviction. He rules out kappa particles, even as a model, on the grounds that kappa is a virus—deadly not to those carrying it but to those which do not—without ever discussing the criteria which distinguish virus and plasmagene, or analysing the deeper significance of these criteria. Plastids are likened to organisms and their evidence faded out; and the existence of information about cytoplasmic segregation in plants is mentioned, only to be dismissed on the grounds that, thinking of cytoplasmic differentiation and its obvious difference from genetic segregation, the zoologist will be "skeptical". The notion of the plasmagene may well have been abused; but it was introduced to meet a need, and it is not to be so lightly rubbed out. The inference of "self-propelling processes" and "steady states" on physiological grounds is no alternative to the postulation of self-producing particles in the cytoplasm from the evidence of transmission. One does not prove the other, but it equally does not replace it. Indeed, we are led to ask what basis the controlled self-impelling process has. Is it structural? Is it, in fact, some kind of plasmagene?

The cytoplasm has a structure and organization different from that of the nucleus. It does a different job. It appears more heterogeneous, and its parts may well have come together in a different way. We must expect these parts to be differently related one to another and to the nucleus. In short, they pose the problem of structure and function in a new and perhaps even more difficult way. We shall need all the evidence we can gain, whatever its source, and we shall need to clarify our concepts if we are to arrive at the answer. The history of the gene concept has surely shown us that the physiological does not replace the mechanical and that deeper understanding comes when we try, not to oppose, but to relate particle and process, structure and action, form and function.

One could go on through the full five hundred pages of the book objecting and arguing almost endlessly, and by so doing attesting, I believe, to Prof. Goldschmidt's success in at least one of his chief aims. "Theoretical Genetics" is avowedly for the specialist. It presents a point of view on controversial subjects, and a point of view to stir fruitful discussion rather than to secure facile agreement. It collects together an imposing amount of fact and opinion, though unfortunately not every author's views are correctly reported or their references correctly cited. It might have benefited by condensation, for there are lengthy digressions; and in any event the treatment is so exhaustive as at times to be exhausting. Cross-references, too, would have helped where evidence is touched on before being given in detail, and where a subject is taken up again on later occasions. It remains, however, a book which should be widely read among geneticists. Its arguments and conclusions will arouse disagreement, often deep disagreement; but in disagreeing we can scarcely fail to be challenged into critical examination of much that we too frequently take for granted.

Kenneth Mather

THE JEWS IN ANCIENT AND MODERN TIMES

This is Israel

Palestine—Yesterday, Today and Tomorrow. By Dr. Theodore Huebener and Dr. Carl Hermann Voss. Pp. x+166+8 plates. (New York: Philosophical Library, 1956.) 3.75 dollars.

THE first half of this little volume is devoted to a historical sketch. "Every effort has been made to treat the various religious and political issues fairly and objectively", states the wrapper, and the reader will endorse the claim. Remarkably succinct and lucid is the survey covering the Biblical period (with due use of modern scholarship), subjugation by Rome, the ministry of Jesus and rise of Christianity, the rise of Islam and the comparatively peaceful rule of successive Islam empires, the Crusades with massacres alike of Jews and Moslems, the successive Turkish invasions, the First World War, the Balfour Declaration (1917), the British Mandate, the war between Arabs and Jews, and the establishment of the State of Israel in 1948. This portion of the work would be usefully supplemented by more maps.

The remainder of the volume deals not with the political but with the cultural record. The authors touch on the preparation of the two Talmuds, building on Old Testament commentary a rule of life. Two dissenting Jewish bodies are mentioned: the Samaritans (a tiny group now fallen under Arab rule), and the Karaites, a scattered Jewish brotherhood who endeavour to follow literally the Old Testament rather than Talmudic and subsequent commentators. The linking is noted in Jewish consciousness throughout the centuries of the land of Israel with the sense of an Israelite religious mission. The authors mention also the friendly understanding reached in 1918 between the Jewish leader Weizmann and King Hussein of the Hedjaz and confirmed the following year by his son and heir, the Emir Feisul—an understanding not encouraged by British authority, who unfortunately deprecated also the beginnings of Israeli–Transjordan co-operation prior to the British transformation of Transjordan into the State of Jordan.

The story of Zionist aspiration and achievement is told through accounts of a few of the great protagonists of the drama. Very interesting is the account of the movement "Back to the Land" initiated by Aaron David Gordon—"this refined, sensitive, vegetarian non-resistant" from Russia, whose settlement, started in 1909 with twelve young pioneers at Dagania near the Sea of Galilee, still persists, transformed to fertility. "Today", state the authors, "over one fifth of the people of Israel live on the land and till the soil". Theodore Herzl, of course, bulks large in the story of Israel, as does Eliezer ben Yehuda, who established and enlarged the modern Hebrew language, though unfortunately too early to emulate Kemal Atatürk by conforming the language to Western Latin script. The moving and inspiring story is told of the American Henrietta Szold, founder of the hospital organization throughout Israel and supporter of the educational work. Space has not been found for mention of Aude Wingate, the great British officer who brought comfort to many in Israel, nor of Martin Buber, the noble contemporary Israeli philosopher of individual responsibility. The great Hadassah hospital, the Hebrew University of Jerusalem, the scientific research Institute at

Rehovot and the constantly extending Techneion at Haifa are, of course, mentioned. The work of all continues and grows, though the splendid buildings and equipment of the two first-named are to-day held sterile and unused by the State of Jordan. The amazing transformation of the desert Negev is also described.

Undoubtedly those who so devotedly and cheerfully labour to create the new Israel are sustained by the sense that they are path-finders for future generations not only in Israel but even over the whole world. Recalling how almost each one has, personally or through others beloved, suffered from the mistakes of the world behind us, who will call their aspiration priggish or even unreasonable ?

DOROTHEA WALEY SINGER

CONTROL OF HUMAN CONDUCT

Social Control

By Dr. Joseph S. Roucek and Associates. Second edition. Pp. viii+603. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1956.) 50s. net.

THIS is yet another of the immense array of introductory texts produced in the United States which deal with various aspects of the study of sociology. It opens by restating the familiar theme of increases of crime and chaos in the post-war world which leads to the conclusion that, "if mankind is ever to be free from fear of aggression . . ., the wise control of human conduct is far more significant than any degree of mastery of the world of nature". This is quite unexceptionable, if somewhat trite. But, unfortunately, we may be misled too readily by the suggestion that the book attempts to deal with the intimidating problem as to how "wise control" is to be exercised. Social control is quickly redefined in the opening paragraphs as the "processes, planned or unplanned, by which individuals are taught, persuaded or compelled to conform to the usages or life-values of groups", which begs the whole question as to whether these usages, etc., can be continued further into the twentieth century without undue loss, or even peril. Furthermore, the most important issue latent in this formulation, as to the extent to which social control can be effectively planned and executed—even within this narrow context—is given only the briefest and most superficial treatment.

For the most part, the book provides a very general and at times somewhat dogmatic account of the social and psychological influences which shape our personalities and our societies in ways we tend to take for granted. The social 'conditioning' of personality, the leadership process, propaganda and similar topics are all passed in review without any general conclusion being reached. The final chapter on "Social Control and the Atom Bomb" is characterized by a deep pessimism: the last sentence in the book is that "the doom of mankind may already have been decreed". Whether this is intended as a judgment based on mature reflexion on the problems of social control, or whether it is a merely irresponsible or somewhat unconsidered remark, is not clear. But it can only be regretted that the brief and somewhat naïve section on economic and social planning could not have been greatly expanded, so as to deal with the basic problem of "wise control" which is posed but not discussed, let alone resolved.

It is recognized that some kinds of public planning and administration are successful, and have provided the foundations on which the modern urbanized way of life has been based. But it has proved exceedingly difficult to widen and strengthen these foundations, and the fact has not been recognized that the time has come when precise questions as to how and why must be put, with all the intellectual and moral courage that we can command.

T. S. SIMEY

MODERN ASTRONOMICAL OPTICS

Proceedings of a Symposium on Astronomical Optics and Related Subjects

Held in the University of Manchester, April 19th–22nd, 1955. Ed. by Prof. Zdenek Kopal. Pp. xv+428. (Amsterdam: North-Holland Publishing Co.; New York: Interscience Publishers, Inc., 1956.) 45 guilders; 90s.

THE contents of this impressive volume cover a very wide field of problems ranging from abstract considerations on information theory to questions of a very practical nature concerning dye filters, interferometers, etc. But they all have one common denominator: they refer to problems characteristic of modern astronomy which, extending its observations to invisible objects—that is, to very faint and distant stars and star-systems—has to develop new methods of registering and analysing the observable data. These again give rise to quite novel difficulties.

Modern electronic devices make it possible, for example, to measure with photomultipliers, attached to the 200-in. telescope at Palomar, the light intensity of a star of not much less than magnitude 24, which would correspond to observing Sirius as far away from us as one million parsecs; it should be possible to measure even fainter stars. However, how will the observer locate such a star in the photometer if this star is invisible—that is, it cannot even be located on a photographic plate ? Similarly, when formerly the observer wished to make a spectral investigation of a star, he produced an image of this star on the slit of a spectrograph, keeping during the exposure the star image steady on the slit. For faint objects this is no longer possible. So different devices have to be developed to enable monochromatic analysis of very faint invisible light sources. The last chapter, on filter photography of thin films, is thus devoted to problems of this kind.

Since a great refinement is a common necessary feature of all observations, all disturbing effects, like the scintillation of star images, have to be carefully analysed to eliminate their influence; Chapter 5 deals with resolution problems and scintillation. It becomes thus also clear why the information theory plays an important part. The actually observed effects frequently appear to be scarcely related to what the observers actually wish to find out; thus a minute analysis of the content of information in the observed data is needed.

This book is a rich source of information for every modern astronomer. An astronomer brought up in the tradition of spherical astronomy and celestial mechanics may feel a bit bewildered, like a connoisseur of classical music or painting listening to music by Hindemith or looking at pictures by Braque.

E. FINLAY-FREUNDLICH

Flow of Gases Through Porous Media

By Dr. P. C. Carman. Pp. ix+182. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1956.) 30*s*.

IT is some twenty years since Dr. P. C. Carman suggested the permeability method for the measurement of the surface area of fine particles such as cement. During these years the range of interest in the flow of fluids through porous media has increased considerably, and in this book he has presented a concise account of the subject, including the recent work on gas diffusion and separation.

The primary aim of the book is to present a quantitative account of the flow process when a gas enters or passes through porous media. The theme of the book is a discussion of the Kozeny–Carman equation for the flow in such systems, and one of the great merits of the text is that the writer has explained in detail the limitations of this approach and the consequent reasons for its failure in some instances.

Chapter 1 contains a formal presentation of the Carman equation as developed for unconsolidated media, and in Chapter 4 the application of this equation for measurement of particle surface is given. Of greater interest is the discussion in Chapter 2 of the influence of abnormal pore texture, the distribution of pore size and the problem of flow through consolidated media.

Chapter 3 covers slip flow and Knudsen flow and a short account of diffusion in porous media. Chapters 5 and 6 contain an account of more recent work on the flow of sorbable gases, leading to a discussion on surface diffusion and gas separation processes. Finally, Chapter 7 covers the transition zone to turbulent flow and an introduction to the conditions of fluidization.

This is a scholarly text written by an acknowledged authority in this field, and it will be welcomed by all whose activities so much as touch on this subject. The book as written has rather a terse style, and a general introduction, particularly to Chapter 1, would have been of value to the more general reader.

Reduction with Complex Metal Hydrides

By Norman G. Gaylord. Pp. xvi+1046. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 15 dollars.

THIS book, which started in 1951 as a review article on reductions with lithium aluminium hydride, is a comprehensive survey of the preparation, properties and uses of all the complex metal hydrides known up to the end of 1953. The reactions of these hydrides with inorganic as well as organic compounds are described. Then there is a useful general discussion of reduction of organic compounds with complex metal hydrides: stereochemical features and analogies with Grignard reactions are reviewed. Each functional group has a chapter to itself, with full references and tables giving substance reduced, product and yield. In addition, the more interesting cases are described in fair detail with supporting formulæ and reaction schemes.

A very considerable number of the compounds mentioned are from the chemistry of natural products. The collecting together of so many examples will be of particular value to those investigating steroids. The information is set out in a very acceptable form, easy to follow. There are very few mistakes, either chemical or typographical. It is a pity that throughout the book aluminium is spelt aluminum.

The book of this size and scope, which could so easily have been little more than a catalogue, is interesting and informative. It gives a balanced view of this extraordinarily fertile field and will doubtless stimulate further research in both inorganic and organic chemistry. E. E. TURNER

Theory of Combustion Instability in Liquid Propellant Rocket Motors

By Luigi Crocco and Sin-i Cheng. (Agardograph, No. 8.) Pp. viii+200. (London: Butterworths Scientific Publications; New York: Interscience Publishers, Inc., 1956. Published for and on behalf of the Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization.) 37*s*. 6*d*.; 5.25 dollars.

A LIQUID-PROPELLANT rocket motor is a complicated system in which fuel and oxidizer are pumped through a perforated injector plate, combined in a combustion chamber and accelerated to supersonic exit-speeds in a Laval nozzle. This book is a compendium of theoretical considerations (related only perfunctorily to experiment) on the problem of understanding and learning to avoid such instabilities of the system as lead to oscillations of an organized character in the pressure and temperature in the combustion chamber; these can be responsible for mechanical or thermal failure of components. 'Chugging', or low-frequency instability, is ascribed to an interaction between the time-lag for change in injection-rate to produce changes in combustion-rate, the time-lag for these changes to evacuate the chamber to a different pressure, and the time-lag for this to affect the injection-rate through the equations of the pumping system. The equations are treated, in addition, for the case of a servo-mechanical control, which feeds back signals from the combustion chamber into the fuel flow-line, and for the case when the combustion time-lag itself varies with chamber pressure, which can lead to additional instability.

'Screaming', or high-frequency instability, is ascribed to the interaction of factors such as these with the normal modes of oscillation of the gas in the combustion chamber. Only 'longitudinal' modes (with motion along the axis) are here treated, although the authors admit that transverse and rotary 'sloshing' modes should also be considered important, as more recent work has, in fact, emphasized. M. J. LIGHTHILL

Atomic Physics

An Atomic Description of Physical Phenomena. By Prof. Gaylord P. Harnwell and Prof. William E. Stephens. (International Series in Pure and Applied Physics.) Pp. x+401. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 60*s*.

THIS book exhibits the difference between the methods of teaching in American and British universities. It is based on a course of lectures given by the authors to first-year postgraduate students at the University of Pennsylvania. The standard is suitable for British undergraduates in their final year; but the book would be expensive for students here at 60*s*. The nearest equivalent published in Britain is Max Born's "Atomic Physics".

D. F. JOHNSTON

THE CALDER REACTORS: RESEARCH AND DEVELOPMENT PROBLEMS

By L. ROTHERHAM

Director of Research and Development, U.K. Atomic Energy Authority (Industrial Group)

THE design of the reactors at the Calder Hall Atomic Power Station, opened by H.M. The Queen on October 17, sprang directly from a proposal made at the Atomic Energy Research Establishment in 1953 for a small power reactor called PIPPA to supply the electricity needs of the Establishment. This reactor was never constructed; but many of its main features have been retained in the Calder Hall reactors designed and built by the Industrial Group. No fuel other than natural uranium being available, a thermal neutron reactor with graphite or heavy-water moderation was essential. Heavy water was very expensive and not readily available in the United Kingdom. Its use would have required the core to be carried inside an exceedingly massive pressure shell in order that the necessary working temperature could be reached, and there were fears, which later experience has shown to be well founded, that there might be difficult problems in preparing fuel elements sufficiently resistant to corrosion by water at high temperature. The use of natural water-cooling for a graphite-moderated reactor is not physically impossible, but the same corrosion problems exist and it is doubtful if coolant tubes strong enough to stand the pressure can be made which will not absorb neutrons so avidly that a natural uranium pile becomes impracticable. The choice, therefore, fell on a gas-cooled graphite-moderated design. Many gases were considered from the aspects of coolant efficiency, neutron absorption, chemical stability and inertness at the working temperature and ease and cheapness of acquisition. Carbon dioxide was chosen, as it combines to a remarkable degree the desired qualities. Its nearest rival is helium, which can only be obtained from dollar sources and incurs high transport costs.

The choice of a graphite-moderated reactor cooled with carbon dioxide was supported by the belief that such a reactor could be built with a simple development programme in which all important problems could be foreseen at the start, and attacked simultaneously. Many types of reactor which have great potential advantages can only be constructed after a two-stage experimental programme has been carried through. For example, the nuclear-hydraulic mechanism which determines the manner and rate of boiling in a boiling-water reactor cannot safely be elucidated by theoretical studies alone, and the design of such a reactor for economic power must be preceded by the building and operation of an experimental reactor. This would delay the main programme by three to five years. For Calder Hall much useful information was available already from experience with BEPO and the Windscale piles, relating particularly to uranium fabrication and the manufacture and behaviour under irradiation of graphite. Unlike the water-cooled piles, the pressure of operation was determined by the economics of the circulating blowers and not by temperature, and a pressure of 7 atmospheres was chosen which led to a design for a pressure vessel only just outside previous experience. There was a further feature of great importance in the design. The use of natural uranium and the relative absence of neutron-absorbing material from the core allowed a good 'neutron economy'—that is, led to the maximum number of spare neutrons being captured in uranium-238 rather than in structural material or coolant. As a result, the 'conversion ratio' (number of plutonium atoms produced per uranium-235 atom fissioned or converted to uranium-236) is very satisfactory. Higher values can be obtained with cold heavy-water moderated piles of large size because of the very low capture cross-section of heavy water; but they are less likely to be realized with heavy-water power piles because of the presence of more extraneous material in the core and increased neutron leakage. As the Calder Hall reactors produce plutonium with by-product power, this high conversion ratio was desired; but it is just as valuable for a pure power pile because it allows better utilization of the fuel in each irradiation cycle.

The development programme comprised numerous individual jobs carried out at the Atomic Energy Research Establishment and in the laboratories of the Research and Development Branch of the Industrial Group. Some were started at Harwell before the design had been accepted for construction by Risley; but Harwell and the Industrial Group worked side by side thereafter. Only a selection from the experimental and theoretical work is described here.

Even if neutron cross-sections at all relevant neutron energies for all materials in the core were known, it would not be possible to calculate sufficiently accurately the reactivity of the fully loaded core. 'Exponential experiments' were therefore carried out at Harwell, in which the distribution of neutron flux was measured in sub-critical piles supplied with neutrons from an external source. These piles had lattice structures similar to that proposed for the main one, and from these measurements it is possible to deduce the reproduction constant of the infinite lattice, and the migration areas which determine the rate of escape of neutrons from a finite core. These quantities are needed to allow the effective reproduction constant of the actual reactor to be calculated. In principle, this type of experiment should give all the information needed. In practice, it is usually not possible to represent the actual reactor lattice arrangement exactly, because it is not known in time, nor can the effects of high temperature easily be simulated. Considerable theoretical ingenuity has to be employed in making use of these measurements. The original Harwell core design was chosen on the basis of existing knowledge to combine large power output and small core diameter while employing natural uranium. A re-evaluation was made in the Research and Development Branch at Risley, starting from a given core size fixed by the engineers, and aiming at optimum plutonium production without necessarily insisting on the use of natural uranium (by that time enriched uranium had become available from the Capenhurst Diffusion Plant). This led to changes which appear slight, such as an increase in the uranium rod diameter from 1 to 1·15 in., but which have quite significant effects on conversion ratio and other properties. When the structure was settled in detail, the expected reactivity was re-calculated, making the fullest allowance possible for the existence of zones of different properties within the core. These exist because of the different fuel channel sizes and varied expansion gaps between graphite bricks that are provided in different parts of the reactor. An ideal theoretical treatment of this problem, in which the neutron flux distribution in each zone is properly 'matched' to that in its neighbours by suitable boundary conditions, is not possible at present. We hope that by the use of automatic computers particular cases will be solved in future. For the present, judicious averaging and adjustments have given results in tolerable agreement with measurements, and by sound judgment and some luck the pile has turned out to be capable of operating on natural uranium. There are other theoretical problems which have to be solved in designing a reactor of this sort. The effectiveness of control rods, and the flux of radiation outside the core vessel must be calculated. The latter is needed in designing the shield and instrumentation.

Apart from these studies on 'neutron engineering', a considerable amount of development work to improve the heat transfer of the fuel was carried out both at the Atomic Energy Research Establishment and in the Industrial Group laboratories. Heat transfer generally imposes a limit on the maximum operating power of a gas-cooled reactor, in that it is impossible to remove more than a certain amount of heat from fuel elements at a given temperature without the expenditure of excessive power in circulating the coolant through the reactor. It is always possible to remove this limitation by increasing the coolant pressure, although structural considerations then impose a limit. Anything which can be done to increase the heat-transfer properties of the fuel elements themselves is therefore greatly to be desired.

The first line of development, used in the Windscale reactors, was to increase the heat-transfer surface by the addition of longitudinal fins to the fuel container. It was possible, by this means, to achieve ratings (MW./tonne) some five times greater than those which would have been possible with plain cylindrical fuel elements. Further development of this type of extended surface proved difficult because of poor mixing of the gas between the fins with that towards the outer diameter of the channel. This is a difficulty inherent in the gas-cooled natural uranium reactor, since the channels must be of large diameter (that is, about 4 in.) to accommodate the flow of coolant, and the fuel must be in the form of a cylindrical rod, for reasons of neutron economy.

Experimental work at Harwell led to the development of turbulence promoters, and a significant improvement was obtained by the use of these in the Windscale reactors. More important, however, this work led to the development of the transverse finned Calder fuel element. This type of fuel element achieved a given heat transfer-rate with a smaller mass flow and a higher outlet temperature than the longitudinally finned type, and the power required to pump the coolant is also rather less; it is therefore well suited for use in a power reactor where a high outlet temperature of coolant is desirable. Experiments have shown that there is a well-defined circulation in the form of two vortices 'geared together' in the space between the fins and maintained by the flow at the fin tips. It is this systematic circulation rather than the production of random turbulence which accounts for the good heat-transfer properties of the transverse finned element.

The instrumentation of the reactor presented a number of novel problems. For example, it is essential in a high-power reactor to be able to detect fuel elements with damaged sheaths. This is done by monitoring samples of the coolant gas for fission-product activity. Each of about two thousand fuel channels has a sampling pipe which runs through the pressure vessel to a selector valve and thence to a detector, the samples being returned to the circuit by a special blower after monitoring. The samples are filtered to remove solid matter and are then exposed in a precipitation chamber where solid decay products from gaseous fission-product elements that may be present are deposited on a wire. The wire is drawn into another chamber, where it is observed by scintillation particle detectors which report its state of contamination. The counter assembly, which has to work in high-pressure carbon dioxide, was developed in the laboratory at Windscale.

The principal metallurgical problems of the Calder reactors were concerned with the fuel elements and the pressure vessel. These are always likely to be key problems in reactors of this type, since there will always be technical and economic advantages in designing as close as possible to the limit on these points. At the same time, an extremely high degree of reliability is required in both fields. It will be obvious that a major failure of the pressure vessel could be a very serious matter, especially if it occurred in a brittle fashion. Although failure of a single fuel element would not be disastrous, only an extremely low incidence of failure can be tolerated if the reactor is to operate consistently; furthermore, this degree of reliability will be required for increasing lives in the future.

Pressure Vessels

The general problems of building steel pressure vessels for reactors of the Calder type are extremely interesting scientifically. The size of the Calder vessels, the thickness of steel plate involved and the continuity of the welded construction are all features which increase the tendency of the structure to fail in a brittle manner. In addition to the problem of brittle fracture, however, the temperature-range in which creep becomes important may be entered, and this is a combination of circumstances which is quite unusual. In addition to these factors, site fabrication, the oxidation resistance of the steel, the stress relief and inspection of the completed vessel and the effects of irradiation on the steel must be taken into account.

Certain general features of the brittle fracture phenomenon have now been elucidated, and it is recognized that steels vary in their tendency to propagate or to arrest cracks. Methods of reducing the tendency to brittle failure by means of composition and/or heat treatments are available, although the difficulty of doing so increases with thickness of plate. Unfortunately, however, there is no way of applying the available data quantitatively in a design, so that design engineers must exercise their judgment in a qualitative fashion, based on previous experience. At the same time, metallurgical features which provide a higher measure of notch ductility may reduce creep resistance; the grain size is particularly important, a fine grain being desirable for a low temperature (for the transition from brittle to ductile fracture) but disadvantageous from the creep point of view.

Up to about 375° C., creep effects can largely be neglected in the design of steel structures. However, if the pressure vessel is exposed to the hottest gases as well as irradiation, which causes internal heating, the creep range may readily be entered. In this case, the provision of adequate long-term creep data becomes a very difficult problem, since very long lives are involved and allowable strains are very small: 0·1 per cent strain in twenty years is typical. In addition, relatively little is known of the ductility that may be expected under these conditions and for such long times. In the case of the Calder reactors, only modest cooling was required to avoid creep problems, and this solution was accepted. It was then possible to select a steel with excellent notch ductility so that the maximum factor of safety from brittle fracture was provided. In future designs, however, which may be required to operate with higher gas temperatures but where at the same time cooling would be more unattractive on economic grounds, it may be necessary to deal with both creep and notch ductility simultaneously. There is scope for the development of special steels to withstand this combination of conditions, and this is being pursued with encouraging results.

The effect of irradiation on the properties of steels is not fully understood, especially when the irradiation is carried out below about 300° C. Samples have been loaded into the Calder piles both to provide a continuous check on the condition of the steel in these reactors and to provide more quantitative data for future designs.

Oxidation studies in carbon dioxide carried out on steel samples indicated that no important problem need arise in reactors of this type. Site fabrication and inspection problems, however, required considerable thought, and this is likely to be the case in subsequent reactors also.

Fuel Elements

For the fuel elements, a very considerable research and development programme was required. This programme may be divided arbitrarily into the following three phases, although it will be realized that there was actually considerable overlap in time: (*a*) feasibility studies; (*b*) specification of fuel element and of manufacturing processes; (*c*) studies of probable behaviour in the reactor.

During the feasibility period, it was necessary to show that the general style of fuel element proposed was broadly satisfactory, both from the point of view of manufacture and pile behaviour; in particular, the feasibility of the general size and shape of the element and the choice of a magnesium alloy for the finned sheath had to be demonstrated. Following the decision to proceed with the reactor, one of the most urgent problems was to develop methods for the production of the cans, which involved the bulk manufacture of a completely new magnesium alloy to more rigorous standards of cleanliness than for any previous requirement and the final fixing of the alloy after many experiments on oxidation and corrosion, weldability and deformation behaviour. For the uranium bar, processes had to be developed for casting longer bars than previously used and heat-treating them to a newly defined metallurgical condition. The fuel element manufacturing processes were, of course, completely new, and included many stages; those of greatest importance are probably welding of the end seals, decontamination of the external surface from traces of uranium and the final inspection processes needed to guarantee the high standards of reliability required.

The last category of work, however, that of studying probable behaviour in the reactor, is of greatest interest scientifically and, of course, is devoted not only to proving the first fuel elements but also to the development of better fuel elements, both for the Calder and more advanced reactors. The aim has been to try to predict the various changes that may occur in service which may influence the behaviour or life of fuel elements and to determine, with progressive accuracy, their magnitude. This work permits an estimate of the life of the first fuel elements to be made and, by indicating the probable limiting features, is expected to lead to rapid improvements in the elements for these reactors and valuable information for the design of future reactors.

Unfortunately for the analytical studies, very little information was available on irradiation damage at the outset and, up to the present time, experiments on prototype fuel elements have necessarily been limited in such respects as size, burn-up and thermal and neutron gradients; this is inevitable in the current phase of reactor development. However, theories existed concerning the mechanisms of irradiation damage in uranium, both as regards overall dimensional changes and local surface effects ('wrinkling'). These theories predicted that improved stability would be obtained from a fine and random grain structure. Evidence that this was likely to be true under Calder conditions was obtained, and suitable heat-treatment processes were defined just as the cartridge production line was being constructed. It is believed that this particular problem has been solved, and that the Calder cartridges will be adequately stable to the burn-up required. New phenomena are, of course, expected to become increasingly important as future reactors of the Calder type require higher burn-ups and temperatures; ideas on these matters are developing.

For various reasons it was desirable in the Calder reactors to make the fuel elements as long as possible and to stack them vertically, one above the other. It was appreciated that this would probably lead to progressive bowing of the elements, especially in view of the high density of uranium, and this has led to an extensive creep programme. Relatively little was known of the creep behaviour of uranium, and the present work has been complicated by a number of factors, including the complex longitudinal and radial thermal gradients in the uranium column, which had to be based on calculation rather than experiment. The calculation of bowing from basic creep data, therefore, proved difficult, particularly as the strain-rates of interest were very much lower even than those determined in high-sensitivity creep tests. Furthermore, the creep properties of different uranium specimens varied greatly, and were affected to an unusual extent, compared with other metals, by trace impurities and grain size. Although the uranium as produced at Springfields is an exceptionally pure metal, it had not previously been necessary to relate impurities to mechanical properties, and this new requirement coincided both with development work to produce purer uranium and with the heat-treatment studies mentioned above. In addition to the tensile creep work, it was desirable to carry out rig tests, both in and out of pile. Finally, A. H. Cottrell, of Harwell, has considered the possible effects of irradiation on creep behaviour; this work, which is to be published shortly, indicated a possibly important effect which had to be taken into account. Despite these difficulties, it has been possible to give a reasonable forecast of bowing behaviour in the Calder reactors. Although this is unlikely to be an embarrassment in these reactors, the information obtained will probably lead designers away from the use of uranium as a load-carrying member in future power reactors.

Although it was necessary to study the magnesium canning alloy from many points of view, the work on mechanical properties is probably of greatest importance. In the pile, the magnesium must have adequate strength, both as a link in the load-carrying structure and also in order to retain the correct shape of the heat transfer surfaces. At the same time, there must be sufficient ductility, in the presence of welds and other stress-raising features, to withstand, without the formation of the slightest crack, the inevitable strains resulting from the temperature and irradiation effects on the cartridge, some of which have been mentioned above. This combination of properties is required under irradiation over the whole range of temperature encountered in the pile.

Magnesium, a hexagonal metal, has relatively low ductility at room temperature, whereas at the higher temperatures in the Calder reactors its strength is falling off rather rapidly. However, in view of the advantages from using magnesium, careful work was undertaken to assess these factors and to modify the properties of the material, as necessary. Many creep tests were carried out, including some under predetermined strain schedules rather than with a fixed load, since this gives more information on the unusual strain conditions in the reactor. In these tests particular attention has been given to ductility, both general and local, and to the phenomena related to the onset of crack formation. Two interesting features have been noted. One is that under appropriate conditions, small voids are formed; these have a characteristic size and concentration determined both by the material and the strain conditions, which may include irradiation. The other feature is that grain size, frequently a disadvantage with magnesium alloys, has a large effect on deformation mechanisms. The grain size of interest, of course, is that which is stable at reactor temperatures, and this increases the difficulty of control. For the first cartridges for Calder, major changes in composition were not possible; but modest adjustments to the composition of the alloy were found to be useful as a result of critical strain/grain growth experiments. Although for the future a complete theoretical survey of magnesium alloys has been carried out and several systems selected for experimental work, there is a growing feeling that the present material has a combination of properties fairly well suited to the wide and somewhat conflicting requirements of reactors of this type.

The work of the development teams, of course, was not ended with the completion of the reactor. During the start-up the physicists of the team worked on control problems and made the nuclear measurements which have confirmed the work of the past years.

The effect of varying the operating parameters was studied, the effect of fission-product poisoning determined, the control rods calibrated and their optimum disposition investigated; in general, a very clear picture of the characteristics of the reactor was obtained.

Work will continue in future years, and facilities are provided in the reactor to permit the study of the effect of irradiation under the appropriate conditions on fuel, graphite and pressure-vessel steel. Teams of the Research and Development Branch of the Industrial Group, together with their colleagues in the four industrial nuclear power companies, are working on the advancement of the technology of gas-cooled reactors. Calder presents the first step in the carefully planned development of gas-cooled nuclear power stations. The experience on the first reactor, and the improvements we now know can be made, lead us to believe that the decisions taken several years ago were the right ones.

GEOLOGY OF KILIMANJARO*

By DR. C. DOWNIE, DR. D. W. HUMPHRIES, W. H. WILCOCKSON and P. WILKINSON

KILIMANJARO, situated on the border between Kenya and Tanganyika, presents special claims for geological attention. In the first place, it is one of the largest volcanic mountains in the world and the highest mountain in Africa, the summit reaching 19,340 ft. above sea-level. The mountain mass is 50 miles long and 30 miles wide and contains more than 1,000 cubic miles of volcanic rock. Though only 200 miles south of the equator, because of its great height it has a permanent ice cap and exerts important local meteorological effects which are a major factor in the provision of water for the surrounding important agricultural region. In the second place, Kilimanjaro belongs to the East African Rift Valley petrographic province, the rocks of which belong to the alkaline suite which plays so prominent a part in petrogenetic theory. The association of rocks is so characteristic that apart from certain localities in East Africa, of which Mount Kenya is one, it can only be closely matched, petrographically and chemically, in the widely separated areas of the Oslo District in Norway and the Ross Archipelago in Antarctica. Detailed analysis of the geological and tectonic features of these areas, already known to be similar in certain respects, may be expected to throw new light on the origin of the rocks and on theories of petrogenesis generally.

Such considerations, together with the question as to whether Kibo, the highest summit, is likely to erupt again, and doubt concerning the effects on

---

water-supply of the shrinking glaciers, prompted the Geological Survey of Tanganyika to invite four members of the staff of the Geological Department of the University of Sheffield to join with three of its own geologists in making a reconnaissance survey of the mountain in 1953. The results so far obtained[1] are briefly set out here.

Composition and Structure of Kilimanjaro

The volcanic mountain rises more than 15,000 ft. from a platform of basement rocks varying from 2,500 to 4,000 ft. above sea level. Since the geological age of the mountain is not great, its innermost portions have not yet been laid bare by erosion, so that, generally, knowledge of its superficial rocks only can be obtained; the one really deep section to be seen is at the east end where two great gorges, the Mawenzi Barrancos, have been cut and expose between 4,000 and 5,000 ft. of volcanic rock. Nevertheless, it is clear that, from an early stage, activity was concentrated at three main centres corresponding to the main topographical heights, Shira, Kibo and Mawenzi, and the early activity at these centres may well have been contemporaneous. So far as can be seen, the early lavas were trachybasalts, which later gave place to phonolitic rocks.

The most degraded of the three peaks is Shira, a trachybasaltic cone which attained a height of 18,000 ft., but underwent cauldron subsidence. The resulting caldera is now represented only by the south and west walls, which form a long ridge rising to little more than 13,000 ft. After the cauldron subsidence was complete, an inner cone, the Platzkegel, was built and the volcano was invaded by a suite of radial dykes. At one point on the ring-fracture a parasitic vent erupted phonolitic lavas. After activity at this centre ceased, the eastern and northern walls were eroded and the caldera floor was flooded by lavas from Kibo.

Mawenzi, the eastern peak, has also suffered much from erosion and is now a craggy mountain, nearly 17,000 ft. high, with little resemblance to a volcano. It also is composed almost entirely of trachybasaltic rocks; but locally, in the later stages, flows of olivine basalt occurred. The rocks of the upper parts of the mountain were described by the German workers as "Brockentuffen", but, though true agglomerates do occur, a large proportion of the apparent pyroclastic rocks have proved to be flow breccias which are unusually thick in comparison with the amount of solid lava. This indicates that these lavas must have moved with a flow mechanism which may be related to the formation of 'aa' as reported from the volcanoes of Hawaii. Mawenzi was essentially a volcanic cone of which the structure has been complicated by multiple vents. The plug of dioritic rock filling the main vent is exposed in the East Barranco at 14,000 ft. The last phase of the vulcanicity of Mawenzi was the intrusion of an extensive suite of trachybasaltic and basaltic dykes, more than a thousand in number, most of which are grouped in a parallel swarm, though some of them have a radial arrangement.

At the end of the period of effusion of trachybasaltic lavas Kibo formed a cone probably about 18,000 ft. high; but activity continued here after the eruptions had ceased at the other centres. These later eruptions began with the outpouring of rhomb-porphyries followed by other phonolitic lavas by which the present complex puy-shaped cone was

built up (Table 1). The mountain gives evidence of three distinct episodes of cauldron subsidence. The first affected the main rhomb-porphyry cone, but is much obscured by later flows. The second formed the present topographic caldera, and the third the crater of the Inner Cone. In the Inner Crater, solfataric activity with extensive deposition of sulphur is still continuing[2].

A late stage in the volcanic history was the development of a large number of parasitic cones, some forty of which have been mapped above the forest belt alone. They are distributed along west-north-west to east-south-east and north–south lines across the mountain and are composed of pyroclastic rocks and basic and ultrabasic lavas.

Petrogenesis

The trachybasalts are striking rocks containing abundant thin tabular phenocrysts of plagioclase in a matrix of plagioclase with some potash felspar, augite and iron ore. They are present in great volume and, so far as can be seen, make up the greater part of the mountain. On the other hand, the phonolitic lavas have a much smaller bulk and do not exceed 1 per cent of the total extrusives. The rhomb-porphyries, the most abundant of the phonolitic types, contain large phenocrysts of anorthoclase, usually with olivine in a fine-grained matrix generally of alkali felspar, augite and iron ore. They have much in common with similar rocks from Oslo, Mount Kenya and the Ross Archipelago. In the more alkaline lavas poured out late in the history of Kibo there is abundant nepheline, often as large phenocrysts. The basic and ultrabasic rocks, found principally interstratified with the trachybasalts of Shira and in the parasitic cones, are olivine basalts and ankaramites rich in augite and olivine. These lavas are of distinctly alkaline character, and, in some cases, develop abundant large nepheline phenocrysts and so may be called ankaratrites.

Consideration of the succession, petrographic characters and the chemical variations of this rock series indicates that we are here dealing with a consanguineous suite, with a parental magma near to the trachybasalts. The ultrabasic rocks appear to have formed by the accumulation of early augite and hornblende. The later phonolitic lavas show an enrichment of alkalis, suggesting a course of differentiation similar to the line of descent described from other alkaline volcanic provinces. The general trend of change in the Kilimanjaro rocks is fairly closely paralleled in the region in and around the Gregory Rift Valley, where trachybasalts are widespread among the earlier eruptions and are followed by more alkaline types.

Glacial History of Kilimanjaro and its Bearing on the Date of the Vulcanicity

During intervals in the effusion of lava it is clear that glaciers extended far down the mountain slopes. Boulder beds with striated pebbles occur at several localities associated with bedded sands and valley erosion in the pre-existing lavas. No evidence of glaciation appears to be present in the Shira and Mawenzi successions, and the last activity of these centres appears to have pre-dated the ice age. The younger lavas of Kibo, however, are separated from the trachybasalts by a period of erosion, and the succeeding activity, which is confined to this centre and the parasitic cones, was interrupted on several occasions by major glacial episodes. The glacial sediments deposited during these periods are found at definite horizons in the lava sequence on and around Kibo, and these are indicated in Table 1. Succeeding all activity, except for solfataric activity and perhaps the outpouring of the Inner Crater lavas, there was a further extension of the ice which deposited great moraines as low as 11,000 ft. on Mawenzi and Shira as well as Kibo. Nilsson[3] suggested that these belong to the Gamblian period, and it is therefore tempting to correlate the earlier extensions of glaciers with the three earlier Pluvial periods of East Africa, and the more recent moraines with the succeeding Makalian and Nakuran episodes. Thus the main activity of the mountain is pre-Pleistocene and, if Dixey[4] is correct in his interpretation of the Pangani River system, of Pliocene age. During the Pleistocene period only Kibo was intermittently active; but it is uncertain if any activity, except that of the solfatari, persisted into the post-Glacial period.

Present Glaciers of Kilimanjaro

The present glaciers of Kibo are but the ragged fringe of the ice cap which formerly covered the whole summit of the mountain, the centre having largely disintegrated and ablated. There is no ice in the Inner Crater or in the Ash Pit. Within the Caldera Wall there are isolated, stagnant ice masses which are decaying rapidly. The major glaciers occur on the southern and western flanks of Kibo, the Penck Glacier reaching to below 16,000 ft. These glaciers commence just below the crest of the Caldera Wall and are thus cut off from any potential-gathering ground (or 'névé-field') on the summit of the mountain. The glaciers of the northern slopes are more limited in extent, and although commencing within the outer crater wall are also without névé-fields. Thus the glaciers of Kilimanjaro are almost stagnant, and their recession is rapid. It seems likely, therefore, that within a few decades the ice will have entirely disappeared.

From such a reconnaissance survey our knowledge of the mountain must still be incomplete. It is hoped to fill in some of the gaps during a second expedition in 1957.

GLASS: RECENT RESEARCH AND DEVELOPMENTS

THE systematic study of glass and the subject of glass technology is a field with which the University of Sheffield is particularly associated, Sheffield being the only University in the United Kingdom which has a Department of Glass Technology, and, in fact, this was the first such Department in the world.

The existence of this Department and its growth is largely due to the work and vision of Prof. W. E. S. Turner, who first organized the Department in 1915 and became the first professor of glass technology in 1920. It was very fitting, therefore, that Prof. Turner should have been present to give an introductory talk to the meeting of Section B (Chemistry) of the British Association on September 4 at Sheffield which was devoted to glass. In his talk, Prof. Turner dealt with the history and development of the subject since 1910, the year in which the British Association last met in Sheffield. He referred to the parts which chemistry, physics and engineering have played, and continue to play, in the extension of understanding and practice in the industry, themes which were developed by the subsequent speakers.

Prof. R. W. Douglas, the present occupant of the chair of glass technology in the University of Sheffield, spoke on the nature of glass. After stressing the importance of the viscosity of glass and the manner in which it varies with temperature in glass manufacturing processes, he said that this relation of viscosity with temperature is of fundamental importance in any discussion of the chemistry and physics of glass. The high viscosity is associated with the nature of the forces between the atoms; the directed bonds between silicon and oxygen being particularly important.

Silica melts at 1,713° C.; but the liquid so formed flows with great difficulty because of these strong directed forces, and it is easy to cool the liquid through its freezing point without its solidifying. It is this mechanism which makes the formation of glass possible, and in this sense glasses are supercooled liquids.

On cooling further, a second stage of thermodynamic instability is reached. The distribution function of a liquid has a particular value for each temperature; but the difficulty of the atoms moving in respect to one another increases rapidly as the temperature falls, until the time taken for the distribution function to reach the value appropriate to the lower temperature becomes long compared with the time taken to make an experimental measurement. The properties of glass then appear to vary with time towards equilibrium values corresponding to the temperature of the experiment. This behaviour is observed when the temperature falls below that at which glass has a viscosity of about 10^{13} poises.

Eventually, after cooling roughly another hundred degrees, the rate of approach to equilibrium configuration becomes so slow that the distribution function is fixed. At room temperature glass is therefore a very special type of solid which has the macroscopic mechanical properties of a solid but in which the atoms are arranged with the disorder of those of a liquid and in which thermal motion of translation has ceased.

The function of other oxides, added to silica to produce glasses which have properties required for ease of fabrication, were mentioned briefly.

This theme was taken up by Mr. W. J. R. Merren, of Pilkington Brothers, Ltd., who dealt with new glasses. This title included many special kinds of glass which had been prepared to meet the demands of scientific development, the needs of research, and of new developments in various industries.

New optical glasses which have very high refractive indices were mentioned; these contain considerable amounts of the rare-earth element, lanthanum. Another development in optical glasses has been the production of glass of extremely high transparency. This involves the use of very pure materials and the melting of the glass batch in platinum vessels on a commercial scale.

Other glasses have been developed which absorb infra-red radiation, and are very useful, for example, in projectors to prevent overheating of the slides. Glasses are also required which transmit infra-red radiation. In preparing these glasses it is important to reduce, so far as possible, the very small amount of water which ordinary glasses can contain, for this small amount is enough to cause very marked absorption. It seems that for work beyond 5μ, glasses based on silica will not be useful; in this region selenium and sulphide glasses can be used, arsenic sulphide glass transmitting out to 15μ.

The developments in atomic energy have also made demands on the glass technologist. Radiation-absorbing glasses have been sought for one type of protective window, and a lead glass which contains as much as 80 per cent lead oxide has been made for this window. A window 3 ft. × 2 ft. × 2 ft. (the great thickness is necessary to get sufficient absorbing power) will weigh about 4,000 lb. A similar glass, when especially pure and transparent, has found application as a γ-ray detector by using the Čerenkov radiation.

Certain glasses have the property of changing under the action of harmful radiation, either developing a colour or an ability to fluoresce which they did not possess before, and so can be used to measure the 'dose' of radiation to which they have been exposed. Glasses such as these are quite different from the normal soda-lime-silica glass. Glasses for absorbing X-rays, for example, may contain large quantities of elements such as tantalum, boron, phosphorus and germanium, while the dosimeter glasses are potassium, barium, aluminium phosphates with as much as 7 per cent silver in them.

Dr. J. H. Partridge, of the General Electric Co., Ltd., continued Mr. Merren's theme, dealing with the demands which the lamp and electronic industry has made for new glasses. Here again, constituents which had not been thought of as useful in glassmaking thirty years ago are being used, or constituents such as soda and other alkaline oxides which were considered essential in earlier times are omitted. For example, the inner tube of the mercury lamp which is familiar in street lighting installations is made of a glass which contains no alkali. At 700° C. an evacuated tube of this glass about 30 mm. in diameter and 1 mm. wall thickness will become distorted only very slowly.

Another glass, used for making the sodium discharge lamp, is remarkable in that it contains no silica. This is in order that it shall withstand the attack of the sodium vapour. Other special glasses have had to be developed in order that suitable wires can be sealed through glass to secure and make contact with the electrodes in thermionic devices; such glasses must have a very high electric resistance. Dr. Partridge's paper was illustrated by an excellent colour film of glass-making operations; this film emphasized the changes in normal procedure entailed in making articles from some of these special glasses.

A paper different from the others, in that it dealt with a new industry which has grown out of the glass industry itself, was presented by Dr. A. De Dani, of Fibre Glass, Ltd. Glass fibres may be drawn as single continuous fibres or by the glass wool process. This process consists in subjecting a stream of glass issuing from a platinum orifice to an intense blast of superheated steam. The stream of glass is thus shattered, resulting in a multitude of very fine fibres of glass. It was thought at one time that the steam shattered the glass into droplets which were then drawn into fibres, but calculations showed that this explanation was not very probable. The process has therefore been investigated using high-speed ciné photography.

Some of the films taken in the experiments were shown to the meeting. The audience was thus able to see an example of industrial research in a new development of the glass industry; thereby completing the review of the many-sided aspects of glass technology—a subject in which physics and chemistry must be applied for a fundamental understanding of the material, in which physics, chemistry, engineering and mathematics are applied in the industrial development, and an industry which, although several thousand years old, is now, with few exceptions, such as high-quality table-ware and decorative pieces and the production in small quantities of special glasses, a fully mechanized industry.

SEVENTH INTERNATIONAL ASTRONAUTICAL CONGRESS

THE Seventh International Astronautical Congress was held in Rome this year during September 17–22, and was attended by more than four hundred delegates from many various countries and of equally varied interests. There is, of course, practically no scientific subject which is not involved in astronautics one way or another, and which does not stand to profit from its findings. The proceedings took place in the magnificent Congress Hall of the Espozisione Universale di Roma, and during the two and a half days of technical sessions more than forty papers were presented. An unusual feature—at least for a scientific meeting—was the use of a simultaneous translation service in Italian, French, German and English. Despite the valiant efforts of the Italian linguists providing this service, it would no doubt have been improved had the translators been natives of the country into whose language they translated, and had they had a knowledge of scientific terminology. These stern requirements would seem necessary to ensure the complete success of such a service.

With so many papers to be presented, only a quarter of an hour was allotted to each speaker, and there was practically no time for formal discussion. This made the task of digesting the contents of many of the lectures difficult, particularly as many of them were not available in printed form. Special interest was aroused by the contributions of the delegation from the United States, who, numbering among them the first professional 'astronautical engineers', introduced an atmosphere of reality unusual in conferences on this subject. With regard to the speculations concerning the relative progress of the American and Soviet attempts to set up an artificial Earth satellite, it is not inappropriate to remark that the only Soviet delegate, Prof. L. I. Sedov, of the U.S.S.R. Academy of Sciences, disclaimed any knowledge of his countrymen's progress in this venture and declined to make any statement on the subject.

The American artificial satellite, or to give it its code name, 'Project Vanguard', formed the subject of many papers. It is to be a three-stage rocket, appearing, however, to be composed of only two stages, because the last stage is carried inside the second. The initial stage is 44 ft. long and 45 in. in diameter, and is powered by a liquid oxygen rocket with kerosene as a fuel, and pressurized by helium; it is intended to carry the projectile to a height of 36 miles, and to achieve an all-burnt velocity of 5,500 ft./sec. The casing of the initial stage, after being jettisoned, is expected to land at a distance of 75 miles from the launching station. The second stage is 32 ft. long, and employs a bifuel rocket unit with nitric acid and hydrazine hydrate as propellants, and also pressurized by helium. It is expected to increase its speed to 13,400 ft./sec. at all-burnt, when its height would be 140 miles. Besides enclosing the final stage, it contains the control and guidance equipment, which is to be brought into action during a period of coasting flight after the operation of the second-stage rocket, to effect the critical final adjustments to the course of the projectile. The final stage of the rocket is then spin-stabilized, and launched from within the nose of the second. It consists of a solid-fuel rocket mounted on a magnesium alloy sphere, 20 in. in diameter, which is the Earth satellite itself. The final velocity would have to be about 26,000 ft./sec. and it is anticipated that the perigee of the satellite's orbit would be about three hundred miles from the surface of the Earth. When the casing of the solid rocket is at last jettisoned, about ten minutes will have elapsed since take-off, and the satellite will have travelled some fifteen hundred miles from the launching point.

The projectile is finless, and control on the first two stages is to be obtained by deflecting the rocket venturi on gimbals. A considerable degree of accuracy in both final speed and direction of motion is required if the orbit is to be successfully established. As an example, if there is no error in speed and if the perigee is not to be less than two hundred miles above the Earth, nor the apogee more distant than eight hundred miles, an angular error of about 3° in the direction of motion is all that can be tolerated. On the other hand, if there is no angular error, and the orbit is to be within the same limits, the velocity error must be no more than ± 450 ft./sec. No official commitment on expected accuracy is forthcoming, though it was suggested in discussion that as many as fifty satellites might have to be launched to give a reasonable likelihood that one might be placed in a satisfactory orbit. Precisely what would form a 'satisfactory' orbit is, in any event, difficult to define. The magnitude of the air density—and so of the drag—at such extreme altitudes is the chief factor governing the useful life-time of the vehicle, but is also one of the unknown properties which it is hoped that observation of the satellite may enable to be evaluated. Tentative estimates put the mean loss in apogee and perigee at (initially) about 250 ft. and 200 ft. per day, respectively. Because of the Earth's oblateness, the variation in the radius of the apogee and perigee is in fact oscillatory, with a period of forty days and an amplitude of about two miles.

It is hoped that observation of the track of the satellite vehicles may also supply data leading to determinations of the variation of gravitational acceleration, and of the shape of the Earth. In addition, it is hoped to be able to interlock the geodetic networks of the continents more closely than has been possible before. During the initial circuits in the orbit, the satellite can be located by the radio signals it sends out; but as the batteries have only a limited life, later observation will depend on visual and photographic records, when the satellite is visible before dawn or after sunset. In this 'Operation Moonwatch', the help of amateur astronomers all over the world is being enlisted, through the International Astronautical Federation. The track of the satellites takes them eastwards as far south as 45° latitude on the Greenwich meridian, and north to the same latitude at a longitude of 180° (so that they will not be visible in Britain). Some other data are to be telemetered from the satellites, though it seems that there is little room for the installation of many instruments. The weight of the satellite is only 21½ lb. (The complete take-off weight of the three stages is 22,600 lb., implying a mass ratio of more than a thousand.) The nature of the observations to be made was not announced, though the possibilities are without limit. High on the list of priorities is the counting of impacts by meteors. This and many other experimental techniques which might be involved are being practised already, and several of the papers presented at the Congress dealt with them.

One of the greatest of the potential hazards to man in space flight is the effect of heavy primary cosmic radiation. More than twenty-five stratosphere balloon flights conducted by the United States Air Force have carried biological specimens to altitudes above 30 km. in geomagnetic latitudes above 55°. Although no somatic health hazard has been observed over periods of about twenty-four hours—the longest period of exposure obtained—the repeated observation of streaks of grey hair on black mice, 200μ in width, has suggested that a so far unidentified mechanism causes wider radial spread of radiation effects (by some 20 times) than has been predicted before. In another paper, details were reported of personal experiences during half-minute periods in a zero-gravity condition. (These were experiments conducted in an aircraft.) The majority of the subjects tested reported as feeling "very comfortable".

Looking still further ahead, another paper discussed the time dilation effect of relativity theory, and its effect on humans travelling in a vehicle moving at speeds near that of light. The general conclusion seemed to be that man's life-time would be effectively increased to such an extent that he can survive outward journeys which in terms of light-years of distance far exceed his normal life-time.

T. NONWEILER

OBITUARIES

Prof. J. B. Leathes, F.R.S.

WITH the death, at Montreux on September 14 at the age of ninety-two, of Prof. John Beresford Leathes, physiology lost another of its dwindling links with the past century. Born on November 5, 1864, the son of a clergyman, and educated at Winchester and New College, Oxford, he also was intended for the Church; but a natural bent for science drew him to the study of medicine, and he qualified M.B. in 1893, and F.R.C.S. a year later, from Guy's Hospital, London.

A talent for chemistry, the teaching of which was a strong feature at Guy's, decided Leathes to follow the applications of chemical knowledge to the elucidation of physiological problems, in pursuit of which plan he went to work for two years with Drechsel at Berne, and then under Schmiedeberg in Strasbourg. On his return, like Sherrington before him, he was appointed to the lectureship in physiology at St. Thomas's Hospital, where he stayed for some ten years, during the last eight of which he also held a part-time appointment at the Lister Institute, which was one of the main foci of development for the rapidly evolving subject of biochemistry. He thus became one of that small and devoted band which included C. J. Martin, Harden and Young, Cathcart, Dakin and Raper, who did so much to forward the interests of that subject in its formative years. It was in that stimulating environment that his interest in metabolic problems was aroused, and where his book, "Problems in Animal Metabolism", was produced. His first published papers dealt with body fluids, proteolytic enzymes, protein metabolism, and the fat content of various muscles. Most of his subsequent work had to do with fat metabolism, and in much of this he had the collaboration of H. S. Raper; their joint monograph on "The Fats" (1910 and 1925) is still a standard work.

In 1909 he became professor of pathological chemistry at Toronto, where he was shortly joined by Raper. During these years he was elected to the fellowship of the Royal Society (1911). In 1915 he went as professor of physiology to Sheffield, in succession to J. S. Macdonald, who had moved to Liverpool, and he remained there until his retirement in 1933.

Leathes took a keen and practical interest in medical and dental education, and by reason of his work on the General Medical Council, and as dean for nine years of the Sheffield Medical School, he not only influenced his own University, but also played an important part in shaping the medical curriculum of his time. It is no more than fair to say that he, and the late Sir Arthur Hall, together were largely responsible for making the Sheffield Medical School the outstanding success it became. Their aim was to unify the medical curriculum; and they did this by weakening the barriers between the pre-clinical and clinical courses of study by extending physiology and biochemistry, with appropriate laboratories, into the ward teaching of clinical medicine—a development which has since been applied in other schools. The results of the experiment were encouraging, as also were those of an innovation which Leathes introduced into the B.Sc. course, and which consisted in making the candidates spend a further year after the final examination working up some special field, on which they produced a thesis, which had to be approved before the degree was granted. The average standard of these theses was surprisingly good, and the subject, in some instances, provided the new graduate with a field into which he could enter with some confidence for further study.

Leathes was elected to the Physiological Society in 1895, and in 1952 was accorded the distinction of honorary membership. He served for three periods on its committee, and for ten years as an editor of the *Journal of Physiology*. This latter service, often now forgotten, was perhaps his best contribution to British physiology, for he took infinite and unsparing pains in helping authors, young and old, who lacked the ability to express themselves clearly. As he was in Toronto when the Biochemical Society was formed in 1911, he happened not to have been an original member, but he joined it in 1913.

In 1921 he was elected a fellow of the Royal College of Physicians, and gave the Croonian Lecture in 1923; it dealt with fat metabolism in various aspects, and in its relation to cellular structure and functions. He also gave the Harveian Oration in 1930, on "The Birth of Chemical Biology". Other honours included the D.Sc. Sheffield in 1933, and Manchester 1936, and the honorary fellowship of New College, Oxford.

Leathes was essentially a modest and scholarly man, of kindly and phlegmatic disposition, one of the few physiologists with a classical education, and a good linguist; he began the study of Russian at the age of eighty. Tall and wiry, he was, even at that age, good for a brisk walk of ten miles or more. Among other accomplishments, he was a pastellist of discernment, despite his high degree of myopia, or perhaps even on account of it, as he was unaware of much landscape detail which tends to distract the amateur. After his retirement he moved to Wantage, and worked in the Physiological Laboratory at Oxford, with John Mellanby. Their published work, which was interrupted by the Second World War, dealt with thrombokinase, and with the action of lecithin upon it. He then moved successively to Lyme Regis, London, Southbourne, and finally to Switzerland, near the scene of some of his happier early years.

Leathes spent his life largely in helping others by patient and unselfish acceptance of responsibilities which brought no ponderable reward—service on the Council of the Royal Society, 1924–26, on the Medical Research Council, 1928–31, the General Medical Council, 1919–38, and on its Education Committee, of which he was chairman in 1931. But he will long be remembered with affection by many friends and pupils.

C. Lovatt Evans

Dr. A. E. J. Vickers

Dr. A. E. J. Vickers, who died suddenly on September 8 at the age of fifty-eight, was director of research at the Thermal Syndicate, Ltd., Wallsend, Northumberland, a position he had held since November 1947; he was elected to the Board of Directors in April 1953. His early academic education began with training in 1915 in Sheffield for the teaching profession; but, probably influenced by war work in a munitions factory, he decided to make chemistry his future profession and, following study in Stoke and London, took an external London B.Sc. in chemistry in 1922.

He then joined the late Dr. J. W. Mellor, of the British Refractories Research Association (now the British Ceramic Research Association), Stoke-on-Trent, where he developed an interest in mineralogy, and in 1927 he took the post of chief chemist to Buxton Lime Firms Co., Ltd. (now the Lime Division of Imperial Chemical Industries, Ltd.). Two years later Dr. Vickers moved to the Billingham works of Imperial Chemical Industries, Ltd., and continued investigations in the problems of refractories and in mineralogy, gaining his Ph.D. in 1935 with a thesis on the colloidal properties of clay. During the latter part of his stay at Billingham he was in charge of research on ceramics, mineralogy and physical methods, including a variety of applications of spectroscopy and microscopy, and when he moved in 1947 to the Thermal Syndicate, Ltd., his work continued to be largely in the field of ceramics, but at higher temperatures than heretofore.

Dr. Vickers was keenly interested in the work of scientific and technical societies, including the Royal Institute of Chemistry, the Society of Glass Technology and the Society of Chemical Industry, and he was a founder member of the Institute of Ceramics. He was also very much concerned with higher education, being a member of the council of St. John's College in the University of Durham. Apart from his professional work, Dr. Vickers was a keen photographer, gardener and musician, and he was an active member of the Anglican Church. He is survived by his wife and by a son and a daughter, training respectively for the medical and dental professions.

Prof. B. M. Duggar

Benjamin Minge Duggar, botanist, mycologist, plant physiologist, plant pathologist and microbiologist, who died at New Haven, Connecticut, in mid-September, a fortnight after his eighty-fourth birthday, had a long and varied career. After holding posts in his native state of Alabama and elsewhere, Duggar became professor of botany in the University of Missouri in 1902. Afterwards he was professor of plant physiology first at Cornell (1907–12) and then in the University of Washington (1912–27), from where he moved to the University of Wisconsin as professor of plant physiology, plant pathology and economic botany (1927–43). Finally, in 1944, he became consultant on mycological research and production to the Lederle Laboratories Division of the American Cyanamid Co.

Although during recent years Duggar became widely known for the part he played in the discovery and development of the antibiotic aureomycin, his name is not associated with any one particular topic. Duggar's distinction lies rather in the breadth and vigour of his interests and his lively appreciation of the novel. Throughout his working life he was always to be found actively engaged in the front line of botanical advance and he made notable contributions in many fields.

After an undergraduate period in Alabama and Missouri, Duggar visited universities in Germany (where he was presumably influenced by the 'new botany'), France and Italy, and some of his early publications related to cytological and anatomical studies on pollen development in *Bignonia* and members of the Araceae. Then he turned to plant physiology, on which he wrote later a text-book ("Plant Physiology, with Special Reference to Plant Production", 1911). During the nineteen-twenties, virus diseases of plants claimed his attention (when the results of his very pertinent studies led him to inspired speculation on the nature of the infective agent) and in 1936 he edited for McGraw-Hill the two-volume "Biological Effects of Radiation".

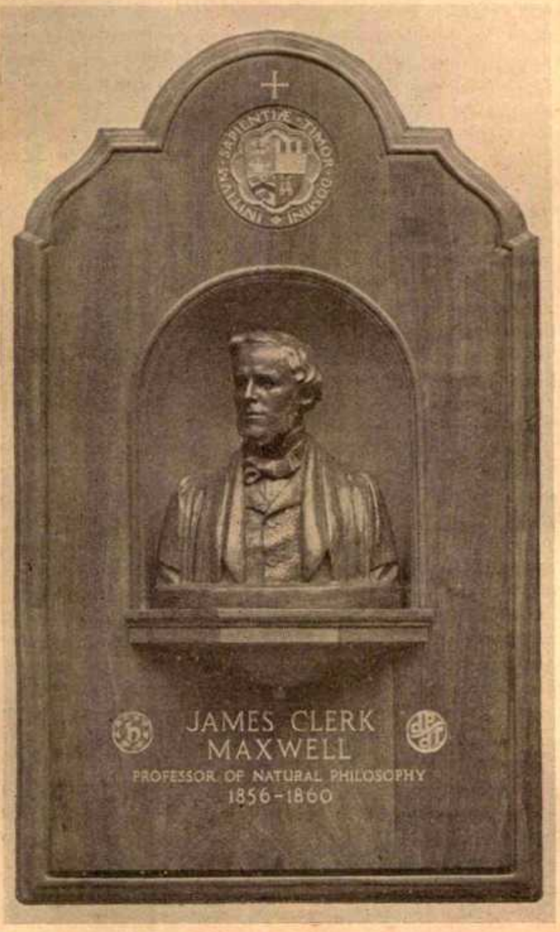
Duggar's first publication (1892) was on teleutospore germination of a rust and he maintained an interest in fungi throughout his life. Possibly, it is by his contributions to mycology and mycological plant pathology that he will be best remembered. While on the staff at Cornell he worked on diseases of fruit and vegetables and in 1909 published "Fungous Diseases of Plants", an important work which was a standard text-book for the succeeding decade and which is still remarkable for its blend of the scientific and the practical and for its modern approach. On the academic side, Duggar made contributions to an understanding of spore germination, and his physiological studies on fungi may be considered to have culminated in a well-known series of papers published in the *Annals of the Missouri Botanical Garden* (1916–19).

G. C. Ainsworth

NEWS and VIEWS

James Clerk Maxwell : Memorial at Aberdeen

A memorial panel to James Clerk Maxwell, by C. d'O. Pilkington Jackson, was unveiled in the Mitchell Hall, Marischal College, Aberdeen, by Sir George Thomson, master of Corpus Christi College, Cambridge, on October 15. The central feature is the bronze portrait bust showing Clerk Maxwell as a young man, under thirty, when he was professor of natural philosophy in the University of Aberdeen during 1856–60. The two devices flanking the inscription are the sign for Saturn, enclosed by a laurel wreath, which refers to the paper on the "Stability of Saturn's Rings" for which Clerk Maxwell was awarded the Adams Prize at Cambridge in 1857, and the thermodynamics formula $\mathrm{d}p/\mathrm{d}t = JCM$, which he used as a pun on his name.



INITIUM SAPIENTIÆ TIMOR DOMINI
JAMES CLERK MAXWELL
PROFESSOR OF NATURAL PHILOSOPHY
1856-1860

Clerk Maxwell was appointed professor of natural philosophy at Marischal College, Aberdeen, at the age of twenty-five. When the fusion of Marischal College and King's College took place in 1860, under the Universities (Scotland) Act, 1858, the two chairs of natural philosophy in Marischal and in King's were combined, like other duplicated chairs, and Prof. David Thomson of King's, being the senior, occupied the single chair, and Clerk Maxwell, not yet thirty, was retired on a pension for life. In the summer of 1860 he was appointed professor of natural philosophy in King's College, London, where he remained until 1865, when he retired to an estate which he had inherited from his father at Glenlair, in Galloway, to prepare his "Treatise on Heat" (1870) and "Electricity and Magnetism" (1873). In 1871 he was appointed to the new chair of experimental physics at Cambridge, where he designed and superintended the erection of the Cavendish Laboratory.

Agricultural Botany in Reading : Prof. A. H. Bunting

Dr. A. H. Bunting has been appointed professor of agricultural botany in the University of Reading, as from October 15, in succession to Prof. D. W. Goodall (*Nature*, 173, 894 ; 1954), who has been appointed director of the new Tobacco Research Institute of the Australian Commonwealth Scientific and Industrial Research Organization established in North Queensland. Prof. Bunting, who is thirty-nine, was born in South Africa, and graduated at the University of the Witwatersrand in 1937. He then proceeded as a Rhodes Scholar to Oxford, where work on the respiratory enzyme systems of barley led to the degree of D.Phil. The war years were spent at Rothamsted Experimental Station, where his principal concern was with sewage sludge as a soil amendment. After a short period of work for the Medical Research Council, he proceeded to Tanganyika, where he organized scientific research in connexion with the ill-fated groundnut scheme of the Overseas Food Corporation. When the scheme was wound up, Prof. Bunting moved to the Sudan, where he took responsibility for setting up a new research station at Tozi, with the view of developing field crops in that area. Prof. Bunting's wide experience in large-scale field experimentation, and in applied plant physiology and ecology, should stand him in good stead in his new post at Reading. It should also ensure the continued broadening of his Department's interests which has been apparent in recent years. There is little doubt that tropical crops and conditions will occupy a prominent place in the teaching programme under his leadership, and one may expect the Department to continue as a valuable nursery for workers in agricultural research overseas.

The Kalinga Prize: Prof. George Gamow

The Kalinga Prize for the popularization of science, offered annually by the United Nations Educational, Scientific and Cultural Organization, has been awarded for 1956 to Prof. George Gamow, of the University of Colorado at Boulder. The Kalinga Prize, presented by Mr. B. Patnaik, a director of a foundation for the economic, social and cultural progress of the Indian State of Orissa, is valued at £1,000. Prof. George Gamow was born on March 4, 1904, at Odessa, and became an American citizen in 1939. He studied physics at the University of Leningrad and later was associated with the Institute of Theoretical Physics of the University of Copenhagen, the University of Cambridge and the Institut Pierre Curie in Paris. He also served as a professor at the University of Leningrad. After having taught physics during 1934–56 at the George Washington University at Washington, D.C., Prof. Gamow has just been appointed professor of physics at the University of Colorado at Boulder. Prof. Gamow is serving or has served as scientific adviser to a number of major organizations, including the Bureau of Ordnance, Department of the Navy; the Applied Physics Laboratory and the Operational Research Office of Johns Hopkins University; the Los Alamos Scientific Laboratory and the Radiation Laboratory of the University of California; the Air Force Scientific Advisory Board; and Convair, San Diego, Cal. He is well known for his scientific research, which has led to more than a hundred publications in such fields as the theory of radioactive decay and a model of an atomic nucleus, relativistic cosmology and the origin of chemical elements, and the theory of protein synthesis. Prof. Gamow, however, has not devoted his scientific career solely to research and teaching. He has also become well known as the author of some ten books and a large number of articles in the field of science popularization. Although they often treat such subjects as the theory of relativity or the quantum theory, his works combine an accurate presentation of scientific facts with an easy, good-humoured style.

Mellon Institute of Industrial Research, Pittsburgh: Dr. P. J. Flory

Since the retirement earlier this year of Dr. E. R. Weidlein as president of the Mellon Institute of Industrial Research, Pittsburgh (see *Nature*, April 21, p. 733), a new post has been established, that of executive director of research, and Dr. Paul J. Flory, professor of chemistry and acting chairman of the Department of Chemistry, Cornell University, has been appointed the first holder. The post carries the responsibility of guiding the whole field of investigation in the Institute, and for this Dr. Flory is very well suited, his career to date being divided almost exactly between academic and industrial research. After graduating from Manchester (Ind.) College, followed by postgraduate work in physical chemistry at the Ohio State University, Dr. Flory spent four years (1934–38) in research on synthetic fibres, synthetic rubbers and other polymeric substances at the duPont Experimental Station, Wilmington, Del. For the next two years he was engaged in teaching and research in the Basic Science Laboratory of the University of Cincinnati, and then, during 1940–43, was a research chemist with the Standard Oil Development Co., Elizabeth, N.J. Following this, he was head of fundamental research for the Goodyear Tire and Rubber Co., Akron, Ohio, and then in 1948 he went to Cornell University to direct graduate research in polymer chemistry. Dr. Flory's book, "Principles of Polymer Chemistry" (1953), is an authoritative work in this field. Besides his work on high polymers, however, he has carried out investigations in photochemistry, chemical reaction kinetics, thermodynamics and statistical mechanics. Dr. Flory is a member of the National Academy of Sciences and holder of the Joseph Sullivant Medal (1954) of the Ohio State University, the Leo Hendrik Baekeland Award (1947) of the American Chemical Society, and the Colwyn Medal (1954) of the Institution of the Rubber Industry (Great Britain).

Perkin Centenary Celebrations in Bradford and Leeds

The West Riding Section of the Society of Dyers and Colourists will be celebrating during October 31–November 3 the centenary this year of W. H. Perkin's discovery of the dyestuff mauveine. The celebrations will commence with two lectures: the first will be given on October 31 at 7.30 p.m. by Prof. John Read in the Hotel Metropole, Leeds, his subject being "The Life and Work of Perkin"; and on the following day, also at 7.30 p.m., Dr. C. M. Whittaker will give a lecture in the Victoria Hotel, Bradford, on "Early Stages in the Renaissance of the British Dyemaking Industry: Tales from Turnbridge, Huddersfield, 1899–1920". During November 1–3 an exhibition will be held in the Technical College, Great Horton Road, Bradford, which will illustrate the developments in dyestuffs and closely related products from the time of Perkin's discovery of mauveine to the present day and also the modern uses of dyestuffs. On November 2 the West Riding Section will hold a dinner and dance in the Victoria Hotel, Bradford. Further information on all these events can be obtained from the Society of Dyers and Colourists, 19 Piccadilly, Bradford 1.

Royal Society Antarctic Expedition

The Royal Society announces that the War Office has agreed to the appointment of Colonel Robin Smart as leader of the main party of the Royal Society International Geophysical Year Antarctic Expedition until January 1958. The main party of about twenty will leave London Docks on

November 15 in the *Magga Dan*, which is being shared with the Trans-Antarctic Expedition, and will arrive at Royal Society Base, Halley Bay, at the end of December 1936. They will relieve the advance party of ten men who sailed in the M.V. *Tottan* from Southampton on November 22, 1955, under the leadership of Surgeon Lieutenant-Commander David Dalgliesh. The main party will install the scientific equipment and erect huts so that the station is fully operating at the commencement of the International Geophysical Year on July 1, 1957. Colonel Smart will return to the United Kingdom at the beginning of January 1958; but the main party will remain at Halley Bay until the end of the International Geophysical Year on December 31, 1958. Colonel Smart, who is at present deputy director of Army health, Western Command, Chester, is forty-two years old. He graduated in medicine in the University of Aberdeen in 1936 and was commissioned into the Royal Army Medical Corps in the same year During 1948–49 Colonel Smart was a member of a War Office team working in the Arctic region of Canada and he returned to Northern Canada and Alaska in 1950.

An Optical Astronomy Observatory for the University of Michigan

A grant of 545,000 dollars has been made to the University of Michigan by the National Science Foundation, Washington, D.C., for the support of studies leading to the establishment of an optical astronomy observatory. The studies are under the direction of Dr. Robert R. McMath, director of the McMath–Hulbert Observatory, and are a continuation of work undertaken last year by the University with the aid of previous grants totalling 300,000 dollars from the Foundation. The most recent grant to the University includes 30,000 dollars for a study leading to the erection of a solar telescope. The establishment of an optical astronomy observatory will include initially a 36-in. and an 80-in. telescope, and work so far has consisted of a search for a suitable site, the design and erection of equipment to test the sites, and work on the 36-in. telescope. The optics for this telescope are nearing completion at Yerkes Observatory. The test equipment consists of a 'seeing' tower which is erected on potential sites for the purpose of gathering data that will help guide the astronomers in selecting a spot where an observatory can operate with maximum efficiency. The tower is a triple-shelled steel structure, 60 ft. in height, equipped with a telescope that continually measures the turbulence in the atmosphere by gauging the size of the image of the star Polaris. This information, along with wind and temperature data, is transmitted to recording instruments situated at the base of the tower. The tower will make these automatic recordings over a period of more than eighteen months. The search for a site has now been reduced to approximately five sites, all of which are situated in the south-western United States because climatic and atmospheric conditions there are favourable and because it is one of the few remaining areas in the United States where an observatory can be erected a sufficient distance from the light and dust generated by cities. Four sites at present under study are Kitt Peak (6,800 ft.) in southern Arizona, the Sierra Ancha region (7,500 ft.) in central Arizona, Chevelon Butte (6,900 ft.) in northern Arizona, and the Hualpai region (7,400 ft.) in north-western Arizona. The Kitt Peak site is of special interest because it is on the Papago Indian Reservation. The mountain is sacred to the Papagos and the Papago Tribal Council granted special permission for the erection of a 'seeing' tower. Similar towers will be erected on other sites, including the Junipero Serra, California.

European Bison from Poland

Through the Forestry Commission, Poland has generously presented to the United Kingdom a breeding pair of European bison. They arrived on October 9 and are in the London Zoo for a period of quarantine; afterwards they will be on show to the public and may later be transferred to Whipsnade. European bison are rare forest animals and, until the arrival of the pair from Poland, the Zoological Society had none in its care. Poland has between eighty and ninety European bison, representing, it is understood, a substantial proportion of world stocks; the pair now in Britain are from a reserve near Cracow.

Bristol Museum

That the Bristol Museum plays an energizing part in the cultural life of the city and surrounding county is shown in the report of the city's Museum Committee for 1955. Although the main activities of the Museum are linked to the permanent exhibits, fifteen major temporary exhibitions were also arranged; these ranged from geology as illustrated by railway posters to a collection of postage stamps issued in the nineteenth century. A special feature is arranged each month to show either objects on loan or recently given. The city archivist has provided material each quarter for a special case while the city librarian exhibits local documents of topical interest. The Bristol Society of Architects has devised illustrations which enable visitors to understand and appreciate the principles of architecture, examples being drawn from the locality. As in previous years, six lectures have been provided during the winter months to audiences of more than three hundred at each session. Conducted summer walks have again been arranged, some of the walks attracting so many visitors that they have been embarrassing to conduct. The staff of the Museum was again invited to give many lectures to various organizations, while an interesting development was the loan of small assemblages of zoological and botanical material to H.M. Prison at Falfield. Classes from all types of schools have visited the Children's Room. The demands in history and natural history are now approximately equal; but although the room is in constant use during term-time, requests exceed the number which it is possible to accommodate. The Saturday Nature Club, now more than a year old, has been enthusiastically attended by 50–60 members each week, chiefly older primary school children. This is a record of which Bristol Museum might well be proud and should serve as a model for other areas.

Trinidad and Tobago Forest Department: Report for 1954

The annual report for 1954 of the Trinidad and Tobago Forest Department (pp. 44+1 map. Trinidad: Government Printing Office, 1955; 36 cents) gives a statement of the present areas of forestry in the Islands. Their total area amounts to 1,863 and 116 square miles, respectively, practically all of which is below a thousand feet. In Trinidad and

Tobago forest reserves now cover 279,996 acres, or 22 per cent of the country. To this about 65,000 acres of hill forest will be added when the surveys have been completed, bringing the total to 27 per cent. Adjustments are probable later, and it is assumed that the forest estate will eventually be about 300,000 acres—a very satisfactory area for the Islands. Of this area, 64,000 acres have been allocated to the plantation programme, mainly teak (an exotic, of course), and about 100,000 acres, parts of which have not yet been declared forest reserves, may be found to be inaccessible for a long period. Swamps cover a certain amount of area. Thus there are 128,000 acres of accessible forest to be regenerated under systems other than teak and mixed hardwood plantations. In the north a natural regeneration programme is in force over 31,800 acres, which will be treated under the shelter-wood system. In general, the forest management in the Islands may be considered to be in a satisfactory state.

André Mayer Fellowships of the Food and Agriculture Organization

The United Nations Food and Agriculture Organization has established a number of fellowships for advanced training in preparation for research work in topics of particular interest to member countries and to the Organization as a whole. Five or six fellowships are being offered this year, spread over the whole field covered by the Organization, namely, agriculture, agricultural economics and statistics, fisheries, forestry and nutrition. They will be called André Mayer fellowships in memory of the late André Mayer, who was closely associated with scientific research in France as well as international work, particularly in relation to the Organization. The awards will be for periods up to two years, with the possibility of an extension to a maximum of thirty months, and payment will be about 250 dollars a month. Further information can be obtained from the Secretariat of the F.A.O. National Committee for the United Kingdom, c/o Ministry of Agriculture, Fisheries and Food, 10 Whitehall Place, London, S.W.1.

Scottish Postgraduate Scholarships in Agriculture

The Department of Agriculture for Scotland has awarded the following postgraduate scholarships in agricultural subjects, tenable for periods up to three years at the institution shown: *Husbandry*, R. C. Kirkwood (University College of Wales, Aberystwyth), A. McKechnie (University of Reading), and J. L. Beveridge, S. S. Fluss and C. G. M. Duncan (University of Cambridge); *Engineering*, D. A. Jack (King's College, Newcastle upon Tyne). The awards held by the following, all of which are in husbandry, are being continued for a further period: A. D. Drysdale (University of Minnesota), D. M. S. Livingston (University of Aberdeen), C. Smith (Iowa State College), R. A. N. Napier (University of Edinburgh), J. Frame, I. C. Beattie and W. C. Smith (Massey Agricultural College, New Zealand), and N. C. Lawson (Macdonald College, McGill University).

Announcements

Major C. W. Hume, director of the Universities Federation for Animal Welfare, which he founded originally in 1926 as the University of London Animal Welfare Society, has been awarded the Albert Schweitzer Medal of the American Animal Welfare Institute.

Dr. R. Lessing has been elected president of the National Smoke Abatement Society in succession to Sir Ernest Smith.

The following appointments in the University of London have been announced: Mr. P. V. Danckwerts, deputy director of research and development of the Industrial Group, Atomic Energy Authority, to the University chair of chemical engineering science tenable at the Imperial College of Science and Technology; Dr. H. Tropper, senior lecturer at Queen Mary College, to the University readership in electrical engineering tenable at that College.

Dr. D. Starkie, director of research at the Hosiery and Allied Trades Research Association, is relinquishing his appointment in order to join the Board of English Rose, Ltd., as director of research in charge of the newly created Department of Research. Dr. Starkie will head a team of experienced scientists and technologists and will be concerned with research on hose materials, machines and products.

The sixth George Scott Robertson Memorial Lecture, given under the auspices of the Ministry of Agriculture, Northern Ireland, will be delivered in the Sir William Whitla Hall of The Queen's University, Belfast, at 3 p.m. on October 26, by Dr. D. P. Cuthbertson, director of the Rowett Research Institute, Aberdeen. The subject will be "Animal Nutrition in relation to Production and Disease". The Lecture will be open to the public.

The programme of lectures for 1956–57 of the Bedson Club, King's College, Newcastle upon Tyne, is as follows: October 26, modern inorganic stereochemistry, by Prof. R. S. Nyholm; November 16, the chemistry of some naturally occurring polyacetylenes, by Prof. B. Lythgoe; and January 25, polymerization in heterogeneous systems, by Prof. C. E. H. Bawn.

The first meeting of the British Society for Immunology will be held at the Wellcome Foundation, 183 Euston Road, London, N.W.1, during November 9–10. Following introductory remarks by Sir Henry Dale, the meeting will consist of the reading of scientific papers, the afternoon of the first day being devoted to a symposium on "Complement". Further information can be obtained from Prof. G. Payling Wright, Department of Pathology, Guy's Hospital Medical School, London, S.E.1.

The Morcom Green, Edwards Prize, which is offered yearly through the New Zealand Institute of Chemistry for the encouragement of original research by younger chemists, has been awarded this year to I. R. C. McDonald, of the Dominion Laboratory, Department of Scientific and Industrial Research, New Zealand, for his work on methods for the analysis of insecticides used in agriculture. Mr. McDonald has been engaged in the analysis of complex organic mixtures, with particular emphasis upon wool fat, insecticidal mixtures and wood chemistry, and has developed original techniques, using a double-beam infra-red spectrophotometer, for determining accurately the proportions of the toxic substances present in insecticide formulations.

Erratum. In *Nature* of August 4, p. 240, it was stated that Dr. F. Körösy had been appointed professor of physical chemistry in the Technion–Israel Institute of Technology, Haifa; he has, in fact, been appointed research fellow in physics at the Technion.

PHYSIOLOGICAL AND CELLULAR ASPECTS OF AGEING

A VARIETY of interesting papers were read at a joint meeting of the Dutch Society of Gerontology and the British Society for Research on Ageing, held at the Antoni van Leeuwenhoek-Huis (Netherlands Cancer Institute), Amsterdam, on July 27 and 28. Included in the programme were papers by guest speakers from the United States, Canada and South Africa.

One of the difficulties in studying morphological or physiological changes with old age has been that of distinguishing between fundamental alterations due to senescence and changes due to the operation of secondary factors, for example, nutrition. Dr. J. J. Groen, of Amsterdam, described a condition, 'senile' paradentosis, which might have been thought at first to have been in either category. This condition is characterized by resorption of the alveolar bone of the tooth sockets, usually accompanied by retraction of the gingiva; it is progressive and leads eventually to loss of teeth and to extensive atrophy of the jaw. The condition may begin in the young or middle-aged. Another condition well known in old people is senile osteoporosis, particularly in the spine and pelvis. This condition is clinically recognizable by X-rays; but it produces remarkably few metabolic changes. The phosphorus, calcium and phosphatase of serum of such patients seem to be unchanged, and the cause of the condition has been the subject of much speculation. Until recently, osteoporosis has been recorded by physicians and paradentosis by dentists—but Dr. Groen believes that they are one and the same disease. His investigations showed that all those suffering from one of them were found upon investigation to be suffering also from the other.

The etiology of this complaint was investigated at some length; but only one constant factor could be found—in all cases the patients were people who had stopped taking milk at an early stage in their lives. Investigation of their diets, which seemed adequate in most nutrients, showed a calcium intake between 250 and 450 mgm. per day. A few patients on whom balance studies were done while they were on their 'home diet' had negative calcium balances of 50 to about 200 mgm. a day. Control individuals who drank a pint to a quart of milk a day showed scarcely any sign of paradentosis or of osteoporosis at an advanced age.

Dr. Groen pointed out that Allbright had thought that osteoporosis in old persons was due to a decrease in sex hormones; but his own investigations had shown that the disease can occur before the menopause, and is invariably associated with a long-protracted low intake of calcium. He believes, in fact, that the condition 'paradentosis–osteoporosis' is mainly a result of a chronic, low-grade calcium deficiency.

Dr. T. Gillman, of South Africa, also recorded the syndromes of many nutritional conditions met with in South Africa among native populations. These included kwashiorkor, pellagra and an accumulation of iron in the liver which was sometimes followed or accompanied by fibrosis; he stressed the significance of his results in the study of gerontology.

Clinical studies on blood pressure by Dr. M. Landowne, of Bethesda, using intra-arterial recording, showed that the systolic pressure increases by an average of 4·8 mm. of mercury or 4 per cent per decade. This is the momentary peak pressure; but the average increase of the entire systolic period is 2·8 mm. mercury or 2 per cent per decade. There is also a decreased cardiac output of 1 per cent per year due partly to decrease in the blood pumped by each beat. Portion of this decrease is effected by a slowing of the heart. Just as in training for athletic activities the heart-rate slows, so in old age it slows as an adaptive change, for by so doing there is a large diastolic filling period, thus providing a better stroke/volume than if the diastolic pressure was shortened.

Dr. R. Van Zonneveld, of Gröningen, described a survey of old persons in the Netherlands which began with an inquiry among the old people themselves as to how they felt and what infirmities they complained of. This is to be followed by an announcement of the details of a survey which will be carried out in collaboration with twenty-four regional teams of doctors.

The question of whether sex hormones are invariably decreased in old age was discussed by Dr. O. Mühlbock, of the Netherlands Cancer Institute, on the basis of his work on highly inbred mice. Frequently in old female mice an enormous hypertrophy of the uteri is observed. It was found that the œstrogenic hormones maintaining this uterine development are produced by the ovaries. These old ovaries show few follicles; but cells can be seen in the periphery, obviously coming from the germinal epithelium, which look very like granulosa cells. They penetrate into the ovarian stroma forming small anovular follicles which are probably the source of at least some of the female sex hormone. In some cases the adrenals too may contribute œstrogens in old mice. In old adrenals so-called 'A' cells develop just under the cortex. These cell groups may show adenomatous development, and in this case probably also produce œstrogens.

In some animals there is also an enormous development of the mammary glands. This may be in part due to female sex hormones, but also to the high production of prolactin by the old pituitary. It was found that these mice often had pituitary tumours of a similar nature to those which can be produced in younger animals by prolonged œstrogen treatment. These pituitary tumours contain no gonadotrophin, growth hormone or corticotropin, and only a little thyrotrophic hormone. A high prolactin activity is, however, regularly found.

These studies emphasized that hormone imbalance may occur in old age, leading to endocrine hyperactivity rather than inactivity in some cases, and that this appears to be genetically determined.

Kidney studies of old rats by Dr. and Mrs. Friedman, of Vancouver, also demonstrated endocrine changes in old animals. In this case it is apparently decreased neurohypophysial function which is responsible for their results. They found that both young and old animals appear to excrete sodium identically, but that the older animals excrete a much more watery urine which suggests a decrease of the tubular water-absorption mechanism. If 'Pitressin' is given to the old animals with the saline solutions used in producing a salt load on the kidneys, re-absorption of water becomes the same as in the young animals, although sodium re-absorption was a little less. The neurohypophysis was shown to be unresponsive to direct osmotic stimulus in the old rat.

Cellular and tissue studies in old age were described by Dr. P. J. Thung, of the Netherlands Cancer Institute, Dr. G. H. Bourne, of London, and Dr. H. Saxl, of the Department of Medicine, Leeds.

Dr. Thung's paper dealt with amyloidosis in senile mice. He pointed out that mice easily develop amyloid, which may be produced experimentally in response to injection of a wide variety of substances and even by a milk and cheese diet. In old age, however, untreated mice similarly often develop amyloid. Genetical factors appear to be of prime importance in this tendency to amyloid degeneration, both experimentally and spontaneously, as some strains are rarely affected whereas others may show a 100 per cent incidence. Many of the substances which in mice cause amyloid, in the rat produce only necrosis and fibrosis. Similarly, it was found that chronic alcoholism, which in man would be expected to lead to liver cirrhosis, in mice caused heavy degrees of amyloidosis of the liver.

In human pathology it is increasingly recognized that amyloid degeneration is far more frequent than the classical condition found secondary to chronic suppurative disease. Its various forms range from this secondary amyloidosis to the amyloid found in cases of rheumatoid arthritis and the amyloid infiltrations frequently observed in the cardiac muscle in old age. These forms apparently represent different varieties of a common derangement of protein metabolism, on the causes of which as yet little is known. In mice, however, this derangement occurs much more easily than in man, and the causative agents consequently are less specific. Among these, old age plays an important part.

Dr. G. H. Bourne described the principal changes that take place in cells as they age, and directed attention to the fact that in many organs in old animals there is a histochemical increase in the activity of phosphatases and esterases and that biochemical studies have recorded an increase in activity of other hydrolytic enzymes. It may be that this increase in hydrolytic enzyme activity, which is destructive of many esters essential in metabolic activities, is one of the fundamental changes taking place in ageing cells.

The question of a possible link between protein and polysaccharide involvement in arteriosclerosis and lipid metabolism was discussed by Dr. H. Saxl, of the Department of Medicine, Leeds. She suggested the following mechanism by which the tissue polysaccharides *in situ* and certain components of the serum form an anti-lipæmic system: (*a*) in the presence of elastase, and especially the fraction which appears to have elasto-mucase activity, the mucopolysaccharides are made soluble and unstable; (*b*) the action of the serum inhibitor is to inhibit the removal of the soluble polysaccharides and by a direct action on these to make them stable and orthochromatic, and either secondarily or as a result of this interaction to activate a lipase.

An examination of the mode of the lipolytic action on atheromatous arterial walls has shown that there appear to be a degradation of neutral lipids of the atheromatous plaques and liberation of the soluble acid fats, which diffuse in the tissues.

G. H. BOURNE

CHEMISORPTION

SYMPOSIUM AT KEELE

A SYMPOSIUM on chemisorption was held by the Chemical Society during July 16–19 in the University College of North Staffordshire, Keele. The symposium, which was organized by Prof. W. E. Garner, was divided into five sections, the first of which dealt with the theory of chemisorption, with Prof. Garner as chairman. D. A. Dowden (Billingham) gave a general review of the covalent aspects of adsorption, extending the usual classification of *sp* and *d* bonds from metals to semiconductors. He considered that adsorbed gases could either be held strongly on the intermetallic type of *dsp* orbitals, or more weakly on atomic *d* orbitals. Using the ideas of crystal field theory, he indicated how the d^3sp^2 orbitals of a surface metal atom might split to give a d^2p set for the underlying metal and a *dsp* orbital in the surface. He did not consider that the surface metal atoms exhibit *dsp* free valencies, but emphasized the role of *dz* orbitals in weak adsorption. T. B. Grimley (Liverpool) used the *L.C.A.O.* or tight-binding approximation to discuss the interaction of a hydrogen atom with an electron in a surface state of the metal. Where a singly occupied surface state or partly occupied *d*-band is available, a bond is to be expected, the hydrogen atom being located over the metal atom. J. H. de Boer (Geleen) gave a critical account of theories relating heat of adsorption to surface coverage, and contact potential. He considered particularly the cases of cæsium on tungsten and hydrogen on nickel. The deficiencies of the simple double-layer theory were described and then improvements, allowing for discrete layers and mutual depolarization of dipoles, were tried. The conclusion reached was that some heterogeneity was present even with cæsium on tungsten. G. C. A. Schuit, L. L. van Reijen and N. H. de Boer (Amsterdam) described thermodynamic data for the adsorption of hydrogen on nickel supported on silica, and other supported transition metals. Definite evidence for heterogeneity was deduced, and experiments on the hydrogen–deuterium exchange showed the existence of a few sites specially active at 77° K. In the discussion, the thought was expressed that the silica support might in some way be contributing to the heterogeneity observed.

The next section dealt with chemisorption on insulators, and the chair was taken by D. A. Dowden. J. J. Kipling and D. B. Peakall (Hull) described results on the adsorption of liquids on silica gel and alumina. Four tests were made to distinguish chemisorption from physisorption: irreversibility; time effects; evidence for reaction at specific sites; and the relation of extent of chemisorption to the number and nature of active groups in the surface. S. J. Gregg (Exeter) described how some water was retained by active oxides even at the highest temperatures, probably hydroxyl groups. A second variety of adsorption, probably involving molecular water that was hydrogen-bonded to the surface, was indicated by the failure of desorption isotherms to close with the adsorption isotherms even at the lowest pressures. The presence of some hydroxyl groups appears essential for this type of adsorption. If silica is heated to 600° C. it becomes hydrophobic, showing a type V isotherm, but becomes hydrophilic when exposed until half saturated with water vapour. A. Kloosterziel (Amsterdam) described results on the interchange of deuterium atoms between alumina containing deuterium and ethylene. His kinetic analysis was developed in great detail for a number of possible models, to give the distribution of deuterium over the ethylene molecules as a function of time of contact. His conclusion was that, in the exchange process, two ethylene molecules require to be adsorbed at one site, probably an Al^{3+} ion. Subsequent discussion on these papers brought out the fact that physical and chemical adsorption frequently overlap in energy and that it is undesirable to try to draw too firm a dividing line.

The third section dealt with chemisorption on metals, and the chair was taken by Prof. D. D. Eley. B. M. W. Trapnell (Liverpool) reviewed his recent work on evaporated metal films and showed how heats of adsorption of oxygen and hydrogen on a range of metals may be related by a single numerical factor. A correlation of adsorption heats with atomic number for a series of metals appears to be more satisfactory than a correlation with *d*-character. This he related to the properties of the free atom, the states of which, he suggested, resemble the surface states of a bulk metal. The reactivity of gold and mercury in oxygen chemisorption so far stands outside all such schemes. He outlined new data on velocities of chemisorption on ten metals, and related them to exchange velocities of hydrocarbons (W, Rh > Pd > Ni > Fe). R. Suhrmann (Hanover) reviewed his results on changes in electrical resistance brought about by adsorption of gases on thin films of nickel and bismuth, the latter metal being chosen since its films show semiconducting properties. As an example of his work, he found that hydrogen on adsorption increases the resistance of nickel films at 90° K. On bismuth hydrogen effects only a very small decrease of resistance, attributed to a polarization $H_2^+ \,..\, Bi^-$. The paper by J. C. P. Mignolet (Liège) dealt with the problem of charge transfer in physical adsorption, as revealed by the author's extensive results on contact potential changes brought about by adsorbed gases. Thus in a case like nickel–xenon (0·85 V.) he concluded that the *d*-orbitals of the nickel are the acceptor orbitals. Where these are not present, smaller effects are observed, for example, zinc–xenon (0·21 V.). The method may be used as a diagnostic test for empty surface *d*-orbitals and reveals their presence in copper, since copper–xenon is 0·67 V. G. C. Bond and J. Addy (Hull) described results on the addition of deuterium to cyclopropane. The distribution function for deuterium in the products is considered to give a measure of the catalytic activity, the metals in descending order being rhodium, iridium, platinum, palladium, nickel. The paper by D. D. Eley and D. R. Rossington (Nottingham) gave a kinetic analysis of the parahydrogen conversion on a copper film which led to a value of 8 kcal. for the heat of chemisorption. Apparent frequency factors and activation energies were determined for copper, silver and gold catalysts in the form of foil, film and wire. The apparent activation energies were constant for a given metal, but the frequency factors increased in the order: foil, film, wire. The results for the three metals fell on a logarithm (frequency factor)—*E* relation that is characteristic of the catalyst type. The paper by P. M. Gundry and F. C. Tompkins (London) dealt with the slow adsorption of hydrogen and carbon monoxide on nickel. They found the Elovich equation applicable, and proposed a model of a homogeneous surface, with sites of strong adsorption reached via precursor sites of weak adsorption, linking up with Dowden's *d*-orbital model. J. H. Leck (Liverpool) described the effects of positive ion bombardment on metal surfaces. The positive ions were found to penetrate the surface to a depth of several atoms. In the discussion, D. J. C. Yates (Cambridge) outlined infra-red evidence for the loss of rotations by methane on adsorption on silica.

Prof. W. F. K. Wynne-Jones took the chair for the fourth section, which considered chemisorption on carbon. D. J. E. Ingram (Southampton) described the application of the electron resonance technique to the problem of carbonization. There is clear evidence for high concentrations of trapped electrons, apparently sited around the edges of condensed rings. On absorption of oxygen, the concentration of electrons and their delocalization are both decreased, the effect being reversible. A. Harker, A. Marsh and W. F. K. Wynne-Jones (Newcastle) described results on the physical and chemical structure of carbons. Oxygen chemisorption was shown to be markedly affected by hydrogen atoms and metal atoms in the main carbon structure. J. F. Goodman (Cambridge) outlined investigations on the effect of adsorption of oxygen on carbon carried out in Dr. F. P. Bowden's laboratory. They lead to the view that oxygen, by adsorbing between the carbon sheets, lowers the electron density and hence the cohesion between the sheets.

The final section, under the chairmanship of Dr. F. S. Stone, dealt with semiconductors. Dr. Stone's introduction defined *n*- and *p*-type semiconductors, and outlined the results of electron transfer and barrier-layer theory. The saturation coverage of gas is very low (less than 5 per cent) where barrier layers are operative, but in other cases—for example, carbon monoxide and hydrogen on zinc oxide—saturation occurs at high coverages and covalent bonds are probably formed. He described the work of Kubokawa, which has shown how hydrogen may be absorbed on zinc oxide below 110° with no effect on semiconductivity. According to R. Morrison, this may be explained by reaction of hydrogen with chemisorbed O^- species. Ionic processes may also be of importance—for example, in cases such as oxygen on cuprous oxide, calcium oxide and uranium oxide —where surface coverages less than 1 are found.

The next speaker, P. T. Landsberg (Aberdeen), emphasized the experimental criteria necessary for a decision on barrier-layer theory in a specific case. E. R. S. Winter (Birmingham) described the results of oxygen-18 exchange between oxides and various oxygen-containing gases, reviewing earlier work and presenting new data. In many cases the activation energy fell to a lower value at higher temperatures, corresponding to a change-over of the rate-determining step from dissociative adsorption to lattice exchange. Evidence was brought forward to show that the decomposition of nitrous oxide on nickel oxide proceeds on a small fraction of sites and involves the participation of lattice oxygen. Similar results hold for the carbon monoxide–oxygen reaction; but a different set of sites is involved. R. Rudham and F. S. Stone (Bristol) described the chemisorption of oxygen, carbon monoxide and carbon dioxide on cuprous, nickel and cobalt oxides, correlating observed heats with reversibility and surface coverage. Oxygen chemisorption was activated and extensive, exceeding the monolayer in cuprous and cobalt oxides, and this is probably a general effect for oxygen on *p*-type semiconductors. J. D. M. McConnell and L. E. J. Roberts (Harwell) considered adsorption of gases on uranium dioxide and thoria. Oxygen is considered to adsorb on the uranium ion, accepting electrons from the solid, while a carbon monoxide molecule donates electrons to a uranium or thorium ion. There is evidence for an autocatalytic adsorption of oxygen on uranium oxide, analogous to that observed by Dowden and Beebe in 1938 with chromia, and this point raised some discussion. The final paper, by R. J. Davis (Fulham), showed how antiferromagnetic interactions in the cation lattice of α-Cr_2O_3, V_2O_3 and other oxides affect the unit-cell dimensions. He considered that these cation–cation interactions might be involved in the chemisorption of hydrogen, and in ring-closing reactions of hydrocarbons.

The meeting was exceptionally well attended, the discussions were lively on most topics, and the arrangements made by Prof. H. D. Springall and the University College all helped to make the symposium a considerable success. The proceedings of the symposium are to be published in the near future by Butterworths and Co. (Publishers), Ltd.

D. D. Eley

PROGRESS IN RADIOBIOLOGY

CONFERENCE IN STOCKHOLM

The Fifth International Conference on Radiobiology met in Stockholm during August 15–19, under the chairmanship of Prof. George de Hevesy. About 180 scientists from nineteen countries were present, and eighty contributions read and discussed. In comparison with previous meetings, emphasis was placed more on the hæmopoietic and genetic effects of radiation, and less on its primary physical or chemical action.

During the past year, it was shown that hæmopoietic cells injected into heavily irradiated animals of the same, or even of a different, species can colonize the blood-forming tissues of the hosts. This explains how animals can survive lethal doses of radiation if part of their blood-forming tissue is shielded, or if they receive after irradiation an injection of hæmopoietic cells of another animal. The hypothesis that recovery is promoted by some humoral or subcellular factor is now unnecessary, and at this meeting it was reported that the 30-day survival of *CBA* mice after 950 r. depends on the number of intact spleen cells inoculated, and is independent of the number of nuclei of damaged cells (D. W. H. Barnes, M. P. Esnouf and L. A. Stocken). The effectiveness of a given inoculum is greatest when the graft is least different genetically from the host (J. Soska, V. Drasil and Z. Karpfel; J. A. Cohen, O. Vos and D. W. van Bekkum). After 950 r. whole-body irradiation to mice and subsequent injection of spleen cells, the entire blood-forming tissue was taken over by the graft. No reversions to tissue of host origin were observed up to 157 days after grafting from another mouse. With heterologous (rat) grafts, reversion may occur (C. E. Ford, J. L. Hamerton, D. W. H. Barnes and J. F. Loutit).

Of medical interest was a more sensitive assessment of hæmopoietic damage in persons exposed to low occupational doses, by means of a new method of collecting and treating blood-count data (M. Helde). The great sensitivity of red-cell precursors was seen after 50 r. whole-body X-irradiation of rats, when the number of late and intermediate normoblasts in the bone marrow fell to less than 50 per cent in 24 hr. (E. V. Hulse). It now seems established that exposure to radiation increases the risk of leukæmia in man (W. M. Court-Brown). Study of 828 case histories of leukæmia from the Danish cancer register (M. Faber) leads to the conclusion that both chronic myeloid and acute leukæmia can be induced by radiation, and that part of the increased incidence is due to diagnostic X-ray procedures in which bone marrow is exposed. The absorption, retention and removal were described of the decay products of radium and thorium (K. Aurand, W. Jacobi and A. Schraub), of strontium-90 in bone (M. Owen and J. Vaughan) and of yttrium (R. Lewin, B. Rosoff, H. Hart, K. G. Stern and D. Laszlo).

Work done on chemical protectors has failed to reveal a common mechanism for their action. Some earlier observations on cysteamine have not been confirmed (Z. M. Bacq). It was ineffective when given to chicks or administered orally to rats. It was suggested that cysteine and cysteamine act by inducing anoxia (J. F. Duplan and H. Marcovitch; J. A. Cohen, O. Vos and D. W. van Bekkum). Cysteine protected *Glis glis* from mortality if administered twenty-one days after irradiation, provided the animals were kept meanwhile at 4° C. in their hibernating state (H. Kunkel, G. Höhne and H. Maass). It is difficult in this case to see how the protector could interfere with primary radicals or exert its influence by specific reactions involving —SH or —S—S— groups of target molecules (A. Pihl and L. Eldjarn; U. Hagen). We are reminded of the specificity of protectors by the fact that α-thiolamino-acids are protective, whereas β-thiolamino-acids enhance radiation effects in mice (R. Koch). Dose-reduction factors of cysteamine and of β-aminoethyl*iso*thiouronium change with the dose of radiation. Critical damage is thought to occur at different sites after different doses, and the efficiency of protection to vary from site to site (A. Catsch).

Among agents which increase radiosensitivity, oxygen has retained its interest. The sensitivity of *E. coli* irradiated in buffer solution increased with oxygen concentration in the bubbling gas, and reached almost full sensitivity at 3 per cent oxygen (T. Alper). The sensitivity change in Ehrlich ascites tumour cells from anoxia to full oxygenation occurs at lower concentrations of oxygen than previously reported (O. C. A. Scott), and a similar pattern of sensitivity was found in the ascites form of the Yoshida rat sarcoma (W. Dittrich). The sensitivity typical of the anoxic state was attained 3 sec. after stopping the circulation in mouse tails (P. Howard-Flanders). Cooling mice to 0–0·5° C. afforded a dose-reduction factor of 2·8, an effect largely attributed to the anoxic condition of hypothermic animals (S. Hornsey). Organic peroxides produced by X-rays seem to be implicated in mutagenesis in *Drosophila*, since it is potentiated by pretreatment with dihydroxydimethyl peroxide or formaldehyde, or with cyanide or azide (F. H. Sobels).

The question of the contributions of the direct and indirect effects to biological damage received some attention. The direct effect in polythene and dry bovine serum can be influenced by oxygen or temperature, but seems to be independent of small amounts of water (P. Alexander). In contrast, it was claimed that the radiosensitivity of enzymes in wet yeast cells is 2–50 times higher than in dry cells, suggesting a high contribution from the indirect effect (F. Hutchinson).

The respiratory system of mouse-liver slices is affected by doses higher than 10^6 r. Sensitivity is determined by cytochrome *c*, which is destroyed by indirect action (B. Rajewsky, G. Gerber and H. Pauly). Yoshida ascites cells 20 min. after 20,000 r. show a drop in respiration and in aerobic and anaerobic glycolysis, and changing relative levels of adenosine di- and tri-phosphate. These differences become less pronounced at 40 min. (G. Höhne, H. A. Künkel and H. Maass). Incorporation of *dl*-phenylalanine-^{14}C into cell components of mouse liver is higher after 500 r. whole-body exposure (J. A. V. Butler, P. Cohn and A. R. Crathorn). The rate of incorporation of phosphorus-32 into rat thymus deoxyribonucleic acid is reduced to half within 3 min. after 1,000 r. to the whole body (M. G. Ord and L. A. Stocken). Increased incorporation of tracers after irradiation may be due to reduced size of body pool (F. Sherman and A. B. Almeida).

A single sub-sterilizing dose of 1,050 r. given to rabbit ovaries is less damaging to late primordial follicles than if given in fractions of 210 r. every 48 hr. (P. Desaive). The sterilizing dose for female mice, on the other hand, does not seem to be dependent on dose-rate, whether delivered at 2·5 r. daily or in one exposure (H. and U. Langendorff).

In a session on genetic effects in *Drosophila*, H. J. Muller and I. I. Oster presented new evidence that true reversals of the original forked (*f'*) mutation can be induced by X-rays. They believe that point mutations of whatever origin are indistinguishable in principle, and are due to qualitative chemical changes in the gene locus. Alkylating agents were reported to have produced a large number of point mutations in loci that have not been observed to mutate under X-irradiation, and the distribution of chemically and X-ray induced mutations on the *X*-chromosome has been found to vary with the mutagen used (O. G. and M. J. Fahmy). Chromosomes of spermatids are at least twice as sensitive to the X-ray induction of lethals and translocations as those of mature sperm in inseminated females (I. I. Oster). Crossing-over in spermatogonia can be induced by injection of formaldehyde (F. H. Sobels). Chromosome breaks, and possibly also intragenic changes, induced by X-rays in mature sperm, are thought to undergo recovery if the sperm are retained for one day in the male (K. Nordback and C. Auerbach). At least five times as many small-effect detrimental mutations as recessive lethals are induced in male *Drosophila* by X-rays (K. G. Lüning and S. Johnsson). The reduced viability of flies receiving irradiated chromosomes is accompanied by a decreased rate of development, and it was suggested that growth-rate studies might be useful in assessing genetic damage due to radiation in mammals (G. Bonnier).

Two films were shown illustrating the effect on mitotic behaviour of irradiating parts of cells in tissue culture with α-ray microbeams. Sensitivity increased by a factor of 10 from prophase to metaphase (M. I. Davis, I Simon-Reuss and C. L. Smith), and irradiation of chromosomes was much more effective in producing anaphase and telophase abnormalities, than irradiation of cytoplasm only (R. Munro). When roots of *Vicia faba* are irradiated with very high intensities of X-rays, in the range 600–1,200 r./min., a class of chromosome breaks becomes apparent which rejoin very rapidly and which may be due to breakage of ionic bonds. These breaks are to be distinguished from those others, regarded as due to the breakage of co-valent bonds, which remain open for a relatively long time (S. Wolff).

Under the appropriate chairmanship of Prof. Å. Gustaffson, a special session met on the last day to discuss the application of the mutagenic effects of radiation to plant breeding. Facilities and techniques were described for the Brookhaven Laboratory (H. J. Curtis) and plans outlined for the improvement of the rice crop in India (A. R. Gopal-Ayengar). Of 427 radiation-induced mutations in soya beans, only 1 per cent seem to be of some economic value (M. Zacharias). In black currants, selection of mutated shoots from irradiated cuttings was reported to have given promising results (R. Bauer). A review was given of the work of the Swedish group in utilizing 'directed' mutations produced in barley by various physical and chemical agents (D. von Wettstein).

ALMA HOWARD

POPULATION GENETICS

A SYMPOSIUM on population genetics, with particular reference to stability of development, was held on the afternoon of Monday, September 3, at a joint session of Sections D (Zoology) and K (Botany) of the British Association in Sheffield. It was opened with a paper by Dr. J. M. Thoday entitled "Environmental Heterogeneity and the Genetic Architecture of Populations". Dr. Thoday began by pointing out that one of the most remarkable discoveries of recent biology was the great diversity of genotypes to be found in any population of out-breeding species. Comparative uniformity of individual morphology is mediated by a wide range of genotypes, each highly heterozygous and compounded of chromosomes many of which, though successful in heterozygous combinations, are deleterious, or, even lethal, if made homozygous. This great genetic heterogeneity of populations is generally held to find its explanation as an adaptation permitting populations to survive change of their environment. Nevertheless, the heterozygosity on which this individuality depends involves a price, for it necessarily involves the production of some segregants poorly adapted to contemporary environmental conditions and, hence, involves relative infertility. The out-breeding systems by which heterozygosity is maintained are also less secure than self-fertilization. Some scientists therefore find it difficult to believe that the long-term selection for heterozygosity can be powerful enough to over-ride the short-term selection for fertility, and therefore doubt whether it is sufficient as an explanation of the ubiquity of the cross-breeding systems that maintain heterozygosity. Dr. Thoday suggested that if we consider the nature of environment heterogeneity, we find reason to believe that selection for heterozygosity on a relatively short-term basis may be strong. Environmental heterogeneity may be classified as random, directional or cyclic, the latter being the type to which he gave most attention. If the period of the cycle is longer than generation time, then the cycle will involve selection for new genotypes each generation and periodic reversal of the direction of selection. In these circumstances, a population may be expected to become heterozygous for genes appropriate to peak and trough conditions of the environmental cycle. Further, a certain degree of heterozygous advantage is to be expected as a system buffering the population against loss of peak genes in trough conditions, and vice versa. This system is precisely that known to occur in populations of *D. pseudoobscura* studied by Dobzhansky. Superimposed on the system, and hence in a heterozygous context, selection will proceed further to produce *individuals* capable of withstanding a longer and larger proportion of the range of environmental conditions imposed by the cycle. Only the success of this form of evolution can permit the evolution of longer generation times, and the end will be heterozygous individuals that can withstand the whole cycle and hence perhaps live for several cycles.

Dr. Thoday suggested that our finding that the ability of individuals to control their development despite environmental variation very often depends on heterozygosity may well be explicable in terms of such a history of adaptation to cyclic conditions which he attempted to show are ubiquitous, especially since spatial differentiation of the environment must produce cyclic conditions in time, as dispersal of seed, etc., works in both directions.

The remaining papers were all concerned with this ability of individuals to maintain organized 'normal' development despite internally or externally caused disturbances. Mr. J. A. Beardmore reported on the effects of a diurnal temperature cycle on stability as measured by bilateral asymmetry of sternopleural chæta number in *Drosophila melanogaster*. Two long inbred lines the inbreeding history of which had occurred at constant 25° give more stable F_1 hybrids at 25°, the F_2 flies being, if anything, more stable than the F_1. In the fluctuating temperature conditions (mean 25°, midnight 20°, midday 30°), the reverse result is found, the F_1 being less stable than the inbreds and the F_2, if anything, less stable than F_1. He also reported evidence that though laboratory flies from constant-25° rooms are usually less stable in the fluctuating than in the constant-temperature incubator, newly captured wild flies give offspring superior in the fluctuating condition, indicating this to be the nearer to a wild environment. Six months in constant laboratory conditions may be sufficient for populations to lose their relative adaptation to the fluctuating condition. Experiments on natural populations involving comparisons in constant temperatures have therefore to be interpreted with caution.

Mr. J. Maynard Smith followed with a paper entitled "Developmental Flexibility in *Drosophila*". He began by stressing the point that the degree to which the development of organisms is under control or stabilized is not always to be measured by the degree of uniformity of the end product. Sometimes fitness may require different phenotypes in different environments. The superior capacity of outbreds, as compared with inbreds, is usually deemed demonstrated when it is shown that the outbreds are more uniform than corresponding inbreds ; but when the situation is such that optimum phenotype varies with environment, then the best-regulated development should lead to variation of phenotype corresponding to variation of environment, and in these conditions, if outbred individuals are superior to inbreds, they should vary more than inbreds.

Mr. Maynard Smith described his attempt to test this hypothesis in *Drosophila subobscura*. The character measured was the length of time for which adult flies could survive at 33·5° C. in dry air. Three inbred lines and the three hybrid populations between them have been tested. In all three hybrid populations, individuals which were kept at 25° C. as larvæ and pupæ, and then at 15° C. as adults for a week before testing, lived approximately 2·5 times as long as did individuals of the same genotype kept at 15° C. throughout. Thus outbred individuals are capable of long-lasting acclimatization to high temperatures if they are kept at 25° C. during the pre-adult stages. Of the three inbred lines, one showed no capacity for acclimatization, and the other two acclimatized significantly less than did the hybrids. Thus the capacity to withstand exposure to high temperatures is a phenotypic character which can be modified adaptively in response to changed conditions during development, to a greater extent in outbred than in inbred individuals. In this particular case, therefore, the hypothesis outlined above has been confirmed.

The final paper was given by Dr. H. Rees on "The Stability of Meiosis in Inbred and Crossbred Rye". He said that when inbreeding is forced upon a species such as rye, which normally outbreeds, the progeny show inbreeding depression in relation to the chromosome mechanism much as they do for more familiar aspects of the phenotype. At meiosis one general consequence is a reduction in chiasma frequency. In some extreme cases when chromosomes are frequently unpaired and hence lost during cell division, this causes considerable pollen and egg infertility. Another result of inbreeding concerns the stability of plants in relation to chiasma frequencies. Thus *between plants* of identical genotype *within* inbred lines there is more variation in chiasma frequency than between plants of the same genotype within heterozygous families ; under comparable experimental conditions the chiasma frequencies of homozygotes are less stable. Similarly, variation is greater between pollen mother cells within anthers of homozygotes than it is *within anthers* of heterozygotes. It has been found, however, that although homozygotes are generally less stable than heterozygotes, the instability cannot be explained in terms of the degree of homozygosis alone. Inbred lines equally homozygous may show different degrees of instability. Stability evidently must be related to the particular genotype.

Chiasma frequency, of course, to a large extent determines the degree of gene recombination and hence the variability in outbreeding populations. The average chiasma frequency is known to be genotypically controlled. The above results make it clear also that the range of chiasma frequencies within an anther (that is, the degree of 'instability') is also subject to the control of the genotype. From the population point of view this means, therefore, that the average amount of recombination through chiasma formation per plant may be adjusted by natural selection, and that the variety of the gametes, in respect of recombination, can also be adjusted adaptively. J. M. THODAY

THE NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING, SHINFIELD

REPORT FOR 1955

SOME years ago Dr. E. V. McCollum, an eminent American authority on nutrition, stated that "The people who achieved, who have become large, strong, vigorous people, who have reduced their infant mortality, who have the best trades in the world, who have an appreciation for art, literature and music, who are progressive in science and in every activity of the human intellect, are the people who have used liberal amounts of milk and its products" ! Even though this may well be regarded by many as something of an over-statement, it is undoubtedly true that milk contains a greater number of the individual nutrients essential for health in man than any other single food. Calculations made a few years ago showed that home-produced milk, consumed in Great Britain as liquid milk, supplied some 17 per cent of the total protein and some 12 per cent of the total fat in the people's food, as well as important proportions of its minerals, vitamins and energy content. The gross value of the milk and milk products produced annually in Britain amounts at present to some £400 million. Apart from economic considerations, it is worth recalling that the milk secretion process itself is one of the chief physiological functions on which the very existence of mammalian life depends.

With facts like these in mind, it is most encouraging to read of the work that is being done and the progress that is being made at the National Institute for Research in Dairying, Shinfield, under the direction of Prof. H. D. Kay, whose most informative annual report for 1955 has been recently published*. Lists of staff, patrons, fellows and members of the Institute are given, from which it can be seen that the number on the staff of the Institute now exceeds three hundred and that about a hundred of them are graduates in some branch of science.

The report can be regarded as consisting in the main of three principal parts. The first of these is the foreword, which contains a short but valuable outline of some of the recent findings that have been made at the Institute. More than thirty individual items are referred to. This part of the report should be of special interest to those who want to know as briefly as possible, and in an immediately practical way, what advances were made in 1955 without having to read in detail about the work of the Institute as a whole.

The second, and by far the largest, part of the report gives an account of each of the eight principal departments of the Institute, and also discusses the work of the four smaller sections that deal with such a wide variety of subjects as isotopes, statistics, psychology, and liaison with the dairy industry. Some of the problems under investigation are of a very practical nature, such as the prevention of infestation of cheese by mites, and the effect of 'vacuum' level on the rate of milking by machine. Others are scientifically more fundamental and require for their elucidation the expert knowledge and training of research workers in bacteriology, chemistry, physics, physiology, nutrition and engineering. Examples that might be cited of these fundamental researches are the work that is being done on the biochemistry and physiology of milk secretion with particular reference to the formation of fat and protein in the mammary gland, and the detailed study that is being made of the chemistry of the β-lactoglobulins in milk.

A third section of the report, which will prove of special value to many readers, comes under the heading of library. It gives a list, with full titles and references, of the 151 papers that were published by members of the staff between October 1954 and September 1955. A mere glance at this formidable list will impress the reader with the great scope and importance of the researches that are being done by what is clearly a very capable and enthusiastic band of workers.

THE BRITISH STEEL CASTINGS RESEARCH ASSOCIATION

ANNUAL REPORT

THE British Steel Castings Research Association is one of the newest of the research associations operating under the aegis of the Department of Scientific and Industrial Research; although now having produced its third annual report*, this co-operative research organization, before it became attached to the Department, had been operating for some years under the wing of the British Steel Founders' Association. These were formative years, but from the present report it is apparent that this young and virile research body has reached a promising stage of development; and a new research station is in course of erection at a suitable site in Sheffield, the home of so many famous developments in the steel world.

The steel-founding industry in Britain would appear from this report to be a compact and co-operative industry, well able to uphold the best traditions of British engineering industry. Much of the work of the Association in its brief existence has been confined to work carried out in member foundries. This liaison would appear to be particularly good, advisory work being also done by the Association's staff. Further, extramural research has been supported at several universities, and work of considerable value has emerged from these activities.

In the early days of its existence, the parent body of the Association, known as the Research and Development Division of the British Steel Founders' Association, took over from the British Iron and Steel Research Association the work of the old Steel Castings Committee, which had been responsible for notable activities in the field of steel founding, in particular in regard to steel casting, moulding sand and furnace refractory practice. From the days of Boswell in the First World War, when the first scientific studies of British moulding sands were undertaken in a number of foundries, the steel-founding industry has applied progressively scientific methods to its moulding practice; the developments outlined represent, on the part of the steel-founding industry, the realization of the value of co-operative scientific research. The work in the past has been closely associated with the Refractories Department of the University of Sheffield. From my own experience of the industry, this aspect of the work has already gained world-wide recognition, both in regard to the properties of the moulding materials available in Britain, and the bearing which founding techniques may have on the quality of the casting. The aim of the founder is to make a sound casting with the minimum of sand adherence, not only for the purpose of economical production in the foundry, but also with the object of reducing the health hazard in the foundry and the fettling shop.

---

* British Steel Castings Research Association. Third Annual Report, 1956. Pp. ii+25. (The Association, Broomgrove Lodge, Sheffield 10.)

The work of the Association is under the direction of Dr. A. H. Sully, and is divided into five main sections: (i) metallurgy, comprising in itself a field of wide scope, for man's mastery of the properties of metals is a never-ending pursuit; (ii) foundry practice and moulding materials; (iii) steelmaking; (iv) plant engineering; and (v) industrial health.

In the metallurgical field the immediate problems have been to study the practical techniques that produce sound castings and thereby the optimum mechanical properties, which the ever-increasing demands of engineering practice may require. This has involved the study of the interdendritic microporosity in steel castings, which may be of more widespread occurrence than is generally appreciated. An increasing need in engineering practice has been for materials that remain tough at very low temperatures. An investigation into such properties referred to in the present report has shown that for low- and medium-alloy steels the highest resistance at low temperatures is developed in fully hardened and tempered steels. The importance has also been demonstrated of avoiding temper brittleness in steels known to be susceptible to it by water quenching from the tempering temperature.

Considerable light has been thrown on the problem of sand adherence to steel castings by investigations carried out under Dr. T. P. Hoar at the University of Cambridge under the sponsorship of the Association. Equally interesting in these respects has been the research carried out under the supervision of Prof. J. White at the University of Sheffield on the hot-strength properties of moulding sands. Reaching the scale of extended and promising trials on the foundry floor is the use of sands bonded with bentonite–kaolinite clay mixtures that have been shown in the laboratory to have better foundry 'life' properties than mixes bonded solely with bentonites, the latter being generally an imported raw material.

In the steelmaking investigations, particular attention is being devoted to the use of oxygen injection, a relatively modern practice which promises to give enhanced control to the steelmaking process. Efforts are also being made to bring the conclusions of the many erudite studies of the physical chemistry of steelmaking on to the stage of the steel-melting furnace.

Plant engineering must ever be important in the growing mechanization and instrumentation in all types of industrial practice. In an industry in which the art of founding is applied, a complexity of process is inevitable, and therefore the engineering aspects introduce a wealth of needs. Improvements in fettling tools and moulding machines accordingly introduce problems that are to be found in the research programme.

Notable advances have been made in the field of industrial health. The Association has succeeded in introducing new methods of dust control in stand and swing-frame grinders, that have received the approval of H.M. Factory Inspectorate. One of the outstandingly successful events of the Association's year was the conference on "Steel Foundry Dust Control and Ventilation" held at York in October. The report of this conference has been adjudged by the practical observers of developments in the industry to have constituted a milestone of progress against the health hazards of the steel foundry, an achievement that must have valuable economic and social results.

The Association has a Technical Advisory Committee structure that is not too unwieldy, and yet brings to the Committee table the best brains in the industry, a commendable situation in these days when the efforts of too many executives and technical men tend to become strained in an almost committee-ridden age. In regard to the Library and Information Services, the policy has been continued of building up as complete a collection as possible of current literature on steel-foundry subjects, while relying on borrowing and interchange to fulfil marginal needs and other requirements. In these respects, Sheffield is building up an enviable reputation for the efficiency of its library and interchange services, so important a need in a great technological centre. The *Abstract Journal* of this Association can be regarded as one of the best of its kind. The new Research Station is expected to be completed before the end of the year.

R. J. Sarjant

COMPARISON OF SOME DIRECT AND INDIRECT EFFECTS OF IONIZING RADIATIONS IN PROTEIN

By Dr. P. ALEXANDER, Dr. M. FOX*, Dr. K. A. STACEY and D. ROSEN

Chester Beatty Research Institute and Physics Department, Institute of Cancer Research, London, S.W.3

A NUMBER of investigations[1] have shown that changes in chemical and physical properties of proteins occur after irradiation both in dilute aqueous solution, when the action is produced by the free radicals formed in the water, and in the solid state, when the energy is absorbed directly by the protein. We have studied with the same proteins both types of process to illustrate their similarities and differences. The relative efficiency of the two processes may provide a guide to their relative importance in initiating the series of processes which lead to cellular damage. The principal criteria used for determining alterations in the protein have been changes in solubility, ultra-violet absorption, chromatographic behaviour and alterations in molecular weight as revealed by light-scattering and the ultracentrifuge.

---

* Present address: Fisons, Ltd., Felixstowe.

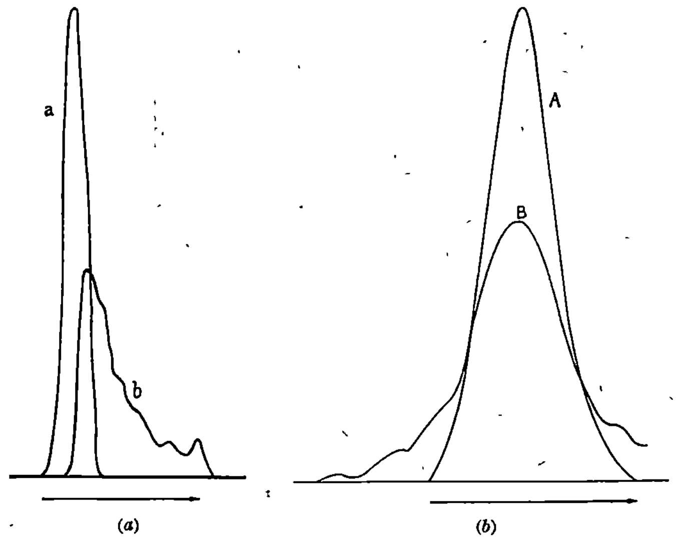

Fig. 1. The Lamm scale ultracentrifuge diagrams of irradiated bovine serum albumin.

(a) Indirect effect. The control solution (a), and the irradiated solution (b) which has received 100,000 r., are 1 per cent.

(b) Direct effect. The solid has received 8 × 10^6 r. and is measured as a 1 per cent solution (B) compared with a control solution (A)

Indirect Effect

Dilute solutions of proteins are precipitated by irradiation with a sufficiently high dose ; but little is known about the changes which precede this effect. Several workers[2,3] have reported on the apparent increase in the ultra-violet absorption and the formation of dimers upon the X-irradiation of serum albumin and fibrinogen, whereas hæmocyanin was shown by Svedberg and Brohult[4] to split into well-defined sub-units by α-irradiation.

We have found a marked rise in the weight average molecular weight of serum albumin (both human and bovine) as determined by light scattering upon exposure of dilute solutions to X-irradiation. This rise is due to the formation of a very polydisperse range of aggregates which have been shown by examination in the ultracentrifuge[5] (Fig. 1a) and the electron microscope to range from dimers up to units of many hundred molecules. Since the apparent molecular weight as measured by light scattering depended on the ionic strength of the solution in which the measurement was made, and furthermore could be reduced by the addition of urea (final strength 4 M) the larger aggregates behave as associations of partially denatured molecules held together by secondary forces. The proportion of protein in the main ultracentrifuge peak was unaltered by the addition of urea, so that it is probable that the smaller aggregates are covalently cross-linked.

We have confirmed the observation that the ultra-violet absorption of serum albumin at 280 mμ apparently increases after irradiation, but cannot accept the contention that this is the result of a preferential attack on the tyrosine residues which are responsible for this band[3]. The apparent increase is due to loss of light by the greatly increased scattering by the large aggregates formed on irradiation. The light scattering was measured directly at 436 and 546 mμ with an instrument used for molecular weight determinations, and the scattering at other wave-lengths was calculated by the Rayleigh–Debye equation. These values were used for correcting the spectrum determined in a spectrophotometer, when it is seen (Fig. 2) that the true absorption of the protein is only slightly, if at all, changed on irradiation. The correction applied for scattering may be somewhat too small, since the scattering was only determined for the angles between 40° to 135°, which will give a low value of the total loss of light due to the largest aggregates. For the experiment shown in Fig. 2, the weight-average molecular weight increased from 7 × 10^4 to 1·5 × 10^6, while the number-average, estimated from the decrease in the amount of material with the sedimentation constant of the starting material, cannot have exceeded 1·5 × 10^5. The great difference between these two averages proves that some very large aggregates must be present. If the serum albumin was irradiated in the presence of salt or titrated to a pH away from its isoelectric point, the change in the ultra-violet spectrum was less. This effect is not the result of protection by competition for the radicals formed by the salt, but is due to the fact that the aggregates formed are smaller and therefore scatter less light.

While the absorption of serum albumin at 280 mμ is almost wholly due to tyrosine, that of lysozyme at the same wave-length is due to tryptophan. On irradiation of dilute solutions of this enzyme with X-rays (see Fig. 3) the ultra-violet maximum first decreases, but increases again with larger doses. The initial effect probably represents a preferential attack on the tryptophan by the free radicals formed by irradiating water. This behaviour may be correlated with the ability of tryptophan and its derivatives to compete very effectively with other substances for free radicals produced in solution[9]. The increase at higher doses is again due to aggregation, and on correcting for this by measuring the scattered light, it appeared that the true absorption maximum continues to decrease.

The object of further research will be to determine the primary chemical changes, produced by the radiation, which result in the observed aggregation. This aggregation reflects a most significant physico-

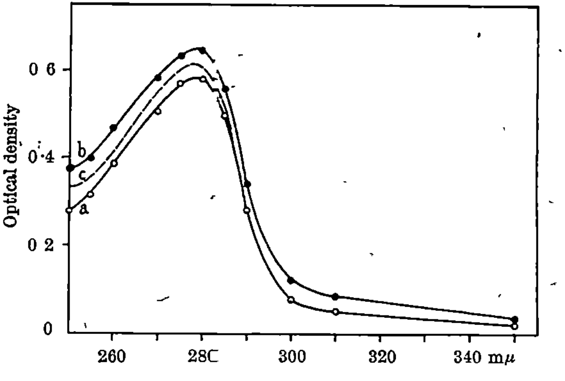

Fig. 2. Effect of irradiation on the ultra-violet spectrum of bovine serum albumin ; 30,000 r. was delivered to a 0·1 per cent solution. The light scattering at 437 mμ and ultra-violet absorption was determined at 0·044 per cent in 0·1 M sodium chloride. The correction due solely to light scattering was calculated from the molecular weight, 1 5 × 10^6 and the dissymmetry [∼ 2]. (a) Control ; (b) irradiated protein ; (c) corrected curve

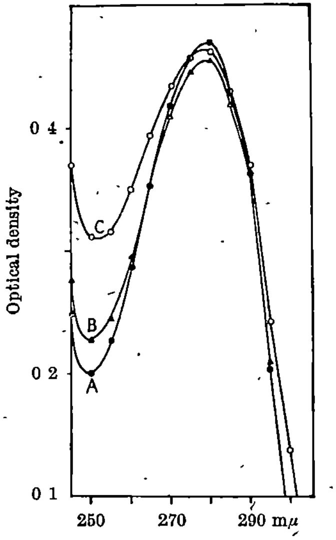

Fig. 3. Ultra-violet absorption spectrum of 0·025 per cent solutions of lysozyme (*B*) after 10,000 r., and (*C*) after 30,000 r., compared with an unirradiated control (*A*)

chemical change following an indirect action, and may also give rise to the other changes reported, such as more facile heat denaturation.

Direct Action

The irradiation of solid serum albumin produces effects which are quite different from those following indirect action. The protein was not dried completely, since it was felt that the presence of approximately 5 per cent of water, which is essential to retain the protein in its native form, would not introduce any significant 'indirect' contribution.

The radiation effect is influenced by the presence of oxygen; irradiation with γ-rays in air begins to render part of the sample insoluble in water at 4 × 10^6 r., and at 8 × 10^6 r. 90 per cent failed to pass through a filter of pore size less than 0·3μ after suspending in water. The fraction dissolving contains large aggregates, and these appear to behave in a similar way to those produced by indirect action; for example, a sample of bovine serum albumin given a dose of 2 × 10^6 r. has a weight-average molecular weight of 1·5 × 10^6. The ultracentrifuge pattern (Fig. 1*b*) again shows that the irradiated protein is polydisperse and contains material of very high molecular weight. But unlike the protein irradiated in solution, some of this material sediments more slowly than the starting product, indicating that some degradation has taken place. The aggregate can, in part, be dispersed by concentrated urea. This will also dissolve some of the protein which had become insoluble in water with doses greater than 6 × 10^6 r. This behaviour suggests that secondary forces contribute to aggregation; but that new covalent inter-molecular cross-links are formed.

Irradiation of the dry material brings about a true change in ultra-violet absorption, as can be seen from Fig. 4, where the absorption measured has been corrected for scattering by the aggregates. This indicates that the tyrosine is attacked; the extent of the change is much greater than could be accounted for by energy taken up directly in the tyrosine residues themselves. The ultra-violet spectrum of polytyrosine (a sample kindly given by Dr. E. Katchalsky) is not detectably altered by the dose which produces a 20 per cent change in serum albumin. Since the initial uptake of energy is independent of the molecular structure, the same *fraction* of the tyrosine should be affected in a protein as in a polypeptide entirely composed of tyrosine residues. The observation that a greater proportion of the tyrosine is affected in the protein suggests that energy taken up in other amino-acid residues contributes to the attack on the tyrosine. This appears to be another example of a process found in other systems[7] also which we have referred to as energy transfer without implying any particular physical or chemical mechanism.

When a 1 per cent aqueous solution of serum albumin was irradiated with α-particles from polonium, the changes produced resembled those from the direct action of γ-rays, in that the ultra-violet absorption was generally increased and both aggregation and degradation were found. Since the biological effectiveness of α-rays is considerably greater than that of X-rays, we believe that the similarity of the effect of α-rays to direct action by sparsely ionizing radiation may be biologically significant.

Oxygen Effect

Barron and his colleagues[3] showed that the physico-chemical change produced by irradiation of serum albumin in solution was influenced by oxygen; but we were surprised when substantial differences were found between irradiations of the solid carried out in oxygen and in vacuum, since it was generally believed that oxygen effects occurred only when the action of the radiation was indirect. The first effect of irradiation is to produce aggregates, and with bigger doses true insolubility in water sets in. Both effects occur much more readily following irradiation in the presence of oxygen, and, for example, 8 × 10^6 r. in air renders 50 per cent insoluble while the same dose

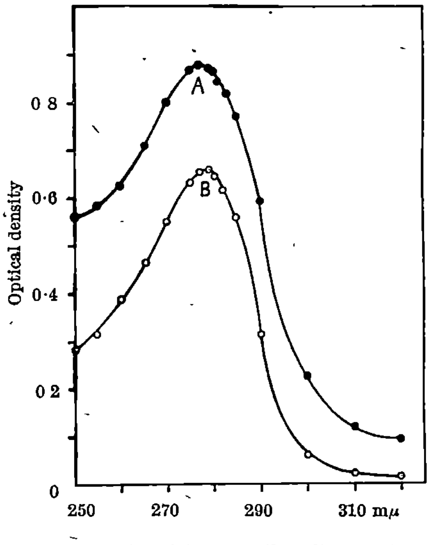

Fig. 4. Effect of irradiation on the ultra-violet absorption spectrum of solid serum albumin. The spectrum of a 0·1 per cent solution of material which has received 8 × 10^6 r. (in air) (*A*) is compared with that of an unirradiated control (*B*). The insoluble fraction (about 50 per cent) has been removed by a porous porcelain filter candle (max. pore diameter 0·5μ). Light-scattering measurements show that none of this increase is due to aggregation, since the weight-average molecular weight is less than 200,000

given *in vacuo* only produces aggregation which can be detected by light scattering and ultrafiltration.

Preliminary experiments showed that irradiation in oxygen introduces into serum albumin new groups (possibly unstable peroxides) which are capable of initiating the polymerization of vinyl compounds. For example, the addition of 20 mgm. of protein given 2×10^6 r. to 10 ml. of a 10 per cent aqueous solution of methacrylic acid, followed by removal of air from the solution, initiated immediate polymerization and the product appeared to be a 'graft' macromolecule containing protein and polymethacrylic acid. Unirradiated or vacuum-irradiated protein was ineffective for this purpose.

From ultracentrifuge measurements the amount of serum albumin having the sedimentation constant of the original material was determined after different irradiations. For indirect irradiation the rate of disappearance decreases with dose; but from the initial slope it can be computed[5] that one protein molecule becomes incorporated in an aggregate for every 250 eV. of energy deposited in the system (hence $G = 0{\cdot}4$). When the solid protein was irradiated, one molecule disappeared from the original peak in the ultracentrifuge pattern for every 50 eV. of energy taken up. Hence $G = 2{\cdot}0$ if oxygen is present, but the value is much less *in vacuo*. For this aggregation process direct action is approximately five times as efficient as indirect processes, and this shows, as has already been pointed out for the degradation of deoxyribonucleic acid[8], that the great preponderance of water in most living systems does not necessarily imply that the contribution of indirect action predominates in initiating the chain of events leading to the final injuries.

The ultracentrifuge measurements were made in the Institute for Physical Chemistry, Upsala, Sweden, and will be published jointly with Dr. Sven Brohult.

This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

GENETICS OF HÆMOGLOBIN AND BLOOD POTASSIUM DIFFERENCES IN SHEEP

By J. V. EVANS
Rowett Research Institute, Bucksburn, Aberdeenshire

J. W. B. KING
Agricultural Research Council Animal Breeding Research Organization, Edinburgh

AND

B. L. COHEN, H. HARRIS and PROF. F. L. WARREN
Department of Biochemistry, London Hospital Medical College, London, E.1

If hæmoglobin preparations from different adult sheep are subjected to electrophoresis on filter paper at *p*H 8·6, three distinct types of animal may be recognized[1]. One finds either a single component moving relatively rapidly towards the anode, or a single component moving rather more slowly, or a mixture apparently consisting of both these components. We will refer to the hæmoglobin moving more rapidly towards the anode at *p*H 8·6 as sheep hæmoglobin *A*, and to the less rapidly migrating hæmoglobin as sheep hæmoglobin *B*. The three types of animal can then be conveniently designated as *A*, *B* or *AB* with respect to their hæmoglobin constitution (Fig. 1).

Sheep may also be classified into two distinct types according to the potassium and sodium concentrations in their blood[2]. In one type the potassium concentration is relatively high (about 36 m.equiv./l.) and the sodium concentration correspondingly low, whereas in the other type the potassium concentration is relatively low (about 11 m.equiv./l.) and the sodium concentration correspondingly high. The two types of animal have been called *HK* and *LK*, respectively. The plasma potassium concentrations are the same in the two types of animal and the phenomenon is therefore entirely due to differences in the red blood cells. Preliminary evidence has indicated that these two types are genetically determined in a simple Mendelian manner, the *HK* type being recessive[3].

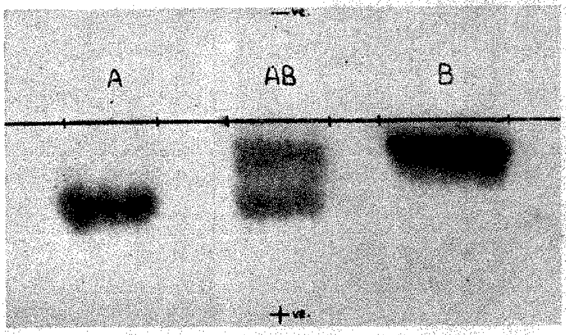

Fig. 1. Paper electrophoresis of the three types of sheep hæmoglobin
(0·15 *M* borate buffer, *p*H 8·6, 185 V., 17 hr.)

In the present investigation, the hæmoglobin and potassium types were determined on a large number of individual animals from a single flock in which detailed pedigrees were available. It was hoped to study among other things the genetics of the overall situation and to investigate any interrelationship between the two sets of red blood-cell characteristics.

A flock of Lanark-type Scottish Blackface sheep on rough hill grazing in Peebleshire was examined. The animals were bled at weaning time when the lambs were approximately six months old and the ewes varied from 2½ to 5½ years of age.

Table 1. Hæmoglobin and Potassium Types in 1,804 Scottish Blackface Sheep

	Hæmoglobin type *A*	*AB*	*B*	Totals
High-potassium	577	314	46	937
Low-potassium	521	282	64	867
Totals	1,098	596	110	1,804

Table 1 shows the frequencies of the different phenotypes in 1,804 animals in which complete data were obtained. 61 per cent of the animals were of hæmoglobin type *A*, 33 per cent *AB*, and 6 per cent *B*. 52 per cent of the animals were *HK* and 48 per cent *LK*. There was no obvious association between any of the hæmoglobin types and either of the potassium types, and the two systems of classification appear to be independent.

Table 2 summarizes the family data in the hæmoglobin types. The table is incomplete with regard to certain of the mating types, because many of the rams used for producing the lamb crop had been sold before the hæmoglobin determinations were made. Nevertheless, a typical segregation pattern may be observed. *A* offspring are not produced if one or other parent is *B*, and *B* offspring are not produced if one or other parent is *A*. *A* × *A* matings produce only *A* offspring, whereas *AB* × *AB* matings produce all three types. The findings are consistent with the hypothesis that the hæmoglobin types are genetically determined by two alleles each responsible for the formation of one kind of hæmoglobin. On this hypothesis the gene frequencies can be obtained directly by counting, and in this population the frequency for the *A* hæmoglobin would be about 0·77 and that for the *B* hæmoglobin 0·23. Assuming random mating and no differential selection, one can calculate from the Hardy–Weinberg equation the expected proportion of the three phenotypes in the total population. Fairly good agreement is in fact obtained (Table 3). However, there is a slight deficiency of heterozygotes, the explanation of which is uncertain.

Table 2. Segregation of Hæmoglobin Types

Parents		Offspring			
Ram	Ewe	*A*	*AB*	*B*	Total
A	× *A*	32	—	—	32
A	× *AB*	11	2	—	13
A	× *B*	—	1	—	1
AB	× *A*	25	23	—	48
AB	× *AB*	8	12	8	28
AB	× *B*	—	1	4	5
?	× *A*	200	64	—	264
?	× *AB*	61	66	14	141
?	× *B*	—	17	9	26
		337	186	35	558

Table 3. Hæmoglobin Types in 1,933 Animals. A Comparison of the Observed and Expected Proportions assuming a Hardy–Weinberg Equil'brium

Hæmoglobin type	Observed No.	Observed Per cent	Expected No.	Expected Per cent
A	1,173	60·7	1,155	59·8
AB	642	33·2	678	35·1
B	118	6·1	100	5·2
Totals	1,933		1,933	

Table 4. Segregation of Potassium Types

Parents		Offspring			
		Observed		Expected	
Ram	Ewe	*HK*	*LK*	*HK*	*LK*
HK	× *HK*	106	2	105	—
HK	× *LK*	35	63	42	59
LK	× *HK*	39	39	35	46
LK	× *LK*	17	64	14	64
		197	168	196	169

Table 4 summarizes the data on the inheritance of the *HK* and *LK* types. The expected numbers of segregants from the different matings have been calculated on the hypothesis that the dimorphism is due to a single gene pair, that *HK* is recessive and that mating is at random. The observed and expected numbers are in good agreement. The only notable discrepancy is the occurrence of two *LK* animals from matings of *HK* parents, and these can probably be attributed to mistaken identity or illegitimacy. The *HK* animals can therefore be regarded as homozygous for one allele whereas the *LK* animals represent the heterozygotes and also the homozygotes for the other allele. The possibility that the gene responsible for the *LK* phenotype may not be completely dominant has been examined by comparing the quantitative findings in known heterozygotes with those obtained in the remainder of the *LK* animals. A significant difference of 0·68 m.equiv./l. whole blood was observed, the heterozygote having the higher value. This would imply an average difference between heterozygous and homozygous *LK* animals of about 1·7 m.equiv./l.

The absence of association between the hæmoglobin phenotypes and the potassium phenotypes presumably means that the genes responsible for the two sets of red cell characteristics are at independent loci. Nevertheless, in both high- and low-potassium phenotypes, individuals with hæmoglobin *A* have higher average values of whole-blood potassium than those with hæmoglobin *B*, whereas the *AB* individuals are intermediate.

Table 5. Mean Concentrations of Whole-blood Potassium in each Phenotype

Hæmoglobin type	Potassium type *HK*	*LK*
A	38·8 ± 0·2	12·0 ± 0·1
AB	36·4 ± 0·2	11·3 ± 0·1
B	34·8 ± 0·6	10·6 ± 0·2

Data on the concentration of red blood-cell potassium in the different hæmoglobin types will obviously be required before the physiological significance of this correlation can be assessed.

One of us (F. L. W.) is in receipt of a grant from the Agricultural Research Council.

NATURE OF THE TUMOUR-ENHANCING FACTOR

By Prof. H. N. GREEN and R. WILSON

Department of Experimental Pathology and Cancer Research, School of Medicine, Thoresby Place, Leeds 2

INTEREST in the nature and mechanism of the enhancing factors present in tumour and normal tissues has increased latterly, though first described by Flexner and Jobling[1] so long ago as 1907. We have recently reviewed[2], *inter alia*, the literature of the enhancing factors which break down homologous and even heterologous host resistance to transplanted tumours and have worked with them for several years, realizing that they provide an important clue to the nature of certain tissue antigens concerned both in tumour immunology and in transplantation surgery.

The rat sarcoma (*Rd*/3) used was responsive to the enhancing factor in lyophilized *Rd*/3 sarcoma[3]; and from experiments using cortisone in normal and adrenalectomized rats, it was suggested that the enhancing factor effect was the indirect result of a heightened immunity, which was of a different order to immunity to living tumour cells for it occasioned no plasma cell response, nor increase in size of the lymph nodes or spleen. The work of Kaliss[4] showing that combined pre-treatment with cortisone and enhancing factor weakened or abolished the enhancing effect was confirmed in rats[5], as was that of Kaliss and Molomut[6], who showed that enhancing factor activity was present in rabbit and mice antisera to mixed mouse tissue antigens.

All results, including the appearance of rat-cell hæmolysins in the serum, pointed to the apparent paradox that enhancing factor treatment was a process of active immunization. Since tumour immunity was abolished thereby, lethal tumour antibodies were not being induced, and a working hypothesis was the formation of an incomplete or blocking antibody. This accorded with the fact that enhancing factor activity was not found in extracts of completely normal tissues, but only in those damaged by heating, freezing, mechanical disintegration, etc. (see Green[2]). A search was begun for the responsible tumour antigen(s) and by that time much serological work on tumour-bearing animals suggested that tumour lipids and lipoproteins might be incriminated, particularly as it was already known that enhancing factor activity was present both in fatty and watery tissue extracts. Work was in progress (Hakim and Green[7]) suggesting, *inter alia*, that the spontaneous tumour after transplantation might contain new phospholipids. (The work is still incomplete, but Hakim[8] has published a short account of some of it.) A phospholipid extract from *Rd*/3 sarcoma was thus available and it was injected into a strain of Wistar rats (Leeds) which at that time was resistant to growth of this tumour. In the first experiment thirty-four of thirty-six treated rats grew lethal tumours and only one of ten controls. A second experiment was nearly as decisive. The lipid was effective in doses of 4–0·4 mgm. when mixed with the tumour inoculum or given intraperitoneally. As it transpired, these were lucky results, such small doses being effective, probably because only very slight lowering of immunity was needed to break down strain resistance. In succeeding experiments the tumour was rapidly adapting itself to the host. This factor was not then realized, and failure to obtain enhancement with later lipid fractions led us to numerous modifications in extraction methods without success, for neither tumour phospholipid nor lipoprotein was regularly enhancing in pre-treated rats, but more often immunizing. Employing much higher doses, however, the last three experiments were even more decisive than the first, and it is now certain that the enhancing factor activity resides mainly, if not wholly, in the tumour lipoproteins and that the phospholipids, when artificially separated, retain much of this activity.

Table 1. ENHANCING EFFECT OF FRACTIONS FROM FROZEN *Rd*/3 SARCOMA

Average figures of groups of five rats injected during ten days prior to tumour transplant

Tumour preparation	Dose	Tumour area 13 days (sq. cm.)	Tumour wt./100 gm. carcass 16 days (gm.)	Spleen wt./100 gm. carcass 16 days (mgm.)
Saline emulsion of frozen tumour	0·5 ml.	2·1	19·9	287
50 per cent soluble protein	3 × 1 ml.	2·0	19·3	377
50 per cent soluble protein (petrol. ether extracted)	3 × 1 ml.	1·9	21·4	310
Lipoprotein*	3 × 10 mgm.	2·2	20·6	363
Crude phospholipid*	3 × 25 mgm.	1·9	20·2	413
Nil	—	1·2	8·6	721

All given intraperitoneally except Group 1 which was subcutaneous.

* Enhancement now maintained for 4 generations without further treatment.

Table 2. ENHANCING EFFECT OF FRACTIONS FROM FRESH *Rd*/3 SARCOMA

Average figures of groups of seven rats injected over ten days prior to tumour transplant

Tumour preparation	Dose	Route	Tumour wt./100 gm. carcass at 14 days (gm.)	Spleen wt./100 gm. carcass at 14 days (mgm.)
50 per cent soluble protein	5 × 1 ml.	Intraperitoneal	17·6	466
50 per cent soluble protein (petrol ether extracted)	5 × 1 ml.	,,	16·7	425
Soluble protein (lipoprotein extracted)	5 × 1 ml.	,,	9·4	590
Lipoprotein*	2 × 17 mgm.	Intravenous	19·8	401
Phospholipid*	2 × 50 mgm.	,,	16·5	408
Controls	—	—	8·1	680

* Enhancement now maintained for 4 generations without further treatment.

The results of two experiments are given in Tables 1 and 2. In one the tumour was stored at 0° C. for fourteen days, whereas in the other fresh tissue was used. The extracts were prepared as follows:

Soluble protein: Sarcoma homogenized in blender in normal saline to yield a 50 per cent (wet weight) solution. Stood 30 min. (0–5° C.), centrifuged at 4,000 rev./min. for 2 hr. Supernatant solution used.

Lipoprotein: Cold ethanol added slowly with stirring to equal volume soluble protein extract. Stood 12 hr. (0–5° C.), centrifuged and supernatant dialysed 24 hr. against 0·1 *M* saline using 'Visking' dialysis tubing. Lipoprotein freeze-dried.

Soluble protein after lipoprotein extraction: Alcohol precipitate redissolved in normal saline to yield 50 per cent (equiv.) solution.

Crude phospholipid: Sarcoma homogenized with 10 vol. cold 95 per cent ethanol–ether (3 : 1) for 15 min. Stood 30 min. Centrifuged to clarify. Supernatant concentrated to a few millilitres by vacuum distillation under nitrogen at room temperature. Residue extracted with three volumes of chloroform repeated thrice. Chloroform extract washed overnight in cold room with distilled water, and vacuum-distilled under nitrogen at room temperature.

Refined phospholipid: Crude phospholipid dissolved in petroleum ether (40–60° C.), centrifuged and any sediment discarded, precipitated with excess of acetone and a few drops of a cold saturated solution of magnesium chloride in ethanol.

The results were unequivocal and show that in both frozen or fresh tumour homogenate the enhancing factor is associated with a tumour lipoprotein fraction, little activity remaining after its removal, whereas the lipid-extracted soluble proteins retained full activity. Enhancing activity was greater in material from frozen tumours, and it should be noted that a simple unhomogenized suspension of frozen tumour was rich in enhancing factor. Tumour phospholipids were also active though not quite so much as the lipoprotein. In one experiment (Table 2) additional groups (not tabulated) were given serum and serum gamma-globulin from sarcoma-bearing and normal rats, and splenic soluble proteins from tumour-bearing rats. In all groups there was slight but definite enhancement, the greatest being with gamma-globulin from tumour-bearing rats, thus confirming the result of Kaliss and Kandutsch[9] in mice.

A striking feature was the size of the spleen, which normally progressively increases during growth of this tumour. There was an inverse relationship between splenic size and the enhancing activity of the extracts (cf. Tables 1 and 2) which has been evident in all successful experiments. Enhancement abolishes the normal immune reaction of the host to the tumour.

From these results and many others, the chemical nature of enhancing factor is now clear and its mode of action fairly clear. It is a lipoprotein, and the lipid haptene, which is also enhancing, is a phospholipid(s). The former is the water-soluble enhancing factor and the latter the fat-solvent-soluble enhancing factor. The chemical nature of the active phospholipid(s) is still not certain, though work in progress with Mr. J. W. Westrop should soon be conclusive for at least one tumour. The indications are that it may vary with type of tumour and with the species.

It seems that on injection it is capable of binding with protein and becoming antigenic lipoprotein. From the results of diverse immunization methods, it is clear that both tumour lipoprotein and phospholipid are antigenic in the rat, mouse and rabbit and elicit lipoprotein antibodies. Such serum antibodies have themselves some enhancing action, so that the enhancing factor effect cannot be due to fixation of tumour antibody by the excess antigen injected.

How do such antibodies in sufficient quantity abolish the normal immune response to the tumour? One of us (H. N. G.) has adopted throughout this work the hypothesis that they are blocking antibodies which render the tumour antigens inert. Our results support this; but Billingham *et al.*[10] have suggested that nucleoprotein antigens are destroyed by a mild injury which leaves the cytoplasmic antigens intact, and that antibodies to the latter inactivate the nuclear antigens emerging from the graft. Our findings also accord with this hypothesis, for the lipoproteins do elicit serum antibodies, including hæmagglutinins. Our hypothesis differs in envisaging neutralization of lipoprotein antigens in the cell membrane with possibly, though not necessarily, blocking of normal antibody. This does not easily account for the restoration of immunity in the animal treated with enhancing factor by grafting of immune lymph nodes and the fact, which we have repeatedly observed, that no enhancement is possible in the actively immunized rat (that is, after regression of a tumour). In the first case, however, normal antibody may be at such a high level when the tumour inoculum is given that it over-rides any blocking effect of incomplete antibody. In the second case, it is also likely that the injection of a slightly modified antigen would stimulate the production, already in progress, of normal antibodies. However, the fact that serum gamma-globulin from tumour-bearing rats has some enhancing action suggests that normal lipoprotein antibody is involved. The facts best fit the hypothesis of Billingham *et al.*[10], though it must be emphasized that the lipoprotein antigens are also very unstable and that antibodies to them might not unite with a pure nucleoprotein—a lipo-nucleoprotein complex in the nucleus might, however, be envisaged.

The importance of the present results, however, is their bearing on the homologous grafting of normal tissues. The facts undoubtedly apply here in some degree, for the iso-antigen(s) of tumour cells differs only quantitatively from the normal. The results of many attempts to produce tolerance to skin and other tissue grafts with normal phospholipids and lipoproteins have been erratic; but recent results are encouraging. The ultimate possibility of producing tolerance to normal tissue homografts, and even heterografts, by pre-treatment with specific lipoproteins will, when realized, profoundly affect the scope of surgery. The experiments reported here and related ones, together with their bearing on the immunological theory[2,12] of cancer, will be presented in detail later.

DIURNAL RHYTHMS IN SEMEN YIELDS AND MATING BEHAVIOUR IN THE DOMESTIC COCK

By P. E. LAKE and D. G. M. WOOD-GUSH

Agricultural Research Council Poultry Research Centre, West Mains Road, Edinburgh

WELLS[1] has suggested that much avian behaviour may be based on inherent rhythms. The mating activity of the domestic cock shows a marked diurnal rhythm[2-4], in that the majority of matings occur in the late afternoon. Riley[5] and Macartney[6] found that mitotic activity in the cock's testis was greatest during the night, thus suggesting that the production of spermatozoa may not be uniform during the day. The object of this work is to investigate the relationship between semen yields and mating activity in the Brown Leghorn cock.

Twelve cocks selected on their ability to produce adequate semen samples were used as semen donors. They were kept in individual cages where they had access to mash and water at all times, and in the late afternoon they were given grain. They were divided into three groups of four, and semen was collected on three days—May 30, June 4 and June 9 —during the periods 08.30–09.30, 12.00–13.00 and 17.00–18.00 hr. Each group was tested at a different time on subsequent days of collection. This procedure was followed as it was considered, from previous experience, that over the short period of the experiment there would be no systematic changes in semen yields. Semen was collected by lumbar massage three times during the hours stipulated above, and the total volume and total absolute number of spermatozoa yielded were assessed for each cock.

To estimate the number of spermatozoa, a Spekker photo-electric fluorimeter was used as a turbidimeter, with a 1 in 500 dilution of semen and neutral filters (*H*508). The instrument had been calibrated previously against counts of spermatozoa made with a haemocytometer. The diluting fluid was a 1·025 per cent solution of sodium chloride containing 1 per cent formalin.

Two cocks of the same age and breed as the donors were used for observations on mating frequencies. They were each resident in a pen with laying hens and were each observed on two days between May 30 and June 10 during the hours of semen collection. In their pens they had free access to mash and water and were given grain at the same time as the donors.

The volumes of the semen yields for each cock are shown in Table 1. A two-way analysis of variance on these data showed that the differences between cocks were significant ($P<0{\cdot}01$) and that the differences between yields at the various times of collection were also significant ($P<0{\cdot}01$). The greatest yields were found to occur in the late afternoon.

Table 1 VOLUME OF SEMEN YIELDS (MEASURED IN ML.) COLLECTED FROM EACH COCK

Cocks	Times of collection		
	08.30–09.30	12.00–13.00	17.00–18.00
1	0·82	0·48	0·86
2	0·20	0·16	0·47
3	0·48	0·40	0·70
4	0·36	0·30	0·72
5	0·62	0·63	0·71
6	0·14	0·12	0·19
7	0·50	0·01	0·52
8	0·58	0·48	0·46
9	0·28	0·30	0·33
10	0·63	0·77	0·90
11	0·18	0·22	0·51
12	Nil	0·40	0·29

Table 2. TOTAL ABSOLUTE NUMBER OF SPERMATOZOA YIELDED BY EACH COCK

Cocks	Times of collection		
	08.30–09.30	12.00–13.00	17.00–18.00
1	$6{\cdot}333 \times 10^9$	$3{\cdot}302 \times 10^9$	$5{\cdot}798 \times 10^9$
2	1·278	1·16	2·156
3	3·487	3·478	4·473
4	2·991	2·841	6·724
5	3·014	3·255	3·428
6	0·804	0·503	0·938
7	3·208	Nil	2·637
8	3·277	2·674	2·739
9	1·657	1·675	1·705
10	5·068	5·876	7·388
11	1·000	0·900	2·385
12	Nil	2·390	1·538

The total absolute number of spermatozoa yielded by these cocks was also found to vary significantly between cocks ($P<0{\cdot}01$) and between times of collection ($P<0{\cdot}05$) when the data were analysed by means of a two-way analysis of variance. As with volume, the absolute number of spermatozoa was found to be greatest in the late afternoon (Table 2).

Nineteen matings were performed by the control cocks during the hours of observation, and of these thirteen occurred between 17.00–18.00 hours, thus showing that mating activity is high when semen yields are at their best. These results differ from those reported by Parker, McKenzie and Kempster[3]. These workers used a semen collector attached to the cloaca of the cock, which intercepted emissions from cloaca during natural matings and in the periods between matings. They reported that semen volume was greatest in the morning and that the total number of spermatozoa yielded did not differ significantly between morning and afternoon. Attempts to use a semen collector of this type on the cocks at this laboratory have been repeatedly unsuccessful due to contamination with urine and fluids from the cloacal glands, and in this study only direct reflex emissions from the ejaculatory ducts were taken to represent fowl semen, so as to avoid contamination with cloacal fluids and urine. This difference in technique may explain the variance between these results and those of Parker *et al.* (*loc. cit.*).

The relationship between semen yields and mating activity is under further investigation and will be reported elsewhere.

Increase in γ-Radiation from Powdered Milk and Beef, 1953-56

Two apparatuses consisting of cylindrically arranged high-pressure ion chambers (diameter of sample container approximately 1 m., total volume approximately 3 m.^{3}, 20 kgm. nitrogen and carbon dioxide) placed in a low-background laboratory in the rock near the city of Stockholm, and protected in all directions by 1 m. of water and more than 50 m. of granite, have been described in earlier communications[1]. In these, the results of measurements on 306 persons who have had no known contact with other than natural radioactive material of common concentration were also reported. The γ-radiation of human subjects is, in all probability, caused mainly by the potassium-40 content of the body, as has been shown by Burch and Spiers[2].

The same instruments have now (May–July 1956) been used for determination of the possible amount of γ-radiating fission products in powdered milk and beef preserved during the years 1953–56. The potassium content of the powdered milk was carefully determined by the Institute of Radiophysics and the Department of Clinical Biochemistry at Karolinska Sjukhuset, entirely independently. The absorption of the radiation from potassium-40 and cæsium-137 was measured by mixing 500 gm. of potassium chloride and 0·1 μc. of cæsium-137, respectively, in the milk samples, each of which weighed 10 kgm.

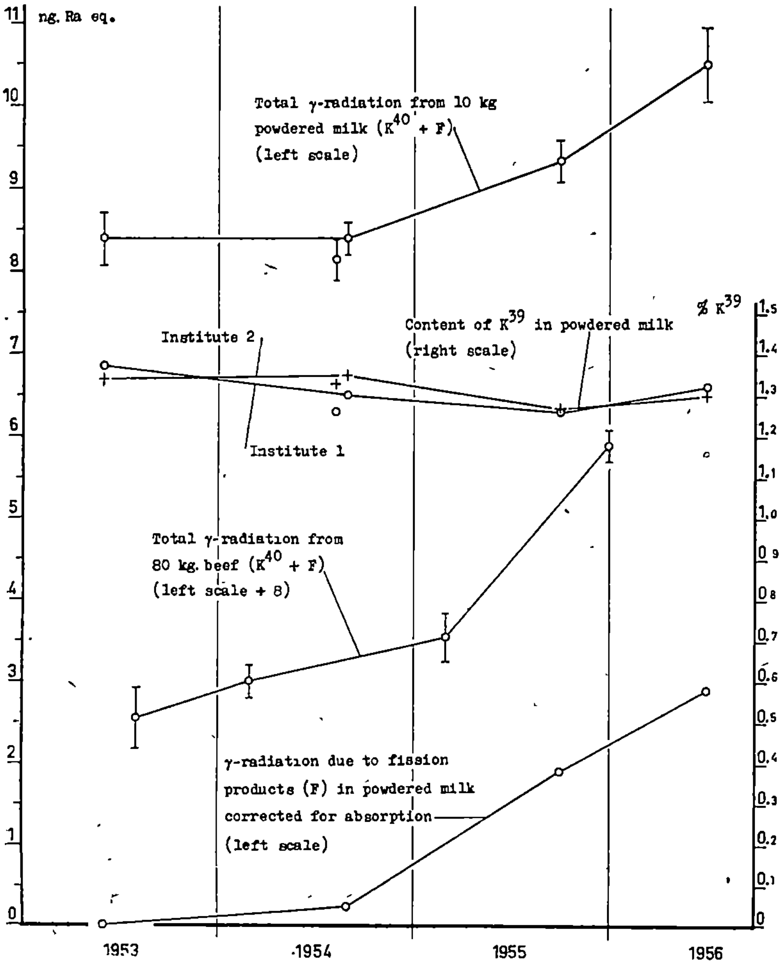

Fig. 1. Radiation from powdered milk and from beef. The observations on powdered milk were all carried out during the period May 18–July 3, 1956, and those on beef during the period July 1–9, 1956. Standard errors are indicated in respect of the observed radiation values

The results of these measurements are plotted in Fig. 1. An increased γ-radiation is obvious, which cannot have been caused by differences in the potassium content. If this increase is due entirely to cæsium-137, the concentration in the natural milk for the samples from 1956 can be calculated to be about 1 × 10^{-4} μc. per litre of milk, that is, 5 × 10^{-5} of the maximum permissible concentration. Because of the comparatively small age of the last samples it seems, however, likely that other fission products may have played the predominant part.

Beef from the years 1953–55 was also examined, each sample consisting of 80 kgm. of meat. The results are also shown in Fig. 1. Since the potassium content is probably the same in all these samples, the higher γ-radiation found in the last year here may also be attributable to an increase in fission products.

Although the quantities observed would probably be too small to cause a detectable increase in the γ-radiation from human subjects consuming milk, a series of children were investigated, and the results compared with the earlier measurements referred to at the beginning of this communication. As seen from Table 1, the two sets of observations (1954 and 1956) are well suited for such a comparison. No significant change could be detected, however, in the average γ-radiation.

The investigation is being continued.

The Serum Gamma-Globulin-Level in Malignant Disease

Very little is known about immunity in relation to malignant disease. In animals there is evidence that resistance develops to transplanted tumours. Lumsden[1] and his co-workers were of the opinion that this resistance was due to the appearance in the serum of certain antibodies. They found that the serum of rats bearing the Jensen rat sarcoma contains a cytotoxin which is greatest in amount in those rats in which tumour regression afterwards occurs. In the human subject the development of humoral resistance to malignant tumours has not been proved conclusively. A number of workers have investigated the serum gamma-globulin-level in patients with malignant disease. Their results can be taken as a measure of the antibody-level since most antibodies are found in association with the gamma-globulin fraction of the serum protein. Petermann and Hogness[2] found that the serum gamma-globulin-level, as estimated by electrophoresis at pH 8·6, was normal in twenty-five patients with carcinoma of the stomach. Miller and Erf[3], using a similar method, found that the serum gamma-globulin was raised in twenty-four patients with carcinoma of the gastro-intestinal tract or breast.

In view of the difference between these results it was decided to perform further electrophoretic investigations on the serum gamma-globulin-level of patients with malignant disease. It was hoped by this means to determine with some degree of certainty whether the antibody-level of the serum changes in the presence of malignant neoplasms.

Twenty-two female patients from the Dartford Group of Hospitals, Kent, suffering from malignant disease, which had been verified by histological examination, were used for the present investigation. The patients were chosen at random and their ages varied from thirty-one to seventy years. The majority of the tumours were situated in the genital or intestinal tracts and were at different stages of development, some being localized while others had metastasized widely. Blood samples were taken from each patient on admission, and only the blood from those patients having normal temperatures, total and differential leucocyte counts, erythrocyte counts and hæmoglobin-levels were used. Blood samples were also taken from twenty healthy females of the same age-group to serve as controls.

The gamma-globulin-level of each of the sera was estimated by first separating the gamma-globulin fraction by paper electrophoresis at pH 8·5 using a veronal buffer. The filter-paper strips were then treated with bromphenol blue and the optical density of the protein dye complex was measured by means of a photoelectric cell. In this manner the percentage of gamma-globulin in relation to the total protein in the serum could be assessed.

No significant difference was found between the serum gamma-globulin-levels of the patients with malignant disease and those of the healthy controls. The gamma-globulin-level in each group averaged approximately 20 per cent of the total serum protein. These findings provide further evidence that the development of malignant disease in man is not associated with an increase in the antibody-level of the serum.

The Expected Blood-Group Antibody, anti-Lu^b

The Lutheran blood group system was first described by Callender and Race[1] in 1946: an antibody, afterwards named anti-Lu^a, was found to react with the red cells of approximately 8 per cent of the English population. The antigen with which the antibody reacts is called Lu^a and can be recognized in the red cells of heterozygous as well as homozygous individuals. The corresponding gene is called Lu^a and an allele Lu^b is postulated. The antigen Lu^b has been recognizable so far only as an absence of Lu^a; thus persons of the phenotype Lu(a−) are presumed to be of the genotype Lu^bLu^b.

The results of testing large numbers of English blood samples with various anti-Lu^a sera have been brought together by Race and Sanger[2], and the following gene and genotype frequencies for the Lutheran system have been calculated.

Genes		Genotypes	
Lu^a	0·0390	Lu^aLu^a	0·0015
		Lu^aLu^b	0·0750
Lu^b	0·9610	Lu^bLu^b	0·9235

An antibody which gives the reactions expected of anti-Lu^b has now been found in the serum of a woman, Mrs. R., who has never been transfused and who has given birth to three healthy children.

In a search for compatible blood for Mrs. R. it was found that her serum agglutinated saline suspensions of the red cells of each of fifteen blood samples. The identity of the antibody was suspected when it was found that Mrs. R.'s own cells reacted very strongly with an anti-Lu^a serum and that her serum reacted less well with Lu(a+) cells than with Lu(a−) cells.

Mrs. R.'s phenotype is as follows: O, MNSs, P+, CcDEe, Lu(a+), K+ k+, Le(a− b+), Fy(a−), Jk(a+ b+). The cells react with an anti-H serum. Dr. R. R. Race kindly tested the cells with anti-U, anti-Vel, anti-Yt^a and anti-Tj^a; in each case a positive reaction was obtained.

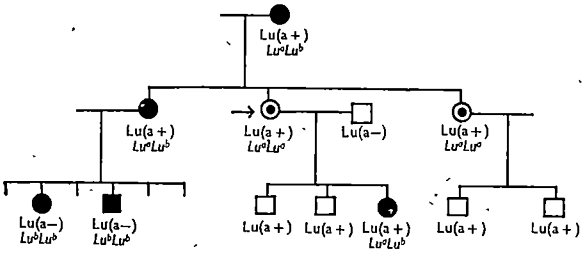

Fig. 1. The Lutheran groups and presumed genotypes of the family of the donor of anti-Lu^b. Arrow, donor; black, Lu(b+); dot, Lu(b−); blank, not tested with anti-Lu^b because of ABO incompatibility

The following findings support the hypothesis that Mrs. R. is of the rare genotype Lu^aLu^a and that her serum contains anti-Lu^b.

(1) Five Lu(a+) and sixteen Lu(a−) blood samples from adults of group O were tested against dilutions of Mrs. R.'s serum. The average titration score for the Lu(a+) samples was 16 (range 12–13); that for the Lu(a−) samples was 28 (range 20–38). The agglutination reactions were 'scored' as suggested by Callender and Race[1].

(2) Mrs. R.'s serum reacted with all of 532 unselected samples from adults of group O. From 322 of these, 64 samples which reacted weakly were selected for testing with an anti-Lu^a serum: 17 (26·56 per cent) were Lu(a+). It can be calculated that on a sample of 64, the standard error of the expected percentage (7·65) of Lu(a+) bloods is 3·3. Thus the deviation from the expected percentage is five times the standard error.

(3) Fifty blood samples known to be of the phenotype Lu(a+) were tested; one of these (from Mrs. L.) failed to react with Mrs. R.'s serum. Mrs. L.'s serum does not react with Lu(a−) cells.

(4) The blood groups of a number of Mrs. R.'s relatives were determined. Their reactions with anti-Lu^a and with Mrs. R.'s serum are shown in the pedigree (Fig. 1). One sister is of the presumed genotype Lu^aLu^a, since her cells react with anti-Lu^a but fail to react with Mrs. R.'s serum; her serum does not react with Lu(a−) cells.

Mrs. R.'s cells give a higher titration score with an anti-Lu^a serum than do the cells of her mother or those of her children.

(5) Callender and Race[1] described a family (Family 5) in which both parents and all four children were Lu(a+). As there seemed a good chance of finding a homozygote among the children, the family has been tested again: one of the children fails to react with Mrs. R.'s serum and is presumably of the genotype Lu^aLu^a. The cells of both parents react with Mrs. R.'s serum.

The antibody in Mrs. R.'s serum reacts strongly at 20° C. and less well at 37° C., as a saline agglutinin. The agglutinates are firm; but many free cells are present. The reaction is not inhibited by the saliva of secretors or non-secretors. At 37° C. the antibody gives a weak indirect anti-human globulin reaction, but only with Lu(a−) cells. Following the intravenous injection of 1 ml. of Lu(a−) red cells the antibody increased in avidity.

We should like to thank Dr. P. L. Mollison and Dr. R. R. Race for their help during this investigation, and Dr. Gertrude Plaut and Dr. T. E. Cleghorn for supplying large numbers of blood samples. Dr. A. Davis and Dr. R. J. Drummond kindly obtained blood samples from Mrs. R.'s family and from Family 5.

Two Stages in the Formation of Active Plasma Thromboplastin

ALTHOUGH the exact role of calcium in the complex mechanism of blood coagulation is still in some dispute, it is certain that it is a basic element in some of the interactions taking place between the various blood-clotting factors which finally lead to the formation of the prothrombin-converting factor, plasma thromboplastin[1]. Recently, we[2] described an ether-precipitation method for the separation of the latter. Further work, reported herein, on the relation between this important blood-clotting factor and calcium has revealed the presence of two stages in the production of a fully active plasma thromboplastin.

A study on the effect of calcium chloride, calcium gluconate, calcium lactate, strontium chloride and magnesium chloride in the generation of plasma thromboplastin[3] showed that the latter four compounds and particularly magnesium chloride are inferior to calcium chloride (Table 1) in this respect.

Plasma thromboplastin was isolated using ether[2]. The product was dissolved in 0·9 per cent sodium chloride and its activation with each of the above compounds was determined by incubating the solution with an equal volume of 0·025 *M* of the compound under trial. At intervals (Table 2), 0·1 ml. of the mixture was taken together with 0·1 ml. of 0·025 *M* calcium chloride and both were added simultaneously to 0·1 ml. human citrated plasma at 37° C., recording the clotting time. The results presented in Table 2 show that strontium and magnesium chloride have no activating effect, while

Table 1. CALCIUM, STRONTIUM AND MAGNESIUM SALTS IN THE FORMATION OF PLASMA THROMBOPLASTIN

Compounds used	Clotting time of substrate in sec. M/ 5	10	20	40	80
Calcium chloride	15	10	8½	8	9½
Calcium gluconate	—	—	10	10	11

Strontium chloride	19	15	12½	12	16
Magnesium chloride*	—	54	50	21	23

* Maximum activity was reached after 18 min. incubation, instead of 6 min. with the other compounds.

Table 2. INCUBATION OF ISOLATED PLASMA THROMBOPLASTIN WITH CALCIUM, STRONTIUM AND MAGNESIUM SALTS

Compound used (0·025 *M*)	Clotting time of substrate in sec. Period of incubation in min. 0	1	2	4	8
Calcium chloride	26	17	14	14	14
Strontium chloride	23½	23½	23½	24	24
Magnesium chloride	24	24	24	25	25
Calcium lactate	24	21½	20	20½	21
Calcium gluconate	24	22	21	21	21½

calcium lactate and gluconate activate plasma thromboplastin although to a lesser degree than calcium chloride.

From these experiments the development of a fully active plasma thromboplastin seems to be achieved in two stages. In the first stage (or formation stage) the necessary blood-clotting factors interact to form plasma thromboplastin. For this, calcium is needed but can be replaced to a lesser degree by strontium; magnesium is a very poor substitute. In the second stage (or activation stage) the plasma thromboplastin formed is activated by the calcium, thus acquiring its full strength; strontium and magnesium ions cannot replace calcium. Additionally, at this stage the ionic state of the latter appears to affect the degree of activation produced, both calcium lactate and gluconate being less powerful than calcium chloride.

During the process of blood coagulation or in the thromboplastin generation test, the first stage could not be distinguished from the second stage, which follows instantaneously. However, ether-precipitation seems to isolate the non-activated plasma thromboplastin, that is, the product of the first stage. This would explain the apparent low recovery obtained[2]. When the isolated plasma thromboplastin is incubated with calcium chloride, a completely active plasma thromboplastin is obtained after two minutes (Table 2) and the recovery is thus practically doubled in amount.

Estimation of Small Proportions of Fœtal Hæmoglobin in Blood

The detailed characterization of blood samples containing the genetically determined abnormal hæmoglobins[1] requires a sensitive method for estimating small traces of fœtal hæmoglobin (Hb-F) in the presence of excess of other hæmoglobins. We have applied the ultra-violet spectrographic method[2] to residues of partially denatured hæmoglobin obtained by a modified Singer procedure[3], with particular attention to the following questions: (*a*) Is the residue authentic hæmoglobin? (*b*) Does it contain fœtal hæmoglobin, and, if so, in what proportion? Residues from normal adult blood, artificial mixtures of adult hæmoglobin (Hb-A) and fœtal hæmoglobin in varying proportions, and pathological blood samples, containing varying proportions of fœtal hæmoglobin by our standard methods, have been studied.

In order to obtain residues of manageable optical density when the proportion of fœtal hæmoglobin is small, our test is carried out by mixing equal volumes of 5 per cent oxy-hæmoglobin solution and *N*/6 sodium hydroxide, giving a final *p*H of about 12·8, and neutralizing in the usual way, but after ¾ min.

* Measured against Haldane standard with Ilford 625 filter.
† Mean values for 12 normal adult bloods.

The residue from normal adult blood, examined as carboxyhæmoglobin, has a protein/hæm ratio of about 2, as evaluated from the relative absorption intensities of protein and hæm components at selected wavelengths. By the fine-structure criterion[2], the protein is entirely of the adult type in the many samples examined. The spectrographic measurements do not appear to be seriously affected by the presence of free globin.

Table 1 records the results for known mixtures of adult and fœtal hæmoglobin covering a wide range of composition. The proportion of fœtal hæmoglobin in the residue is estimated spectrographically, and that in the whole blood calculated from the percentage residue, after correcting the latter figure for the altered protein/hæm ratio. When the fœtal hæmoglobin is greater than 10 per cent, the residue is a close approximation to the actual fœtal hæmoglobin content. When the fœtal hæmoglobin is less than 10 per cent, however, the residue is higher than the true fœtal content, is no longer pure, fœtal-type hæmoglobin, and its protein/hæm ratio greatly exceeds unity (cf. ref. 4). The data in Table 1 show that errors in the estimation of fœtal hæmoglobin, based on the uncorrected ¾-min. residue, increase progressively as the proportion of fœtal hæmoglobin falls to the 1 per cent level. Similar observations have been made for unmodified Singer 1-min. residues. If corrections are applied for the actual percentage of fœtal hæmoglobin in the residue and for the protein/hæm ratio of the latter, a more accurate estimate is obtained.

Working in this way, it is possible to estimate fœtal hæmoglobin with some confidence down to a level of about 1 per cent of the whole-blood pigment, both in artificial mixtures and in pathological blood samples. At this limit of sensitivity no fœtal hæmoglobin has been found in any of the normal adult hæmoglobins which have been examined. If present, its proportion would seem to be less than 1 per cent, as is claimed by some other workers[5]. Various pathological bloods have yielded more than 2 per cent of residue, but not necessarily containing fœtal hæmoglobin. On the other hand, its presence has been confirmed in other, similar residues when the standard methods do not reveal it in the total hæmoglobin preparations. Examples are given in Table 1, including blood from a child with Albers–Schönberg disease (kindly provided by Prof. C. E. Dent), also a Burmese mother and child with thalassæmia-like anæmias, possessing traces of fœtal hæmoglobin, and small fractions (7 and 14 per cent) of hæmoglobin resembling Hb-E on electrophoresis.

It is evident that the simple and convenient Singer method gives residues of analytical value when the proportion of fœtal hæmoglobin in the sample is more than 10 per cent. When the proportion of fœtal hæmoglobin is less than 10 per cent, however, more laborious examination of the residue is required to detect and estimate the fœtal hæmoglobin which may be present.

We are grateful to the Colonial Medical Research Committee for a grant enabling one of us (M. E.) to assist in this work.

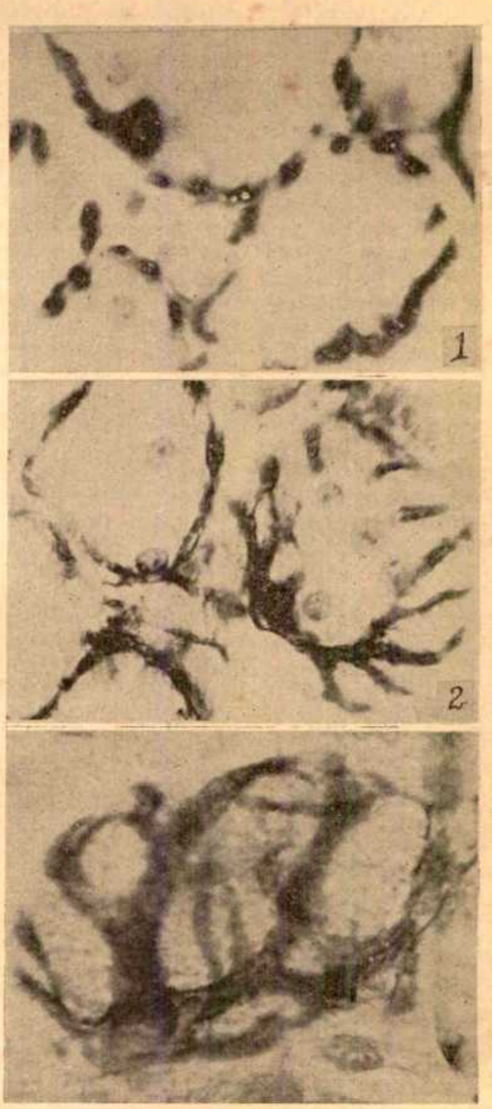
Localization of Alkaline Phosphatase in the Submaxillary Gland of the Rat

IN spite of the extensive studies which, in recent years, have been made on the histochemical distribution of alkaline phosphatase, there is a sparseness of data concerning the salivary glands, in particular the submaxillary gland. Gomori[1] commented briefly on the absence of alkaline phosphatase in the parenchymal cells of the salivary glands of man and nine other species, including rat, while Bourne[2] for the guinea pig submaxillary gland reported diffuse staining of nuclei and cytoplasm of the alveolar cells. Deane[3] found alkaline phosphatase localized in the 'basal ergastoplasm' of the serous cells of two submaxillary glands of monkey, and a similar finding was reported by Noback and Montagna[4] for the rat and mouse. The latter workers also mention a heavy reaction of the basement membrane and at other places; but these observations are clouded by the use of excessive times of incubation.

My own paraffin-embedded material of rat submaxillary glands was fixed either in cold acetone or alcohol or preserved by freeze-substitution. Results were essentially identical after any of these methods; but the acetone-fixed material gave the clearer pictures. Alkaline phosphatase was demonstrated both by Gomori's method (substrate: sodium β-glycero-phosphate) and by an azo-dye method (substrate: sodium α-naphthyl-phosphate). With Gomori's method, a two-hour incubation produced a heavy blackening around and at the base of most acini, thus apparently confirming the observations of earlier workers; but widespread nuclear staining indicated that diffusion was complicating the issue and erroneous interpretation possible[5]. To guard against this, incubation was reduced to 15–30 min. Examination of sections thus treated reveals a definite pattern of this alkaline phosphatase positive material at the base of the acini. It rarely goes right round the acinus but is arranged in an interrupted fashion inside the basement membrane, in the form of dark dots or small rings, short oblique narrow bands or bands running around the circumference of the acinus for a limited stretch (Figs. 1 and 2). Here and there the alkaline phosphatase positive material encloses a nucleus, often oval, distinct from those of the acinar cells and lying against, but inside, the basement membrane. The nature of this pattern, which is suggestive of sections through an irregularly branching network, becomes clear when tangential sections



Rat submaxillary glands fixed in acetone and stained by Gomori's method for alkaline phosphatase.
Fig. 1, Incubation time, 30 min. (× 1,010); Fig. 2, incubation time, 30 min. (× 890); Fig. 3, incubation time, 15 min. (× 1,500)

of acini are seen, showing that it is the 'basket' or myo-epithelial cells which are specifically displayed (Fig. 3). The nucleated parts of these cells when seen from the flat have often a triangular shape from which long branching and tapering processes emanate. The length and width of these agree with the sectioned appearances of the alkaline phosphatase positive material around the acini. It is worth noting that the reaction does not give a homogeneous appearance to the cytoplasm, but rather a mottled one, very often combined with a fibrillar pattern (Figs. 2 and 3).

Similar, but much smaller and less extensively ramifying, alkaline phosphatase positive basket cells were also seen in the very short intercalated ducts which are present in these glands. The remaining portions of the duct system were alkaline phosphatase negative. Blood capillaries gave—as is usual with rat tissue—an irregular and erratic reaction. When alkaline phosphatase was visualized by the azo-dye method, the result was the same.

This almost specific localization of alkaline phosphatase in the myo-epithelial cells of the rat submaxillary gland links up satisfactorily with the findings of Dempsey, Bunting and Wislocki[6], who demonstrated the presence of alkaline phosphatase in the myo-epithelial cells of the mammary gland of rat, and of Silver[7], who showed that the same holds for the mammary gland of sheep and rabbit and the sheep's parotid, but it still remains to be seen whether it is a general property of myo-epithelium.

My thanks are due to Dr. F. Jacoby for all his suggestions and helpful criticism, and to Mr. L. Jones for the microphotographs.

Addendum.—Since this communication was submitted for publication, my attention has been directed to a letter by R. L. Holmes (*Nature*, **178**, 311 (1956)).

Antagonists of the Action of Reserpine on Smooth Muscle

We have recently directed attention to the fact that citrate antagonizes reserpine inhibition of contractions induced in the guinea pig ileum by acetylcholine chloride, histamine acid phosphate, serotonin and barium chloride[1]. A consideration of the general pharmacology of reserpine has led us to believe that this substance may have a general non-specific depressant effect upon contractile tissue[1,2].

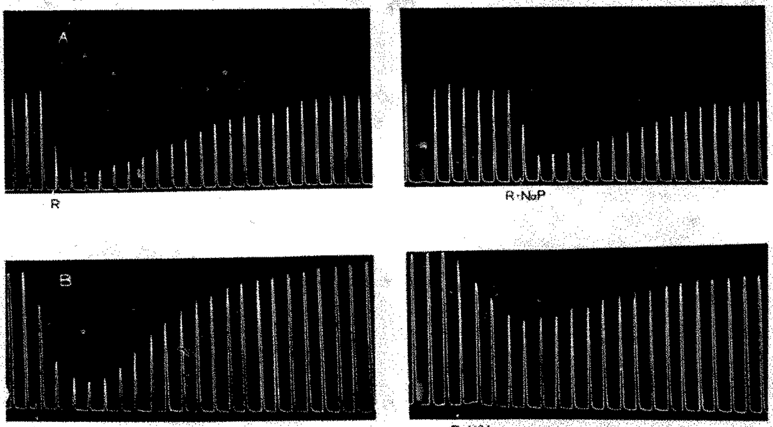

Fig. 1. (*A*) All contractions produced by 0·25 µgm. per ml. acetylcholine chloride. (*B*) All contractions produced by 0·20 µgm. per ml. histamine. At *R*, 30 µgm. per ml. reserpine added. At *R* + *NaP*, 30 µgm. per ml. reserpine and 1 mgm. per ml. sodium pyruvate added. At *R* + *KGA*, 30 µgm. per ml. reserpine and 1 mgm. per ml. α-keto-glutaric acid added

Since reserpine non-selectively antagonizes contractions due to acetylcholine chloride, histamine acid phosphate, serotonin and barium chloride in the guinea pig ileum, it appears to be affecting underlying mechanisms connected with the production and utilization of the energy necessary for the drug-induced contractions rather than specific receptors. These mechanisms probably involve the breakdown and resynthesis of carbohydrate through the glycolytic and tricarboxylic acid cycles. It seemed worth while, therefore, investigating the influence of adding known intermediates of carbohydrate metabolism to the isolated guinea pig ileum immediately before addition of reserpine

The ileum was stimulated by either acetylcholine chloride (0·2–1·0 µgm. per ml.), histamine acid phosphate (0·1–1 µgm. per ml.), serotonin (15–40 mgm. per ml.) or barium chloride (0·2 mgm. per ml.) at 3-min. intervals. Reserpine was added 1 min. before the spasmogen and the metabolite 5 sec. before reserpine. All metabolites were tested over the dose-range, 125 µgm.–1 mgm. per ml. The following were ineffective as reserpine antagonists: glucose-1-phosphate, fructose-1,6-diphosphate, fructose-6-phosphate, pyruvate (Fig. 1), fumarate, succinate and adenosine triphosphate. The following were very active: citrate, *cis*-aconitate and α-keto-glutarate (Fig. 1). Malate and oxaloacetate had intermediate activity. Maleic acid (the *cis*-isomer of fumaric acid) at doses of 500 µgm. or 1 mgm. per ml. was very active. Removal of calcium from the bath fluid by disodium dihydrogen versenate did not produce antagonism to reserpine.

The possibility of release of histamine or acetylcholine chloride by the metabolites was excluded by repeating the experiments using, where appropriate, Tyrode's solution containing either atropine sulphate (100 µgm. per litre) or mepyramine maleate (200 µgm. per litre).

Since the most active reserpine antagonists are intermediates of the tricarboxylic acid cycle, it seems not unlikely that this is a site of action of the alkaloid.

Bleaching of Visual Purple in Solutions of Inorganic Salts

It has been stated that visual purple can be salted out of solution with magnesium and sodium sulphates[1,2]. In the present work, an attempt was made to repeat this, using moderately concentrated visual purple solutions. No precipitation occurred; but it was found that in the presence of large amounts of ammonium sulphate, ammonium chloride, magnesium sulphate and sodium sulphate the bleaching of visual purple was modified.

Solutions of frog visual purple were prepared by the addition of 1 per cent aqueous digitonin solution to whole washed retinæ. The extracts were buffered to *p*H 8·0–8·6 by the addition of sodium tetraborate solution. These extracts were then concentrated about 3–4 times *in vacuo* at low temperature, bringing the D_{500} from 0·2 to 0·6–0·8.

Saturation of these solutions with ammonium sulphate (making the salt concentration about 3·3 *M* and bringing the *p*H to about 7·2) produced only a faint opalescence. On exposure to light, such solutions bleached to a stable orange photo-product. The absorption spectra for a bleached and unbleached solution are shown respectively by curves *A* and *B* of Fig. 1. The $\lambda_{\text{max.}}$ of the unbleached solution lies at 495 mμ, and that of the bleached solution at 470 mμ. The true pigment maxima may be obtained by calculating the $D_{\text{min.}}/D_{\text{max.}}$ ratios and correcting the observed maxima accordingly[3]. When this is done, the corrected $\lambda_{\text{max.}}$ of the unbleached and bleached solutions are seen to lie at 501 mμ and 482 mμ respectively.

The orange photo-product was clearly not indicator yellow, for the $\lambda_{\text{max.}}$ of that substance, even in acid solution, is no higher than 440 mμ. If another portion of the same visual purple solution was bleached prior to saturating with ammonium sulphate a normal alkaline indicator yellow curve was obtained. This is shown in curve *C*, Fig. 1. The 'difference spectrum' of the orange photo-product is obtained by subtraction of curve *C* from curve *B*. This is shown in Fig. 2. The $\lambda_{\text{max.}}$ lies at 485 mμ, thus confirming the value of 482 mμ calculated directly from the solution. Subtraction of curve *C* from curve *A* yields a difference spectrum for visual purple. This also is shown in Fig. 2.

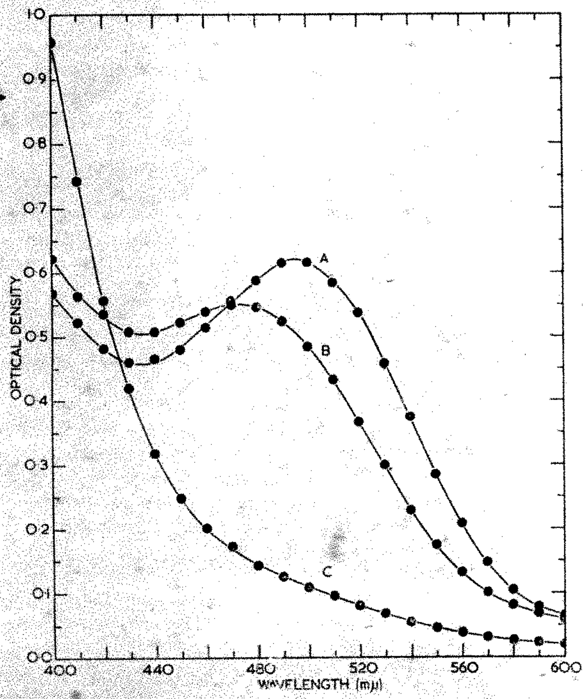

Fig. 1. Absorption spectra of visual purple extracts saturated with ammonium sulphate.
Curve *A*, Extract saturated with ammonium sulphate (*p*H = 7·19, $D_{\text{min.}}/D_{\text{max.}}$ = 0·74); curve *B*, extract after a 15 min. exposure to white light ($D_{\text{min.}}/D_{\text{max.}}$ = 0·91); curve *C*, the same visual purple extract bleached prior to saturating with ammonium sulphate

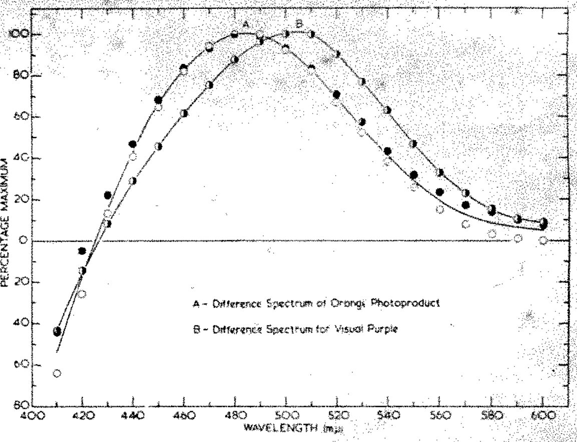

Fig. 2. Difference spectra of the orange photo-product and of visual purple.
●, Curve *B* minus *C* (Fig. 1); ○, difference spectrum, as above; the data are obtained from a similar extract (*p*H = 6·96); ◑, curve *A* minus *C* (Fig. 1)

In darkness at 20° C. the orange photo-product slowly transformed to indicator yellow over a period of about 48 hr. Heating the solution for 15 min. at 60° C. caused destruction of the orange photo-product, accompanied by the formation of a pale yellow gel. If the salt concentration were reduced by the addition, in darkness, of an equal volume of 4 per cent aqueous digitonin solution the orange photo-product changed to alkaline indicator yellow. The transformation was complete in about 20 min.

When concentrated visual purple solutions were saturated with magnesium sulphate, sodium sulphate or ammonium chloride, then exposed to light, the orange photo-product was formed initially but was more unstable. After about ½ hr. in darkness, only indicator yellow was left in solution.

Whenever these solutions were diluted or were stored for any length of time, unpredictable changes in opalescence occurred. It was often difficult, therefore, to attain the desired accuracy in the measurement of absorption spectra.

Under certain conditions visual purple is known to produce stable orange photo-products. At low temperatures, Lythgoe[4] found that visual purple bleached to form transient orange, $\lambda_{\text{max.}}$ estimated at about 470 mμ [5]. At room temperatures, visual purple in a dried gelatin film bleaches to meta-rhodopsin, $\lambda_{\text{max.}}$ 480 mμ [6].

Judged by its $\lambda_{\text{max.}}$ and its absorption properties, the orange photo-product of the present work is identical with meta-rhodopsin. One difference, however, may be noted: meta-rhodopsin which has been produced in a dried film may be converted by wetting to indicator yellow ('retinene$_1$ and protein') and 'regenerated rhodopsin'[6]. The analogous process in the present work, reduction of salt concentration by dilution, completely converts the orange photo-product to indicator yellow, there being no sign of 'regeneration'.

It is interesting to note that Lythgoe and Quilliam[7] found that the velocity constant for the thermal conversion of visual purple to indicator yellow at 36° C. was diminished about five times in the presence of 2 *M* sodium chloride. The effect was probably due to the stabilization by salt of an orange intermediate.

Amino-Acid Sequence in a Fraction of *Bombyx* Silk Fibroin

When an aqueous solution of the fibroin of *Bombyx mori* is acted upon by chymotrypsin, a precipitate is formed[1] through the specific action of the enzyme on the α-carboxyl groups of the tyrosine residues. This precipitate contains 62 per cent of the total nitrogen and represents 58 per cent of the total weight of the protein. It consists almost entirely of glycine, alanine, and serine, together with a little tyrosine, the molar ratios of glycine to alanine to serine being 3 to 2 to 1. The fraction has a high degree of crystalline order as shown by X-rays, and a molecular weight of about 4,000.

A detailed analysis[2] of this chymotryptic precipitate has established its formula as $\mathrm{Gly.}_{29}$ $\mathrm{Ala.}_{20}$ $\mathrm{Ser.}_{9}$ $\mathrm{Tyr.}_{1}$, and the C-terminal position has been shown to be occupied mainly by tyrosine[3].

We have recently investigated the sequence of the amino-acids in the chymotryptic precipitate. This investigation has been greatly facilitated by the absence from hydrolysates of the chymotryptic precipitate of Gly.Gly, which could not be detected even after careful search in a number of separate experiments. The absence of Gly.Gly bonds, and the analytical values showing that one half of the total residues are glycyl, mean that every alternate residue must be glycine. If the seryl residues are evenly spaced within the molecule, they will occupy every sixth position, and a repeating hexapeptide sequence of the form Ser.Gly.Ala.Gly.Ala.Gly would be a dominant feature of the molecule.

By using the N-acyl to O-acyl transformation that occurs at the seryl residues when proteins are dissolved in anhydrous mineral acids[4,5], followed by specific fission at these residues, we have been able to isolate and identify 36 per cent by weight of the chymotryptic precipitate as this hexapeptide in the form of its dinitrophenyl derivative. The yield would undoubtedly be considerably greater, but for the difficulty of preventing unwanted fission and re-combination during the treatment.

The products of the partial hydrolysis of the chymotryptic precipitate have also been examined, the dinitrophenylated mixtures being separated by column chromatography into their constituents, which were estimated quantitatively, a maximum recovery of 87 per cent, on a nitrogen basis, being obtained. The only dipeptides recovered were Ala.Gly, Gly.Ala, Ser.Gly, and a very small amount of Ala.Ala. The only tripeptides obtained were Gly.Ala.Gly, Ala.Gly.Ala, and Ser.Gly.Ala. The molar ratio of Ala.Gly to Gly.Ala in hydrolysates of periods longer than five hours was consistently 2 to 1. Serine was never recovered in peptide form except as the N-terminal residue, and was followed always by glycine, and not by alanine.

The N-terminal amino-acid residues of the chymotryptic precipitate have been determined by treating it with 1-fluoro-2 : 4 dinitrobenzene, hydrolysing, and separating and estimating the dinitrophenyl-amino-acids. Glycine occupied 84 per cent of the N-terminal amino positions, serine 10 per cent and alanine 4 per cent. Dinitrophenyl-Gly.Ala, dinitrophenyl-Gly.Ala.Gly, and dinitrophenyl-Gly.Ala.Gly.Ala were isolated from the N-terminal sequence, and, together with the recovered dinitrophenyl-glycine, they constituted 78·5 per cent of the total N-terminal glycine.

Consideration of all the evidence leads to the conclusion that the chymotryptic precipitate is composed mainly of a repeating sequence of the form $\mathrm{Ser.Gly.(Ala.Gly)}_n$, where *n* is usually 2, and must have, by requirement of the analytical data, an *average* value of 2. In addition to this principal constituent, a small amount of Ala.Ala is present, together with a C-terminal tyrosine residue and an N-terminal sequence in which mainly glycine provides the N-terminal amino residue.

The chymotryptic precipitate is thus composed of an aggregation of sections of the fibroin molecule, these sections having the formula

$$\mathrm{Gly.Ala.Gly.Ala.Gly.[Ser.Gly.(Ala.Gly)}_n\mathrm{]}_8 \\ \mathrm{Ser.Gly.Ala.Ala.Gly.Tyr.}$$

where *n* is usually 2, and always has a mean value of 2.

A detailed account of this work has been prepared, and is being submitted for publication elsewhere.

Interrelation between Photosynthesis and Respiration in the Marine Flagellate, *Dunaliella euchlora*

The photosynthetic assimilation of carbon-14 from the external medium by unicellular algae appears to proceed at a rate which is equivalent to the plants' net photosynthesis (the difference between photosynthesis and respiration). This was demonstrated in experiments in which the assimilation of carbon-14 was compared simultaneously with the evolution of oxygen[1], and was most apparent under conditions of low light intensity or nutrient depletion where respiration approached or equalled photosynthesis. For example, at or below the compensation-level no significant uptake of carbon-14 could be detected in 24 hr. despite the occurrence of measurable photosynthesis by oxygen production.

Two possible physiological explanations for this behaviour have been considered. These are: (1) that newly assimilated carbon serves as an immediate substrate for respiration; (2) that respiratory carbon dioxide is used preferentially to external carbon dioxide for photosynthesis. The first of these explanations appears to be contradictory to the findings of Calvin[2] and Weigl *et al.*[3], who have reported that newly assimilated carbon-14 does not immediately enter the respiratory cycle as long as the plants are photosynthesizing.

The second possibility may be investigated by a simple experiment in which organisms are grown in a medium containing carbon-14 for a sufficient number of generations so that essentially all their carbon becomes uniformly labelled with the tracer. If the cells are then removed from their external carbon-14 source and resuspended in fresh medium, any respiratory loss of carbon must be accompanied by a loss of carbon-14 activity by the organisms. The failure to detect such a loss during photosynthesis would clearly demonstrate the re-assimilation of respiratory carbon dioxide. The details of such an experiment are as follows.

A bacteria-free culture of *Dunaliella euchlora* was inoculated into 1·5 litres of enriched sea water medium deficient in nitrogen (0·001 per cent potassium nitrate), giving an initial cell concentration of 1,500 cells/ml. 10 μc. of $^{14}CO_3$ were added and the cultures exposed to approximately 800 foot-candles of illumination at 20° C. At the same time a duplicate culture containing no carbon-14 was inoculated. After two days the cultures contained 21,000 cells/ml. and, for practical purposes, all the carbon of the cells in the isotope-enriched culture was uniformly labelled with the tracer. Exponential growth continued for four days and growth stopped after the fifth day. During the growth period sufficient carbon dioxide was added daily to keep the *p*H below 8·0. This was not necessary after growth had stopped. The growth-curve for the two duplicate cultures is shown in Fig. 1, each point representing the mean concentration of cells in the two cultures.

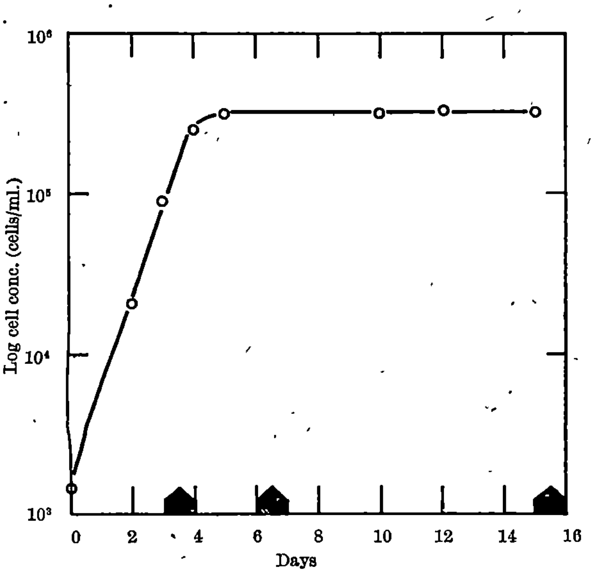

Fig. 1. Growth curve of duplicate *Dunaliella* cultures. Arrows denote days on which experiments were performed.

Table 1. The Loss of Activity in *Dunaliella* tagged with Carbon-14 in the Light and Dark in relation to Photosynthesis and Respiration

Age of culture (days) (see Fig. 1)	*P* (ml. O_2/l./hr.)	*R* (ml. O_2/l./hr.)	*P* : *R*	% Loss activity/24 hr. Light	% Loss activity/24 hr. Dark
3	0·36	0·03	12·0 : 1	−0·3*	20·9
6	0·09	0·02	4·5 : 1	1·6*	22·9
15	0·03	0·015	2·0 : 1	1·5*	20·0

* Attributable in each case to random counting error.

On the third, sixth and fifteenth days aliquots of the culture tagged with carbon-14 were centrifuged. The cells were then washed in filtered sea water and resuspended in the filtered medium of the culture containing no carbon-14, adjusting the density to give 25,000 cells/ml. The tagged cells were thereby removed from their external source of carbon-14 but retained in a medium physiologically identical with that in which they had grown. The *p*H was adjusted to 7·0–7·5 by the addition of carbon dioxide and the new cell suspension siphoned into 35-ml. glass-stoppered bottles.

Half the bottles were used for the determination of photosynthesis and respiration by measuring the change in dissolved oxygen concentration (Winkler method) in the light (800 f.c.) and in the dark after six hours. The increase in oxygen in the light represents net photosynthesis ($P-R$), the decrease in the dark represents respiration (R) and the difference between the two is considered equivalent to total photosynthesis (P).

Of the remaining bottles, one-third were filtered immediately, one-third exposed to 800 foot-candles illumination for 24 hr. and filtered, and one-third kept in the dark for 24 hr. and filtered. The filters were then dried and their radioactivity determined. All the above measurements were made in triplicate, and the mean values are given in Table 1. The data show that the cells tagged with carbon-14 did not lose a significant amount of carbon during 24 hr. of exposure to light, while those kept in the dark for the same length of time lost approximately 20 per cent of their carbon.

Measurements of the oxygen assimilation of *Dunaliella* following its removal from light have shown that respiration proceeds at a rapid and constant rate during the first 24 hr., after which the process slows down markedly. Kok[4] observed the same behaviour in *Chlorella*, which respired as much as 15 per cent of its dry weight (or a comparable fraction of its carbon) in 20 hr., following which the rate of oxygen uptake "declined to a low and steady level of endogenous respiration".

The loss of 20 per cent of the carbon-14 content of the cells in the dark over 24 hr. may therefore be reasonably attributed to respiration. Since the rate of oxygen uptake remains constant throughout that period, it also seems reasonable to assume that respiration occurred at essentially the same rate in the organisms exposed to the light, particularly in view of the evidence presented by Brown[5] that respiration is independent of light.

Since all carbon in the organisms was tagged with carbon-14, any measurable respiration would result in a loss of activity to the cells. The fact that such a loss was not detected in the light must be interpreted to mean that somewhere within the respiratory cycle the carbon was re-assimilated by photosynthesis. This process appears to have occurred with 100 per cent efficiency regardless of the rate of photosynthesis or the ratio of $P : R$. It is noteworthy that the respiratory carbon dioxide was preferentially used despite an external partial pressure of carbon dioxide more than four times as great as that of normal sea water. Even during the period of maximum photosynthesis (on the third day) carbon dioxide assimilation did not exceed 15 per cent of the total carbon dioxide available in the medium.

These experiments provide no clue as to the biochemical state of the recycled respiratory carbon. They recall the suggestion of Franck[6], Gaffron[7] and others of a common intermediate pool for photosynthesis and respiration. However, a case may also be made on purely physical grounds for the successful competition of respiratory versus external carbon dioxide at the chloroplast. The latter is perhaps more compatible with the observations of Brown[5], who was able to neglect the preferential utilization of photosynthetically produced oxygen in his respiration experiments with *Chlorella*, indicating that the two processes are not universally linked at an intermediate level.

Insecticide Resistance in *Anopheles gambiae* Giles: a Case of Simple Mendelian Inheritance

A STRAIN of *Anopheles gambiae* from Northern Nigeria, highly resistant to dieldrin and cross-resistant to the related chlorinated hydrocarbon insecticides (chlordane, aldrin, isodrin, endrin and gamma-BHC), but still susceptible to DDT, has recently been colonized in this Institute and the degrees of resistance to these insecticides reported[1]. A colony of the same species from Lagos and susceptible to all these insecticides has also been maintained in the same Institute for some four years.

Crossings between the two strains have now thrown light on the mechanism of the inheritance of this particular type of resistance in *A. gambiae*.

Crossings have been possible both ways (male × female and female × male), and result in hybrids which are identical and homogeneous so far as their susceptibility to insecticides is concerned (so far only gamma-BHC and dieldrin have been tried).

Table 1. MEDIAN LETHAL CONCENTRATIONS (PERCENTAGES IN RISELLA OIL) OF DIELDRIN AND GAMMA-BHC WHEN SUSCEPTIBLE, RESISTANT AND HYBRID STRAINS OF *Anopheles gambiae* ARE EXPOSED FOR 1 HR.

	Susceptible strain (*S*)		Resistant strain (*R*)		Hybrid *R*♀ × *S*♂		Hybrid *R*♂ × *S*♀	
	♀	♂	♀	♂	♀	♂	♀	♂
Dieldrin	0 08	0 05	>4 0	>4·0	2·6	1 5	2·3	1 6
Gamma-BHC	0 007	0·006	0 21	0 18	0·053	0 038	0 052	0 038

Homogeneity is indicated by the narrow range of dosages of these insecticides necessary to kill all these hybrids, the dosages being between those necessary to kill the susceptible strain and those necessary to kill the resistant strain. Table 1 shows the $LD50$ for the two strains and the two hybrids when exposed for 1 hr. to solutions of dieldrin and gamma-BHC in Risella oil[2]. The $LD50$ of dieldrin was impossible to determine for the resistant strain when exposure for 1 hr. only was made, as a saturated solution of this insecticide (4 per cent) gave no kill. By increasing the exposure time, however, it has been shown to be about 800 times as resistant to dieldrin when compared with the Lagos strain, and is also some twenty-six times as resistant to gamma-BHC [1]. The hybrids proved to be some thirty times as resistant to dieldrin and seven times to gamma-BHC. The males of both strains were slightly more susceptible than the females.

Thus it has been possible to choose two separating dosages of both insecticides, one killing all susceptibles but not hybrids or resistants, and the other killing all hybrids and susceptibles but not resistants. These dosages for an exposure of 1 hr. are 0·33 and 4·0 per cent dieldrin and 0·025 and 0·1 per cent gamma-BHC.

The usual method of determining the number of genes involved in a particular character by ascertaining the sort-out in the F_2 generation was not possible with these two strains of *A. gambiae*, because the F_1 hybrids were almost sterile. Though eggs were readily laid by the hybrid females, only a very occasional one proved to be viable. The sterility was eventually shown to be in the male hybrid.

It has been possible, however, to back-cross the two hybrid females with the parent susceptible and resistant males. The offspring of the four possible back-crosses have been exposed to the established separating dosages and the resulting proportions of susceptibles, hybrids and resistants obtained are given in Table 2. These results show quite conclusively that the inheritance of resistance to the dieldrin–chlordane–gamma-BHC group of insecticides is monofactorial with incomplete dominance.

A complete proof of this 50 : 50 separation in the offspring of the back-cross was given when the offspring of the back-cross of the hybrid female (*R*♀ × *S*♂) with the susceptible male parent were exposed to the dosage eliminating susceptibles and the survivors

Table 2. PERCENTAGES OF SUSCEPTIBLES, HYBRIDS AND RESISTANTS RESULTING FROM THE FOUR BACK-CROSSES OF THE TWO HYBRID (*RS*) FEMALES WITH THE PARENT RESISTANT (*R*) AND SUSCEPTIBLE (*S*) MALES
The actual numbers of mosquitoes involved are given in brackets

Parents	*R*♀ × *S*♂				*R*♂ × *S*♀			
Back-cross	*RS*♀ × *S*♂		*RS*♀ × *R*♂		*RS*♀ × *S*♂		*RS*♀ × *R*♂	
Back-cross offspring	Susceptible	Hybrid	Resistant	Hybrid	Susceptible	Hybrid	Resistant	Hybrid
Males	57 (384)	43 (295)	48 (167)	52 (181)	49 (195)	51 (202)	45 (133)	55 (161)
Females	49 (364)	51 (380)	51 (241)	49 (23[illegible])	56 (194)	44 (150)	49 (195)	51 (207)

were crossed with the resistant male parent. Subsequent offspring were exposed to the dosage killing hybrids and the following proportions obtained :

	Hybrids	Resistants
Males	53 per cent (86)	47 per cent (75)
Females	41 per cent (119)	59 per cent (170)

The surviving males and females from this latter exposure, on being crossed with the parent resistant strain, yielded pure resistant strains again.

In addition to the selection of this resistant strain from the back-cross of the hybrid with the susceptible parent, the offspring of this back-cross were shown to be composed of hybrids and susceptibles only, by exposing them to the dosage which kills hybrids. Such exposure resulted in 100 per cent kill. Similarly, exposure of the offspring of the back-cross of the hybrid with the resistant parent to a dosage which kills susceptibles only resulted in no kill at all.

This finding of a monofactorial inheritance of resistance indicates the necessity for a change in the method of detecting resistance in the field. The present method of comparing the *LD*50 of a particular insecticide in an insect population where resistance is suspected with that in a population where the insecticide has never been used may show only a small difference, in some cases not even statistically significant, depending on the proportions of the three groups (susceptibles, hybrids and resistants) in the population examined. Thus, in Western Sokoto, from where these dieldrin-resistant *A. gambiae* originated, the degree of resistance was recorded[3] as only eight times in 1955. The use of separating or discriminating dosages would have enabled a selection of the pure resistant strain, which is in fact some 800 times as resistant as the susceptible. It is suggested, therefore, that instead of a comparison of *LD*50 in the two populations, the minimum *LD*100 be established in the susceptible population, and the suspected population exposed to this dosage. Survivors, if any, can then be reared and their offspring exposed to higher dosages to select the resistant strain.

Alternatively, an accurate dosage/mortality regression line can be made in the suspected area, using a large number of dosages of the insecticide. If resistance is present, it will be shown by two steps in the line where increase in dosage produces no change in kill. These are the discriminating dosages between susceptibles and hybrids and between hybrids and resistants.

Copper Deficiency in Sitka Spruce Seedlings

FOR several years a symptom referred to as 'needle tip-burn'[1–3] has been observed in Sitka spruce seedlings at the Forestry Commission Research Nursery, Sugar Hill, near Wareham, Dorset. The nursery, which occupies land formerly covered by *Calluna* and scrub pine, is on a highly leached sandy soil over Bagshot Sands (Lower Eocene), with a humus and iron pan at varying depth. To break the pan, most parts of the nursery have been subsoiled in recent years.

'Needle tip-burn' usually appears during dry hot spells in midsummer, the damage being confined to the more vigorously growing seedlings. The tips of the upper needles shrivel and turn straw colour. There is a distinct break between the normal green lower part of the needle and the withered upper part, and in many cases a ring-like structure separates the healthy from the shrunken portion. The symptom is often accompanied by a spiral twist of the upper needles. If dry hot weather persists for a long period, plants rarely recover and the growing point dies. Later in the summer the upper needles turn brown or black and carry infections of *Botrytis* or other fungi. If the hot spell lasts for only a short time and is followed by moist conditions most of the new needles that emerge are free from tip-burn, and all that is left to indicate the earlier attack is a ring of damaged needles lower down the stem.

Whereas 'needle tip-burn' is common on seedlings grown with inorganic fertilizers, damage has only rarely been observed on seed-beds treated with a compost made from hop-waste and chaffed green bracken. In an early experiment in which a variety of composts were compared, only those containing hop-waste prevented tip-burn.

The resemblance of 'needle tip-burn' to 'withered tip disease' in cereals, its mode of occurrence and the incidence of copper deficiency in fruit trees on Bagshot Sands[4–6], suggested that the symptoms in Sitka spruce might also be due to lack of copper. In June 1955, therefore, a foliar spray of copper sulphate was applied to half the plots in an experiment on Sitka spruce seedlings grown with inorganic fertilizers. The spray supplied 0·16 gm. copper per square yard in 300 ml. water, that is, a solution with about 0·05 per cent copper. Five weeks after application the untreated plots were beginning to suffer from tip-burn but the sprayed plots were completely free. Later in the season tip-burn became severe on the no-copper plots ; slight symptoms were, however, visible on the plots treated with copper sulphate. Table 1 shows visual 'scores' for needle damage taken on four different occasions, seedling height in inches at the end of the growing season and the copper content of the whole seedling.

The copper sulphate spray increased seedling height by nearly 50 per cent and copper content by 40 per cent ; but it did not completely remove the symptoms, and higher rates of application are therefore being tested in 1956.

In seed-bed experiments laid down in 1951 at Sugar Hill Nursery, Wareham, and at Kennington Nursery, near Oxford, a standard inorganic fertilizer has been compared each year with a compost made from bracken and hop-waste. In 1955 the fertilizer plots at Wareham showed considerable tip-burn but the compost plots were free. No tip-burn symptoms have ever been observed on either treatment at Kennington, a sandy loam over Jurassic Calcareous

Table 1. SITKA SPRUCE SEEDLINGS AT WAREHAM NURSERY, 1955

	Visual 'scores' for 'needle tip-burn'				Mean height (in.)	Cu in dry matter of seedling (p.p.m.)
	Aug. 4	Aug. 11	Aug. 23	Oct. 6		
Untreated	2·4	3·4	4·4	5·1	1·9	2·3
Copper spray	0·0*	0·0	1·0	2·2	2·8	4·2

*0·0 means no damage

Table 2. Sitka Spruce Seedlings 1955

	Visual 'scores' for 'needle tip-burn'		Cu in dry matter of seedling (p.p.m.)	
	Wareham	Kennington	Wareham	Kennington
Fertilizer	3	0	2·8	10·8
Compost	0	0	7·0	10·4

(0 = no damage)

Grit. Visual 'scores' and copper contents of the crops are shown for both centres in Table 2.

The results of analysis of several batches of bracken and hop-waste (Table 3) show that, whereas the copper content of bracken was around 10 parts per million, the value for hop-waste approached the 1,000 parts per million level. A sample of unextracted hops was found to contain only 95 parts per million, so that a large fraction of the copper in the hop-waste presumably came from sources at the brewery such as copper boilers used in the extraction of the hops.

Table 3. Copper Content of Hops, Bracken and Bracken Hop-waste Compost

	Cu in dry matter (p.p.m.) Range	Mean
Hops	—	95
Hop-waste ('spent hops')	865–970	910
Bracken	11–13	12
Bracken hop-waste compost	340–465	365

The absence of tip-burn on the Sitka spruce seedlings grown with bracken hop-waste compost can therefore be ascribed to the high copper content of the compost.

The experiments discussed in this communication are part of an investigation carried out in intimate collaboration with the Research Branch of the Forestry Commission.

αε-Diaminopimelic Acid in the Peptide Moiety of the Cell Wall Polysaccharide of *Bacillus anthracis*

Bacillus anthracis contains a polysaccharide which appears to be part of the cell wall[1]. Ivanovics[2] first isolated the polysaccharide which contained galactose 34 per cent, glucosamine 34 per cent, nitrogen 4·2 per cent and α-carboxyl amino-nitrogen 0·8 per cent. Strange and Belton[3] obtained from culture filtrates of *B. anthracis* a polysaccharide which contained galactose 39–43 per cent, glucosamine 34 per cent, nitrogen 3·9 per cent and α-carboxyl amino-nitrogen 1·26 per cent. The differences between the total nitrogen and glucosamine nitrogen values together with the figures for α-carboxyl amino-nitrogen in these preparations indicated the presence of 5–10 per cent of amino-acid residues. Smith and Zwartouw[4] obtained a polysaccharide from *B. anthracis* grown *in vivo*. It contained galactose 38–43 per cent, glucosamine 38–44 per cent, nitrogen 4·0 per cent and α-carboxyl amino-nitrogen 0·3 per cent. Since this preparation satisfied a number of rigorous tests for homogeneity it was concluded that a small peptide moiety (2–3 per cent) was firmly attached to the polysaccharide. We are concerned here with the constitution of this peptide moiety.

The amino-acids detected in the polysaccharide preparations were alanine, aspartic acid, glutamic acid and glycine[3,4]. This restricted amino-acid content was peculiar and only recently recognized as resembling that of the peptides containing αε-diaminopimelic acid and an unidentified amino-sugar, which form part of the walls of some bacteria[5] and spores[6]. Two samples of the polysaccharide as isolated from *B. anthracis*[3,4] have therefore been re-examined with the object of detecting the presence of small quantities of αε-diaminopimelic acid and unidentified amino-sugar; both compounds were found.

(1) *Detection of αε-diaminopimelic acid.* Samples (25 mgm.) were hydrolysed (6 *N* hydrochloric acid, 100°, 16 hr.) and the hydrolysate after evaporation was run as a band on a paper chromatogram using collidine/lutidine/water as solvent and synthetic αε-diaminopimelic acid as standard. After examination in ultra-violet light, strips of paper in positions equivalent to the standard were eluted with water. Portions of the evaporated eluates (equivalent to at least 6 mgm. of the original polysaccharide) were compared with synthetic αε-diaminopimelic acid on chromatograms using the solvent of Rhuland, Work, Denham and Hoare[7]. αε-Diaminopimelic acid (meso and/or DD isomers) was found in both samples of polysaccharide and its approximate concentration was 0·1–0·2 per cent.

(2) *Detection of the unidentified hexosamine of Strange and Powell*[6]. Samples (20–30 mgm.) were hydrolysed (6 *N* hydrochloric acid, 3 hr., 100°) and the hydrolysate evaporated, redissolved, neutralized with *IR*-4*B*(OH) and filtered. Almost all the glucosamine was removed from the filtrates by treating them for 20 min. with *IR*-120 (2 gm.) which had been buffered at *p*H 6·05 [8]. After removal of the resin, the filtrates were analysed for hexosamine by the Elson and Morgan method and contained 0·6–1·0 per cent calculated on the weight of polysaccharide taken. In this analysis, the absorption maximum of the coloured derivatives were near

$$520\ \text{m}\mu \left(\frac{-\log T\ 530}{-\log T\ 520} = 0{\cdot}97 \text{ compared with } 0{\cdot}90\right.$$

for unidentified amino-sugar and 1·05 for glucosamine), indicating that, in addition to the small amount of residual glucosamine, the unidentified amino-sugar was present in the filtrates[8]. This was confirmed by paper chromatography. The evaporated filtrates were chromatographed using tertiary butanol/6 *N* hydrochloric acid/water in the volume ratio 70 : 1 : 29 as ascending solvent (16 hr.) on papers containing glucosamine and unidentified amino-sugar. The dried papers were sprayed with ammoniacal silver nitrate and heated. Both polysaccharide samples formed spots which corresponded with unidentified amino-sugar.

The amounts of αε-diaminopimelic acid and unidentified amino-sugar detected in the polysaccharide of *B. anthracis* indicate that the whole of the peptide moiety of the polysaccharide could be composed of the so-called 'cell wall peptide'. The presence of αε-diaminopimelic acid and unidentified amino-sugar in the polysaccharide suggest that the cell wall of *B. anthracis* consists—in part at least—of a compound of the polysaccharide and the 'cell wall peptide'. In this connexion it is recalled that a preparation from *Bacillus* '*M*' described by Guex-Holzer and Tomcsik[9] contained αε-diaminopimelic acid, unidentified amino-sugar, galactose and glucosamine as well as large quantities of phosphorus, although rigorous tests for homogeneity of the preparation were not described.

A Pasture Response to Sodium Tungstate on a New Zealand Soil

IN an investigation of an apparent superiority of basic slag over superphosphate in stimulating pasture growth on a yellow-grey earth of the Warepa series (Otago Province), slag-treated plots were compared in 1951 with plots receiving superphosphate, (1) alone, (2) plus ⅛ oz. sodium molybdate, (3) plus 2½ oz. molybdate and (4) plus 1 lb. ammonium metavanadate per acre. Molybdenum application at both rates markedly increased pasture production, notably through the clovers, while vanadium had no effect. In September 1953 sodium tungstate (molybdenum content < 0·1 p.p.m.) was applied over one block of the experiment at 1 lb./acre. The superphosphate plot with no applied molybdenum and that with vanadium responded greatly, particularly in white clover growth, that with ⅛ oz. sodium molybdate responded slightly, while the plot treated with the heavier rate of sodium molybdate showed no additional effect from tungsten[1]. The implication was that tungsten could assume the role of molybdenum, presumably in nitrogen fixation by *Rhizobia*. A replicated trial studying the interactions of molybdenum, tungsten and vanadium, applied in proportion to their atomic weights (sodium molybdate 2½ oz./acre), has now been run on the same soil type. The trial was laid down on March 24, 1955. In the five yield cuts so far taken covering the period August 10, 1955–February 28, 1956, vanadium has had no influence either by itself or in conjunction with molybdenum or tungsten. It can therefore be disregarded in considering the molybdenum × tungsten interaction. Results are exemplified by data from the second yield cut in the tungsten × molybdenum interaction table (Table 1).

Table 1. YIELDS OF DRY MATTER LB./ACRE, OCTOBER 13–NOVEMBER 10, 1955

	No tungsten	Tungsten	Mean
No molybdenum	770	940	850
Molybdenum	1,120	1,070	1,100
Mean	940	1,010	

Sig. diff.: 5 per cent, 100; 1 per cent, 130.
Molybdenum × tungsten interaction significant at 1 per cent level.

There is a significant response to tungsten only in the absence of molybdenum. In the presence of tungsten in the above cut, response to molybdenum just achieves significance at the 1 per cent level. Two further yield cuts gave similar results while the interaction in the first and fourth was not significant. Over the whole period of 6½ months both molybdenum alone and molybdenum plus tungsten gave a 27 per cent increase in dry matter production; tungsten in the absence of molybdenum a 16 per cent increase.

In an accompanying trial, rates of sodium tungstate at 1, 2, 4, 8 and 16 oz. per acre were compared. By the third cut all rates were giving significant increases in yield of pasture, amounts above 4 oz./acre conferring no extra advantage. In the fifth cut yields were recorded increasing up to, but not beyond, the 8-oz. level.

Tungsten is probably acting as a substitute for molybdenum in its role in nitrogen fixation, but less effectively. Heavier applications, at least initially, have shown no advantage; if tungstate merely freed soil molybdate held in an unavailable form one would have expected the reverse to hold. Moreover, the anion exchange effect of the far heavier basal application of phosphate (2 × 3 cwt. superphosphate) would have tended to mask any such action.

Bortels has directed attention to tungsten and vanadium having an effect similar to, but much smaller than, molybdenum in stimulating nitrogen fixation by blue-green algæ of the genera *Anabaena* and *Nostoc*[2]. In Bortels's studies with *Azotobacter* spp. and *Clostridium butyricum*[3] tungsten increased effects of vanadium and, to some extent, of sub-optimal amounts of molybdenum, the former observation prompting the trial of tungsten in the present instance.

Phosphine as a Phosphatic Fertilizer

SINCE ammonia gas has been highly satisfactory as a nitrogenous fertilizer it is surprising that there is no record of any experimental work on its analogue phosphine as a source of plant phosphorus. Phosphine has many obvious disadvantages; but the fact that it is more than ten times as concentrated as superphosphate, our standard arable phosphatic fertilizer, surely merits some consideration. Commercial handling may not present any more serious problems than did some of the modern phosphorus insecticides.

A preliminary glasshouse experiment on radishes and wheat showed that phosphine was not toxic to germination or growth at normal dressings and only at a rate equivalent to 18 cwt. per acre of superphosphate was some leaf discoloration noticed. Soil retention of the compound was nothing like so efficient as with ammonia ; but at all normal dressings no loss to the atmosphere should be experienced.

In a 5 × 5 latin square glasshouse experiment with radishes where superphosphate was applied at 0, 1½ and 3 cwt. per acre and phosphine at the same levels of phosphorus there was no significant difference in the response of either total fresh matter or dry matter between the two sources of phosphorus. At the higher levels, however, the uptake of phosphorus from phosphine was very highly significantly ($P < 0{\cdot}001$) better than and almost double that from superphosphate. This suggests that soil fixation may be lower with phosphine than superphosphate, and it is proposed to investigate this matter further.

Occurrence of Peroxidase in Tension Wood of Angiosperms

Tension wood in angiosperms can be readily induced by bending stems and branches from their normal orientation, when it develops usually on the upper side of the stem or branch, in the form of a dense band (compact type), or in groups of fibres or isolated fibres scattered among the normal fibres of the tissue (diffuse type). Tension wood fibres are characterized by the fact that the fibre walls are partially or wholly unlignified[1]. The formation of tension wood thus involves a differential lignification of the xylem on the two sides of the stem or branch.

In investigations into the nature of lignification, the work of Freudenberg *et al.*[2,3], and of Siegel[4] has shown that the mechanism most probably involves oxidation of a phenyl propane type precursor by an oxidase, phenoloxidase or peroxidase. In conifers the seasonal variation in peroxidase in the zone of differentiating xylem was studied by Manskaya[5] and found to be inversely related to the coniferin content of the tissue. From this it was concluded that coniferin may form a substrate for the peroxidase, during lignification.

To examine the nature of the asymmetry of lignification in stems forming tension wood, the peroxidase distribution was studied. The method of McJunkin[6] using benzidine and hydrogen peroxide was employed to determine the peroxidase distribution. In the zone of tissue including the cambium no peripheral variation in the amount of peroxidase in stems of *Eucalyptus goniocalyx* and *Eucalyptus cladocalyx* could be seen. However, in the mature tension wood intense peroxidase activity was observed in the unlignified region of the fibre cell walls. This is illustrated in a band of tension wood of *E. goniocalyx*, shown in Fig. 1, where the area of peroxidase activity appears dark. Similar activity was observed in the fibre walls of tension wood of the diffuse type. The peroxidase reaction was not obtained if the sections were first treated with cyanide. Addition of hydrogen peroxide to the tissue did not result in the formation of any lignin-like substances. It thus appears that the failure of tension wood to lignify may result from the differential formation of the lignin precursor on the two sides of the stem. Alternatively the change in cell metabolism resulting in the formation of highly crystalline cellulose in the cell wall may fail to provide sites to which the lignin synthesized can link, since in lignified cells lignin appears to be associated with the non-cellulosic fraction of the cell wall[7].

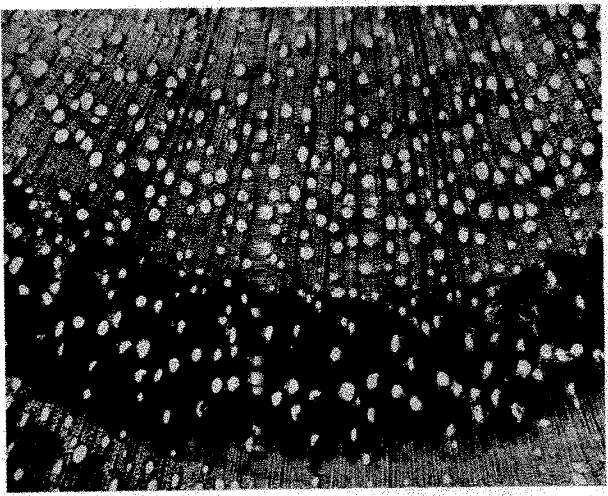

Fig. 1. *Eucalyptus goniocalyx.* A transverse section of a young stem containing a compact band of tension wood, after staining for peroxidase. (× 90)

Further investigations are in progress.

Mating in Scorpions

The courtship dance of the scorpion has been observed and recorded repeatedly since 1810 when Maccary[1] first described it. The actual conclusion of this elaborate behaviour pattern has, however, only been surmised from circumstantial evidence. For example, both Fabre[2] and Brongniart and Gaubert[3] report that scorpions were surprised beneath stones "accouplés, ventre à ventre". Vachon[4] writes as follows : "the conclusion of these nuptial dances I have not observed but anatomical investigation bears out the statement of early writers ; the male fertilizes the female directly in a true copulation. . . .

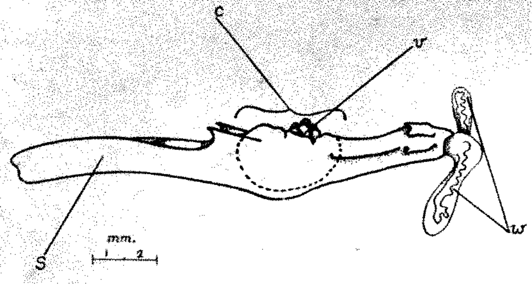

Fig. 1

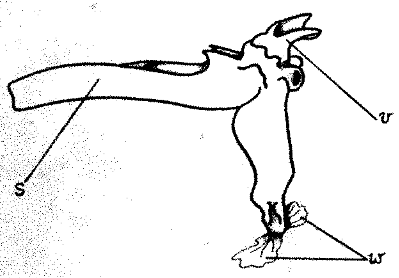

Fig. 2

In the course of this act, the male protrudes certain special organs to form a temporary penis, with which he inserts the sperm and finally places in position a vaginal plug—a kind of post-nuptial hymen".

Now it is known[5] that pseudoscorpions go through a courtship which is in many respects like that of the scorpions. During this, the male deposits on the ground a spermatophore from which the female removes the sperm mass. Lawrence[6] says, "it may be surmised that the mating act in scorpions and pedipalpi . . . follows the same general lines as that of the pseudoscorpions".

In the scorpion, *Opisthophthalmus latimanus typicus* C. Koch, the courtship has been observed repeatedly and will be described in detail elsewhere. Suffice it to say that the classical "arbre droit" is either absent or only fleetingly present; the "promenade à deux" occurs but does not usually last longer than an hour. During this latter pattern the male holds the cheliceræ of the female and not, as has been reported for other scorpions, her pedipalps. The promenade is executed over a very limited area; when the animals are performing on rough ground the male clears the soil particles from the space in which the pair are dancing but if the ground is smooth he does not show this behaviour.

In two cases recently observed in this laboratory the courtship continued to the consummatory act and the fertilization of the scorpion was witnessed. Shortly after the beginning of the promenade the genital operculum of the female was seen to be open; a little later that of the male opened as the extrusion of a spermatophore began. During the extrusion the pair continued to move backwards and forwards in the manner typical of the "promenade à deux", but with more limited excursions. As soon as the spermatophore (Fig. 1) was clear of the genital aperture of the male, he moved back slightly so that it lay free on the ground beneath him. After a few seconds he began to jerk the female violently, drawing her over the spermatophore and half-lifting her at the same time. This pattern contains the "back and forward" movement characteristic of the promenade, but the female was gradually drawn forward to a position over the spermatophore. She appeared to drop down suddenly over the capsule of the spermatophore (Fig. 1, *c*) and almost immediately rose again with the opened valves (Figs. 1 and 2, *v*) inserted into her genital aperture. The wings (*w*) were seen to be holding one end of the spermatophore firmly to the ground while the stalk (*s*) was bent through a right angle and pointed towards the male.

The two animals stood immobile for about five minutes in this attitude, the male holding the female, who held the valves of the spermatophore capsule inside her genital aperture.

The male then began to make slight retreating movements which the female appeared to resist. Suddenly the male released the cheliceræ of his partner and clutched at her with his claws, spreading his pedipalps widely. He brought his tail over and thrust his sting at her back though he did not actually insert it into her body. She responded by moving off backwards so that she was torn free of the empty spermatophore, which was left sticking to the ground (Fig. 2). The male drove her about 25 cm. from the spermatophore; she made no attempt to sting him but clutched rather feebly at him with wide-spread pedipalps. The male then turned round, rushed away and took cover.

The female moved about slowly for 30 sec. or so with her genital aperture pressed to the ground as if searching for something. When she passed over the spermatophore she ignored it. She made chewing movements with alternate cheliceræ, then suddenly appeared to lose interest in her 'search' and hurried off to cover.

Within an hour the male was observed to react favourably to another female; but when placed with the female that he had just fertilized, the pair fought violently until he retreated.

Thus *O. latimanus* shows no true copulation but a fertilization mechanism similar to that found in the pseudoscorpions—a fact in keeping with the general similarity of their genital structures, spermatophores and courtship. Furthermore, the mechanism provides a possible explanation of the "promenade à deux" of the scorpion. If the behaviour of *O. latimanus* is general for these animals, the main movement of the fertilization process is that by which the male jerks the female back and forth until she is in the correct position over the spermatophore, which she then picks up. The promenade would appear to be a prolonged intention movement of this "picking-up-the-spermatophore".

These observations were made during the tenure of a bursary awarded by the South African Council for Scientific and Industrial Research, to whom my thanks are due.

'Taming' of the Wild Norway Rat by Rhinencephalic Lesions

THE common Norway rat is a wild, fierce, aggressive animal which fights with other rats or other animals, large or small, at apparently slight provocation. When captured and brought into the laboratory such rats show no diminution of their aggressive tendencies even after months or years of the comparative safety and ease of laboratory life. They escape at the slightest opportunity and are difficult to recapture. They must always be handled carefully and with heavy gloves to avoid serious injury.

Several years ago, while working in Baltimore, I initiated a study of the effects of destruction of the amygdaloid nuclei in the brains of wild and domesticated Norway rats. It was thought at the time that observations made upon two strains of the same species—one wild, fierce and intractable ; the other docile, friendly and easily handled—might throw some light upon the often disputed effects of such lesions upon emotional and sexual behaviour in animals.

As a result of some incidental observations on endocrine function in some of the wild rats[1], attention was diverted and only a few domesticated rats were studied. Recently, the behaviour studies on wild rats have been repeated in a different laboratory (see present address), and it now seems worthwhile to report the striking changes in the behaviour of wild rats following the placement of lesions in the amygdaloid complex. Confirmation of the original observations has also been obtained elsewhere[2].

To date, 42 wild rats with bilateral amygdaloid lesions have been studied. Control observations have been provided by : (1) both pre- and post-operative study of the behaviour of the operated rats ; (2) twelve rats which were operated unilaterally in two stages with an intervening period of several weeks or months ; (3) rats which were captured at the same time as the operated animals and were kept in the laboratory under identical conditions during the life-time of the operated animals ; (4) sham operated rats.

None of the control animals has ever shown any observable change in behaviour.

On the other hand, either surgical or electrolytic intervention bilaterally in the area of the amygdala has inevitably produced 'tameness' in wild rats. Although eleven rats reverted to their pre-operative aggressiveness after a few days or weeks, thirty-one remained 'tame' for long periods (up to three years).

The most striking change in the behaviour of these rats is that, immediately following the operation, they no longer bite the experimenter. As soon as they recover from the anæsthetic (ether) they can be handled without gloves and without fear of attack. Large (500–600 gm.) operated wild rats may be carried about for hours in the laboratory coat pocket without incident. They do not bite and they do not attempt to escape. Yet, they remain as alert and as active as before operation.

In addition to their behaviour with respect to handling, these rats have been observed when placed with other rats and with mice.

When white mice are introduced into a cage with normal wild rats, the mice are usually killed within a few seconds. On the other hand, wild rats with bilateral amygdaloid lesions rarely, if ever, molest the mice. In fact, they often exhibit a maternal-like grooming behaviour. This phase of the problem has been extensively studied and is reported elsewhere by Karli[2].

When wild rats are paired in the 'fighting chamber' designed by Richter[3], they fight when given mild electrical shocks on their feet. Such fights are vicious and often end in death for one of the pair. Following operation, these animals rarely, if ever, attack their partner. Their post-operative behaviour is indistinguishable from that of domesticated rats under the same conditions.

The brains of seven wild rats which remained 'tame' for three months or more have been sectioned ; but none has been completely reconstructed as yet. Gross inspection and microscopical study of the sections reveal that in no brain was the amygdala completely destroyed. In all cases damage was restricted to rhinencephalic structures.

Although the precise extent of the lesion necessary to produce these changes in behaviour is as yet unknown, there seems to be little doubt that damage to the brain in the area of the amygdala produces an immediate, and in most cases permanent, loss of fierceness and aggressiveness in wild Norway rats. The mechanisms involved remain completely unknown.

Heat Regulation of MaSarwa (Bushmen)

BUSHMEN in their natural state fulfil two important criteria for acclimatization to heat[1]. They probably are unique among indigenous peoples in this regard. In the first place, they are exposed to high temperatures and fairly intense radiation. Globe thermometer readings of 140° F. in the sun and 104° F. in the shade were recorded on our excursion into the Kalahari Desert. Secondly, these men are nomadic hunters, and, in tracking down and pursuing wild game, they exercise actively in these temperatures.

Four 'wild' Bushmen volunteered and were studied near Tsetsing, some 250 miles north-west of Molepolole in the Kalahari, Bechuanaland Protectorate. The experiments were conducted in a tent to eliminate the effects of direct solar radiation and of possible variations in wind velocity. In all other respects except one the routine followed closely upon that used for developing the Predicted 4-Hourly Sweat-Rate Index[2]. The exception is that mouth and not rectal temperatures were measured as the Bushmen refused the latter. By adding 1·2° F. ± 0·6° F., mouth temperature can be converted to rectal temperature with reasonable accuracy[3].

The small size of the Bush people compared with Europeans is made clear in Table 1. The resting metabolic rate was close to that of the Singapore naval rating[4] ; but the metabolic cost of work was closer to that of the Queen's Square subjects. Hence the amount of heat to be dissipated per unit surface area by Bushmen is similar to that of Europeans. Under conditions of mild heat stress, namely, 88° F. air temperature, 72° F. wet bulb temperature and globe temperature of 92° F., which has a Sweat-Rate

Table 1

Place	No.	Height (cm.)	Weight (kgm.)	Surface area (m.²)	Rest		Work	
					O_2/min.	Cal./m.²/hr.	O_2/min.	Cal./m.²/hr.
Singapore	12	172·1	64·3	1·76	0·283	46·82	0·951	164·01
London	16	171·0	66·0	1·77	—	54·0	—	180·0
Kalahari	4	158·4	45·5	1·44	0·220	44·21	0·897 (7 mea)	183·6 (7 mea)

Table 2

Subject	No.	Initial temperature (° F.)	Highest working temperature (° F.)	Final temperature (° F.)	Sweat-rate	
					Actual	Per m.²
Europeans (acclimatized)		98·7	—	99·2	1·2	0·678
MaSarwa	4	98·4	98·7	98·4	0·890	0·618

Index rating of 1·2 l./4 hr., Bushmen regulate successfully against heat, judging by the oral temperature responses (Table 2). The actual sweat-rate is less than that of acclimatized Europeans; but is very similar when corrected to unit surface area. Using these two criteria Bushmen in their natural state are as well adapted to this degree of heat stress as are acclimatized Europeans. More severe heat stress might bring out differences such as were observed recently between Europeans and Bantu peoples[5]. It was not possible, however, to extend the studies on this excursion.

We gratefully acknowledge a grant from the South African Council for Scientific and Industrial Research, Pretoria, which enabled us to make this study. Allan Cuzen and P. Stubbs, of the Witwatersrand Native Labour Association, gave invaluable aid.

Control of Sex Ratio in Mammals

Weir[1] selected individuals of a heterogeneous strain of mice for high and low blood *p*H and established lines averaging at *p*H 7·42 and *p*H 7·46. The sex ratio of the two lines was found to diverge from 50 : 50 to approximately 40 : 60 and 60 : 40. Acid lines produced an excess of female progeny and alkali lines an excess of males. On reciprocally crossing, Weir found that the whole of the sex ratio divergence was due to the male *p*H; the female *p*H seemed to exert no influence.

It is a matter of great interest to determine: (1) whether Weir's principle may be extended to other mammals; (2) whether blood *p*H changes occurring or induced during ontogeny are reflected in alterations of the sex ratio.

No data which directly relate blood *p*H and sex ratio, apart from Weir's, seem to be available; but in several cases it is possible to infer that the principle is operating.

(1) In man the existence of non-random influences on sex ratio has been inferred from the much-discussed data of Geissler[2]. Hewitt, Webb and Stewart[3] have found an excess of all-male, though not of all-female, sibships in a collection of English families.

That these variations could be partly due to the operation of Weir's principle is suggested by data of Heath[4]. These show a significant tendency on the part of men with a high recovery index to beget an excess of daughters. Generally, 'athletic' men deviate in this direction. While athletic exertion causes a temporary reduction in blood *p*H, it does not seem to be known whether repeated exertion induces the slight permanent lowering which may be required to influence sex ratio. Shock and Hastings[5] found variations between *p*H 7·34 and *p*H 7·45 in human blood. Individuals differed significantly from each other in regard to the acid-base balance of their blood.

(2) In cattle, data of the progeny of bulls used for artificial insemination were recorded at the Southbar Cattle Breeding Station in Scotland between 1947 and 1952. Mr. James Isbister kindly made them available to me for analysis. 37,515 calves from 32 bulls were listed; of these 18,795, that is, 50·100 per cent, were females. No less than 12 bulls deviated significantly from a 1 : 1 ratio, seven of them so far that $P < 0 \cdot 01$. The total heterogeneity was measured by $\chi^2_{[31]} = 123 \cdot 41$; $P \ll 0 \cdot 001$. This indicated that a major source of sex ratio control must lie on the paternal side. The performance of 23 bulls could be broken down into annual components; most were fairly stable, but 3 of them changed their sex ratios significantly. Again, the essential data on blood *p*H are not available, but the operation of Weir's principle should be suspected.

(3) In rats, data of Moore and Price[6] can be analysed to show that at 7,500 ft. and 9,600 ft. there was a highly significant excess of females in litters conceived after the animals had been 60 days at these stations (male, 133 : female, 180. $\chi^2 = 7 \cdot 05$; $P < 0 \cdot 01$). At 14,260 ft. there was a significant excess of males in litters conceived after the parents had been 30 days at the station (male, 33 : female, 17. $\chi^2 = 5 \cdot 12$; $P < 0 \cdot 05$). The latter result is expected, in that high altitude is supposed to induce alkalosis. The results at less-extreme altitudes would indicate acidosis, if Weir's principle is operating. In any event, we have here strong deviations in sex ratio under conditions where disequilibrium in blood *p*H should be expected.

Monge[7,8] describes marked changes in serum *p*H during chronic mountain sickness in man. He compares the physiological condition of men acclimatized to high altitude with that of athletes. In sheep at high altitude he claims that failure to conceive is due to widespread occurrence of azoospermia; some rams show wide variations in seminal *p*H "which indicates that the *p*H regulating system fails at high altitude". By selecting rams for normal seminal *p*H and sperm-motility the fertility of the flocks was improved.

(4) In mice, Bittner[9] found highly significant deficiencies of males in the progenies of inbred parents reared on a 'rolled oats' diet; these deviations remained significant even when the comparison was limited to 'undepleted' litters. Diet is clearly a factor which might affect blood *p*H.

Despite the absence of direct experimentation, (1), (2) and (3) above point to the extension of Weir's principle to mammals other than mice. (1) and (3) also suggest that slight changes in blood *p*H can be induced. From (2) it appears that the conditions influencing sex ratio in some bulls are labile.

A practical system of controlling sex ratio in economically important animals might, then, be set up by: (*a*) selecting sires for the appropriate *p*H tendency; (*b*) altering the *p*H of sires by: (1) administration of drugs; (2) changes in dietary regime; (3) modifications in oxygen tension.

Analyses of the data referred to here will be published elsewhere.

Anharmonicity, Thermal Expansion and Thermal Resistance in a Dielectric Solid

In the limit of high temperatures ($T \gtrsim \Theta$) the thermal resistance of a dielectric solid is roughly proportional to the temperature:

$$W = W_\Theta T/\Theta$$

Two approximate formulæ[1,2] have been proposed recently expressing W_Θ in terms of equilibrium thermodynamic properties of the solid; in both formulæ W_Θ is equal to the product of the square of the coefficient of the thermal expansion and an appropriate dimensional factor derived from other properties of the solid. These formulæ can easily be shown to be essentially equivalent[3], and they are found to agree with the experimental data for many simple solids[1,2,4] within an order of magnitude, although discrepancies within a factor of 3 or 4 are not uncommon.

I wish to point out that such formulæ could only be strictly valid if there were a single parameter describing completely the 'anharmonicity' of the crystal potential, such as the parameter γ introduced by Grüneisen in his theory of thermal expansion. Now in a three-dimensional lattice there is no unique Grüneisen γ, and the quantities γ_j ($= -\mathrm{d}\log\nu_j/\mathrm{d}\log V$) obtained from the frequencies ν_j of normal modes are spread over a range of values[5]. The empirically determined value of γ is usually derived from the thermal expansion observed at 'high' temperatures ($T \sim \Theta$), and this parameter, γ_∞ say, is then the arithmetic mean $\overline{\gamma_j}$.

Let us consider now the special case of a lattice for which this mean vanishes; there do not seem to be any simple real solids for which this is true; but it is easy to derive simple theoretical models having this property. There will then be a negligibly small thermal expansion at the high-temperature limit, and the formulæ will therefore predict no thermal resistance. But actually there will still be anharmonic terms in the crystal potential, and these will give rise to coupling between the normal vibrations and hence in general to a finite thermal resistance. This implies that any formula of this type must break down when γ is sufficiently small; further, that too small a value will then be predicted for the thermal resistance. This is consistent with the observation of Leibfried and Schlömann[1] that approximations made during the derivation of their formula are not valid when γ is small.

Of course, even if the validity of such formulæ could be established for large enough γ there still seems no reason to expect the same factor of proportionality for different crystal structures and different types of atomic or molecular binding; this is borne out by the fairly wide variation of this factor observed experimentally even in substances of high γ values. However, the effect we have been considering may possibly be apparent in substances of low γ. The lowest γ values observed in simple dielectric crystals are those of the elements carbon (diamond), germanium and silicon, all with crystals of diamond structure: the formulæ predict about four times too small a thermal resistivity for diamond[6] ($\gamma \sim 1{\cdot}1$), and even greater disparities have been recently observed in germanium and silicon[7] ($\gamma \sim 0{\cdot}8$). Unfortunately, we have as yet no knowledge of the change of individual frequencies with volume in these elements; while it is unlikely that a spread of γ_j values could account for the whole of the discrepancy, it may be a relevant factor.

Location of Free Electrons in Porphin Ring Complexes

Several molecules containing a porphin ring, of similar central structures, possess intermediate states when undergoing oxidation, and there has been considerable speculation on the actual nature of these transient compounds[1,2]. Most interest has probably been centred on the oxidation of hæmoglobin derivatives, and the action of hydrogen peroxide, potassium periodate and other oxidizing agents has

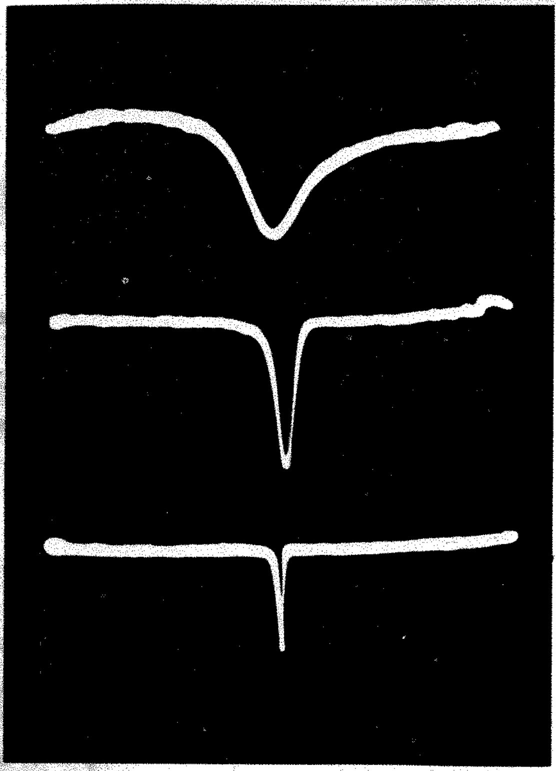

Fig. 1. Absorption lines observed from oxidation intermediates. Top, met-hæmoglobin treated with hydrogen peroxide; centre, metal-free tetra-phenyl-porphin treated with ceric oxalate; bottom, stable free radical diphenyl-picryl hydrazyl. All photographs were taken with the same field sweep

been studied in detail by George and Irvine[2]. The two possible structures for the oxidation state of the met-hæmoglobins are: (1) a radical species formed by hydrogen atom removal from some position in the conjugated ring system, or (2) a change in the valency of the central iron atom. Although several different chemical reactions were studied it was not possible to prove conclusively which of the two structures was actually present.

We have now investigated this oxidation reaction for both hæmoglobin and myoglobin by electron resonance methods, and the results show that a radical species is in fact formed with very little interaction between the unpaired electron and the central iron atom. The spectra observed can also be compared with those obtained[3] from the intermediate states formed during the oxidation of tetra-phenyl-porphin and phthalocyanine derivatives. It would appear that the orbits of the free electrons are very similar in all three cases, and embrace a considerable portion of the conjugated ring structure.

The great advantage of electron resonance techniques in such studies as these is that absorption from the unpaired electrons of the intermediate state can be observed independently of the initial and final products, and their coupling to the central metal and other atoms can be calculated from the g-value and width of the absorption line. The concentrated solution of the acid–met-hæmoglobin or myoglobin was placed in a small cup on the bottom of an H_{111} cavity[4], the oxidizing agent added and, after tuning, the whole resonator was quickly cooled in liquid air. It is possible in this way, by varying the time between addition of oxidizing agent and cooling, to study the rate of formation and decay of the intermediates. Most of the measurements were carried out at 20° K.; but the absorption lines were found to have the same width at 90° K., showing that there was no noticeable spin-lattice interaction present. Identical spectra were also observed at the two microwave frequencies employed, 25,000 Mc./s. and 36,000 Mc./s.

The absorption lines obtained from oxidized hæmoglobin and myoglobin both had a width of 25 gauss and a g-value of $2{\cdot}003 \pm 0{\cdot}001$, and a typical oscilloscope trace is shown at the top of Fig. 1. The same absorption was obtained with potassium periodate as with hydrogen peroxide, and the proximity of the g-value to that of a free electron (2·0023) is definite evidence that the oxidation state is one containing an unpaired electron mobile in the conjugated ring structure. A very similar absorption line is observed from the intermediate oxidation states of both metal-free tetra-phenyl-porphin and metal-free phthalocyanine[3]. These also have a g-value of $2{\cdot}0025 \pm 0{\cdot}0005$, with a somewhat narrower width of 9 gauss, and an example is shown in the middle curve of Fig. 1. The bottom absorption curve is that from the stable free radical diphenyl-picryl hydrazyl, with a width of 3 gauss, and acts as a comparison for the other two. The difference in width between the absorptions of the hæmoglobins and simpler porphins is probably due to exchange effects in the latter, which are absent in the hæmoglobins owing to the very large molecular size.

No hyperfine structure has been observed on any of the spectra obtained from the porphin intermediates, showing that the orbit of the unpaired electron is not confined near the nitrogens in the centre of the ring, but probably includes most of the carbon atoms. Further evidence for the mobility of the electrons in the porphin ring is also found from the hyperfine pattern observed in chlorinated tetraphenyl copper porphin[5], where an orbit embracing the π-bonds round the ring is postulated.

It is hoped that slightly more refined techniques will allow detailed rate studies on such chemical reactions as these; but the present measurements provide conclusive evidence on the nature of the oxidation states.

Path of the Trigatron Spark

In a recent investigation[1] into the characteristics of the trigatron[2] spark gap, an interesting effect was observed in connexion with the path taken by the spark discharge between the spherical electrodes. Several hundred discharges were observed and each spark appeared to consist of two parts. The first was a straight part along the axis of the gap and reaching from one electrode to a distance of 10–50 per cent of the gap-length. The remainder was of the familiar tortuous nature of a spark discharge. The

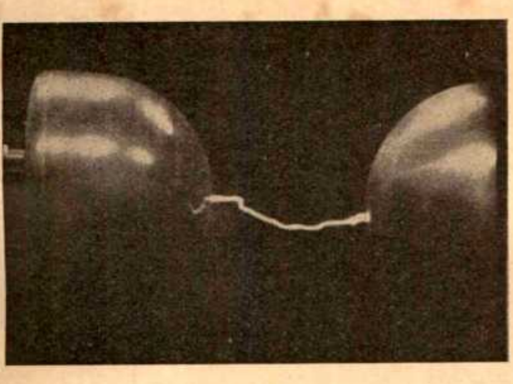

Fig. 1. Photograph of the spark channel in the trigatron gap. Left-hand electrode earthed; negative voltage on right-hand electrode

discharges were photographed from two directions at right angles, using mirrors and using the camera shutter in conjunction with a relay to trigger the spark. The effect occurred with regularity and was quite definite. It was found that the straight part of the spark was always that part adjacent to the anode, whatever the polarity of the high-voltage electrode. A typical photograph illustrating the effect is shown in Fig. 1, where the straight part of the spark is 20 per cent of the total gap-length.

Experimental evidence[1] supports the view that a streamer mechanism is operative in the breakdown of the trigatron gap, and a possible explanation of the effect described above is that breakdown depends on the propagation of a negative streamer, that is, from cathode to anode. When this streamer approaches the anode a positive streamer is initiated at the anode and comes out to meet the negative streamer. The streamers meet at a point in the mid-gap region, giving a change in direction of the spark path at this point. The theory would explain the straight nature of that part of the spark near the anode, since the negative streamer would constitute a conducting path; at the instant propagation of the positive streamer begins the system would thus be approximately equivalent to a very high over-voltage on a point-plane gap, and experimental observations with high over-voltages on point-plane gaps show that straight spark paths do in fact occur. Similar theories concerning change in direction of spark paths have also been given in connexion with lightning discharges, in which it is suggested that positive streamers might grow from the ground to meet the descending negative leader stroke.

A possible alternative explanation of the sudden change in direction of the spark path is that this path is modified by the presence of space charge. The spark tends to pass along the outside of the space charge rather than straight through the centre of the space charge region, where more uniform field conditions may prevail. A similar suggestion has been put forward by Howell[3] to explain the behaviour of the spark path in point-plane gaps.

Enhancement of Ultra-violet Absorption of L-Ascorbic Acid in the Presence of D-Sorbitol

DURING analytical work upon certain pharmaceutical preparations of L-ascorbic acid an unusual enhancement of its ultra-violet absorption was repeatedly observed; namely, ascorbic acid in presence of various concentrations of D-sorbitol shows a considerable increase of its characteristic absorption peak both in neutral aqueous solution (*p*H 6·0) at 265 mμ and in acidic solution (*p*H 2·0) at 245 mμ.

The maxima do not shift to shorter or longer wave-lengths but the absorption curve as a whole simply behaves as if higher than actual amounts of vitamin C had been present in the solution.

Another interesting feature is the difference between the enhancement in neutral and acidic medium, which is in the former far more pronounced. This recalls a similar observation of ultra-violet absorption in irradiated solution of sugars[1]; but in our case the pure sorbitol solutions show practically no ultra-violet absorption at the concentrations examined. D-Sorbitol at *p*H 1–7 and in the presence of potassium cyanide has indeed an ultra-violet absorption of very low order which up to 10 per cent solution does not interfere with that of other solutes. The manner in which the ascorbic acid solutions have been prepared is also important; the increase can be observed only when a very concentrated solution of components of sorbitol and ascorbic acid is made at the same time. Successively, the mother solution can be diluted with water, dilute acid or dilute sorbitol until it reaches the desired final concentration and *p*H. (The diluted solution is stabilized with potassium cyanide.) In this case the reading will every time show the increase of absorption. But if, on the contrary, various amounts of pure crystalline sorbitol are added to prepared and stabilized ascorbic acid solution at a definite concentration, which is always 1 mgm. of ascorbic acid for 100 c.c. of solution, no increase will be found and the ultra-violet spectrum will remain within its normal values. There appears to be a correlation between the concentration of sorbitol and increase of absorption. Some of the values are given in Table 1.

Table 1

Conc. of D-sorbitol/100 c.c.	$E^{1\%}_{1\text{cm.}}/265$ mμ; *p*H 5·8	$E^{1\%}_{1\text{cm.}}/245$ mμ; *p*H 2·0
0·000 gm.	630	550
0·001 gm.	870	656
0·015 gm.	916	676
0·075 gm.	895	648
0·750 gm.	880	638
7·500 gm.	800	580

The reading was made on a Beckman spectrophotometer model *DU*. The solutions of ascorbic acid were controlled by potentiometric titration with dinitrophenolindophenol.

As can be seen, a maximum of increase seems to lie where the concentration of sorbitol is of 15 : 1 relation with that of ascorbic acid; but the values are too close one to another to permit the exact determination within the experimental error limits.

Undoubtedly the enhancement in neutral solution is very pronounced and reaches 48 per cent above the normal values ($E^{1\%}_{1\text{ cm.}}/265$ mμ = 620); in acidic solution the increase is also of high order but reaches only 26 per cent ($E^{1\%}_{1\text{ cm.}}/245$ mμ = 550). The absorption tends to decrease as the concentration of sorbitol increases and in acidic solution reaches 7·5 per cent sorbitol—almost the theoretical value. The higher concentrations of sorbitol have absorptions strong enough to begin to prevent exact reading.

It is known from the work of F. J. Bandelin and J. V. Tuschhoff[2], which was also confirmed by our experiments, that sorbitol in higher concentration exerts a marked stabilizing effect upon L-ascorbic acid in aqueous solution. But a similar effect was observed by us also with D-mannitol, which otherwise seems to have no influence on ultra-violet absorption of ascorbic acid. Thus the two effects, protective and enhancing ultra-violet absorption, cannot be readily accumulated and explained as the whole.

No definite theoretical explanation of the above phenomena can be given at present since the facts are relatively new and still under study. Further work will be done to cover other sugar derivatives and enediols at different values of *p*H, time and temperature.

The hypotheses about stabilizing effect on one of the possible forms of ascorbic acid can be tentatively put forward, although the persistence of increased absorption also in acid medium (*p*H $\sim$ 2) is rather difficult to explain, in view of proton migration which takes place at *p*H 4.

Value of the *p*F Scale for Water in an Ecological Study of an Insect living in Soil

EVANS[1] demonstrated that the energy with which the soil holds water could be correlated with the loss of weight of wireworms; the energy-level was suitably expressed by Schofield's[2] *p*F scale. Evans and McL. Guild[3] then demonstrated that the rate of production and size of cocoons of earthworms were determined not by the amount of water present in the soil but by the force with which the water was held. Despite these observations the *p*F scale as a measure of available water for biological processes has scarcely been used in ecological studies of animals that live in soil. Wallace's[4] paper on the effect of hydrostatic pressure deficiency on motility of larvæ of *Heterodera schachtii* Schmidt is the only other similar study that I know.

A number of field and laboratory experiments on *Aphodius howitti* Hope, a cockchafer which inhabits sandy and loamy soils in South Australia, have suggested that oviposition is influenced by the amount of water in the soil but that expressing the results on a water-content basis for a number of soils is unsatisfactory.

The experiments were carried out with a sand and a clay loam, typical of areas in which the species is found. In one experiment beetles were confined to the two soils at various water-content levels and the numbers of eggs laid were recorded. When the results were plotted against water content of soil the numbers of eggs laid in the sand and in the clay loam could be represented by curves which were similar in form but were widely apart and hence could not be compared directly; however, when plotted against the *p*F of the soil water the curves were found to correspond closely (Fig. 1). It therefore appears that the ovipositional response is a function of the force with which the water is held rather than the amount of water present in the soil. The mean number of eggs in a batch did not vary significantly, the larger number of eggs laid in the range of optimum *p*F being due to more beetles laying all their eggs rather than all the beetles laying more eggs.

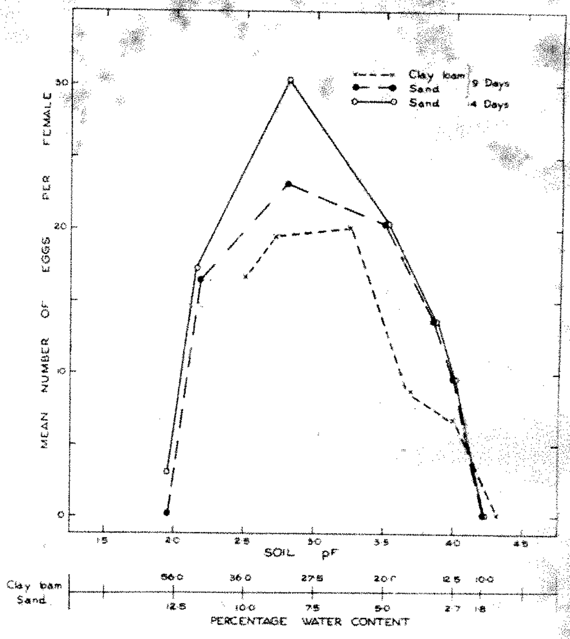

Fig. 1. The numbers of eggs laid by *Aphodius howitti* in relation to *p*F of soil. The water contents of the two soils in relation to *p*F are included for reference

Beetles were then given a choice of four different levels of water content in a series of experiments with both soils. In every case the largest aggregation of beetles and eggs was recorded at a water content corresponding to *p*F 2·8, irrespective of soil type. This *p*F value also proved to be the optimum for survival of the adults.

The consistency with which *p*F 2·8 was recorded as the optimum demonstrates the usefulness of the *p*F scale for comparing the behaviour of adults in different soils.

An investigation of the absorption of water by eggs and their survival in the two soils at various water-content levels showed further that the *p*F scale could be conveniently applied to other stages of the life-cycle. An analysis of variance yielded significant differences between *p*Fs, but no significant difference between soils.

The use of the *p*F scale has led to a better understanding of the effect of water on the types of places in which *Aphodius howitti* lives and its effect on the distribution and abundance of the species in South Australia. It is probable that it could be used to similar advantage in ecological studies of other animals that live in soil.

The details of this work will be published later.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 22

British Society for the History of Science (in the Lecture Theatre of the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 5.30 p m.—Dr J. S. Wilkie: "An Analysis of Buffon's article *De l'Ane*, generally believed to contain the expression of his belief in a theory of evolution".

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C 2), at 5.30 p.m. —Informal Evening on "The Use of Transistors in Radio and Television". Talks by Dr. A. J. Biggs and Mr. E. Wolfendale.

Society of Chemical Industry, Plastics and Polymer Group at 14 Belgrave Square, London, S.W.1), at 6 30 p.m.—Dr A. Hochtlen: 'Polyurethanes"

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8 30 p.m.—Mr. John Heaney and Mr Martin Holdgate: 'Expedition to Gough Island".

Tuesday, October 23

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p m.—Mr. R. H. Elvery. "The Character of Concrete as an Engineering Material".*

Chadwick Trust (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. W. Emrys Davies: "The Message of Public Health—How it Should be Told"* (Chadwick Public Lecture).

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m —Mr. C. G. Giles: "Skidding Resistance of Roads and the Requirements of Modern Traffic".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Use of Electronic Computers in Nuclear Reactor Design Studies", opened by Mr. R. W. Sutton.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W 1), at 6.45 p m —"A Review of Exchange Arrangements for Engineering Students (IAESTE)". (Education Group Discussion)

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Discussion on "Functional Efficiency of Aircraft".

Wednesday, October 24

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p m —Dr. G. Popjak: "Fat Metabolism".*

University of London (at Senate House, London, W C.1), at 5 30 p m.—Dr. J. G. ten Houten (Wageningen): "Recent Advances in Plant Pathological Research in the Netherlands".*

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S.W.1), at 6 30 p.m.—Debate on the motion "That in the Opinion of This Panel, Sugar is an Unnecessary Article in the Dietary".

Thursday, October 25

University of London (at Goldsmiths' College, New Cross, London, S E.14), at 5 p.m.—Prof. P. E. Vernon: "Vocational Guidance".* (Third of six lectures of "Recent Pioneer Work in Education". Further Lectures on November 1, 8 and 15.)

Institute of Refrigeration (at the Junior Institution of Engineers, Pepys House, 14 Rochester Row, Westminster, London, S W.1), at 5.30 p m.—Mr. I. F. Eyles. "Problems of Oil Separation in Refrigeration Equipment".

Institution of Electrical Engineers (in conjunction with the British Nuclear Energy Conference, at Savoy Place, London, W C.2), at 5.30 p.m.—Dr L R. Blake: "Conduction and Induction Pumps for Liquid Metals".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Sir Gavin de Beer, F.R.S.: "Science and the Humanities"* (Rickman Godlee Lecture).

Friday, October 26

Royal Institute of Chemistry (in the Sir William Beveridge Hall, Senate House, University of London, W.C.1), at 3 p.m.—Conference on "The Education and Training of the Chemist".

Royal Society of Medicine, Pædiatrics Section (at 1 Wimpole Street, London, W.1), at 5 p.m —Dr. D. V. Hubble: "Hormonal Influences on Growth" (Presidential Address).

British Psychological Society, Education Section (at the University of London Institute of Education, Malet-Street, London, W.C.1), at 6 p m —Mr. W. A. Belson: "Educational and Psychological Aspects of Audience Research in the B.B C.".

Institution of Mechanical Engineers, Applied Mechanics and Lubrication Groups (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m —Mr. G. W. K. Ford, Mr. D M Harris and Mr. D. Pantall. "Principles and Applications of Hydrodynamic-Type Gas Bearings".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Sir Ronald Nesbitt-Hawes: "Educational Needs of a Technical Age"*. (Third of ten University Extension Lectures on "Technology and Industry". Further lectures on November 2, 9, 16, 23, 30, December 7 and 14.)

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Harold C. Urey: "Diamonds, Meteorites and the Origin of the Solar System".

Saturday, October 27

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Sylvia Matheson: "Time Off to Dig: an Archæological Excavation in Afghanistan".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Analytical Chemist (with at least a first- or second-class honours degree in chemistry, good general analytical experience and preferably a special interest in physical methods) to be deputy to the Chief Analyst—The Personnel Officer, The Radiochemical Centre, U.K.A.E.A., White Lion Road, Amersham, Bucks, quoting Ref 649/34 (October 25).

Physical Chemist (with a first- or second-class honours degree in science or equivalent qualifications) in the Technological Irradiation Group of the Isotope Division, to study physical and chemical changes induced by radiation—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 658/2 (October 25).

Assistant Lecturer (preferably with special qualifications and interests in mineralogy and petrology) in Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (October 27).

Chief Scientist (with good academic qualifications and experience in the administration of a large laboratory) in the Warwickshire Area —The Divisional Chief Staff Officer, National Coal Board, West Midlands Division, Himley Hall, Dudley, Worcs (October 27).

Chemist or Physicist (with a first- or second-class honours degree, and preferably postgraduate experience or experience with tropical soils) at the Rubber Research Institute of Malaya, Kuala Lumpur, for work on soil problems—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (October 31)

Lecturer in Mathematics—The Secretary of University Court, The University, Glasgow (October 31).

Lecturer (preferably with qualifications in organic chemistry) in Chemistry—The Registrar, Trinity College, Dublin (November 1).

Lecturer in Physics—The Secretary, The University, 38 North Bailey, Durham (November 3).

Chair of Chemistry in the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 8)

Associate Professor of Physiology in the Faculty of Rural Science, University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 12)

Lecturer in Physics—The Registrar (Room 9, O.R.B.), The University, Reading (November 12).

Lecturers or Assistant Lecturers (2) in Metallurgy—The Registrar, The University, Leeds 2 (November 12).

Chair of Chemistry in Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 13).

Lecturer or Senior Lecturer in Dental Biochemistry at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Botanist (with a first- or second-class honours degree) in the Pomology Department, to work on taxonomic problems in connexion with the Institute's plant breeding work—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee (November 17).

Research Assistant and Demonstrator (preferably with a knowledge of cytogenetics) in the Department of Botany—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 17).

Senior Lecturer (preferably with qualifications in applied mathematics) in Mathematics, at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 17)

Senior Lecturers or Lecturers in Veterinary Anatomy and Veterinary Medicine and Surgery at the University of Khartoum —The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 26).

Biochemist for investigational work which will include biochemical, chemical and physical analyses of tobacco from fertilizer, rotation, variety, breeding and other experiments now in progress—The Director, Tobacco Research Board of Rhodesia and Nyasaland, P.O. Box 1909, Salisbury, Southern Rhodesia (November 30).

Lecturer or Assistant Lecturer (with qualifications in biology and experience in teaching) in Education—The Registrar, The University, Leeds 2 (December 1)

Lecturer (with interests in biophysics or biochemistry) in Chemical Microbiology—The Registrar, The University, Liverpool (December 1).

Appointments Officer (with some experience and a sound scientific background) to interview applicants and recruit staff throughout the organization—Dr B. B. Goalby, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22.

Assistant, Grade B, to teach Physics—The Principal, Technical College, Queen Street South, Huddersfield.

Computer (under 40, with a degree in mathematics) in the Lands and Survey Department, Government of Tanganyika, for the computation of surveys of a geodetic, astronomical or cadastral nature, and the keeping of records—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.107/8/06.

Entomologist at the Royal Horticultural Society's Gardens at Wisley, Surrey, for duties principally advisory and instructional, but may include research work on insect pests affecting horticultural plants—The Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1, marking envelope "Confidential".

Field Officer (Agriculture) (aged 30/40, with sound tropical experience of experimental farm management and a knowledge of preparing and recording experiments) in the Tanganyika Government Agricultural Department—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3A/43540/TA.

Geophysicist (preferably with a first- or good second-class honours degree in physics and mathematics and a background of geology) in the Geological Survey Department, for water supply work, mineral exploration and general geological survey—The Director of Geological Survey, P.O. Lobatsi, Bechuanaland Protectorate.

Lecturer in Physical Chemistry—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham.

Metallurgist or Metal Physicist in the Metal Physics Section of the Physics Department, to lead fundamental research work on liquid and solid state problems concerned with the deformation characteristics of both single crystal and polycrystalline metals, with melting and solidification and with time-dependent processes generally—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "M.P.I.".

Research Assistant (chemistry graduate, preferably with previous analytical experience) for work on special methods of trace analysis—The Head of the Geology Department (Geochemical Prospecting Research Centre), Imperial College, London, S.W.7.

Research Assistant for research in biochemistry in connexion with the central nervous system and mental disease.—The Secretary, Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5.

Research Assistant (with experimental aptitude and a sound knowledge of mathematics to G C.E. advanced level) in the Fluid Dynamics Section of the Physics Department in London, to take part in the investigation of boundary layer flow and other basic problems of fluid mechanics—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "D.3".

Research Fellow (with a research degree or research experience) in Inorganic Chemistry, to investigate the chemistry of metal complexes of importance to biological systems—Prof. R. S. Nyholm, University College, London, W.C.1.

Research Student (graduate in chemistry or biochemistry) in the Department of Chemistry, to investigate the enzymes requiring pyridoxal as co-enzyme, under the supervision of Mr C. A. Vernon and Prof. R. S. Nyholm—Prof. R. S. Nyholm, University College, Gower Street, London, W.C.1.

Senior Laboratory Technician (male) in the Science Department, to be responsible for the Laboratories (chemistry, physics, biology), the other laboratory staff and all equipment and stock—The Principal, North-West Kent College of Technology, Miskin Road, Dartford, Kent.

Senior Plant Pathologist (with a good honours degree in botany, postgraduate training in plant pathology, and practical experience of investigating the problems arising from widespread attacks of plant diseases) at the West African Cocoa Research Institute, Gold Coast, to take charge of the Pathology Division and to carry out research on virus diseases of cocoa—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/200/01.

Senior Research Assistant (with a good honours degree in metallurgy or physics, practical experience, and/or research training) in the Faculty of Applied Science, to work in the field of creep and fatigue of ferrous materials—The Registrar, The University, Nottingham.

Senior Scientific Officer (with an honours degree in mechanical engineering or equivalent) with the Ministry of Fuel and Power, for work at Headquarters, London, in connexion with the conception and development of novel sources and uses of fuel and power, and for the supervision of a coal study laboratory, National Gas Turbine Establishment, Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.655/6A.

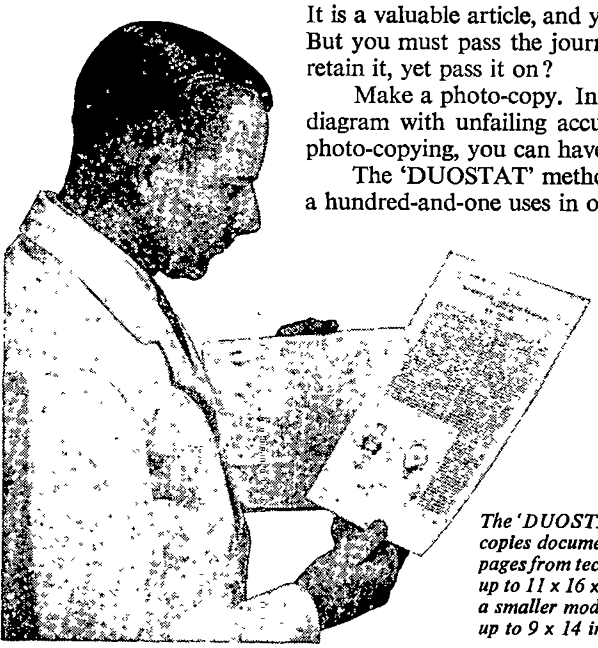
Recent Scientific and Technical Books Supp. viii

An article from 'NATURE'

It is a valuable article, and you wish to retain it for personal study and reference. But you must pass the journal on to others in your organisation. How can you retain it, yet pass it on?

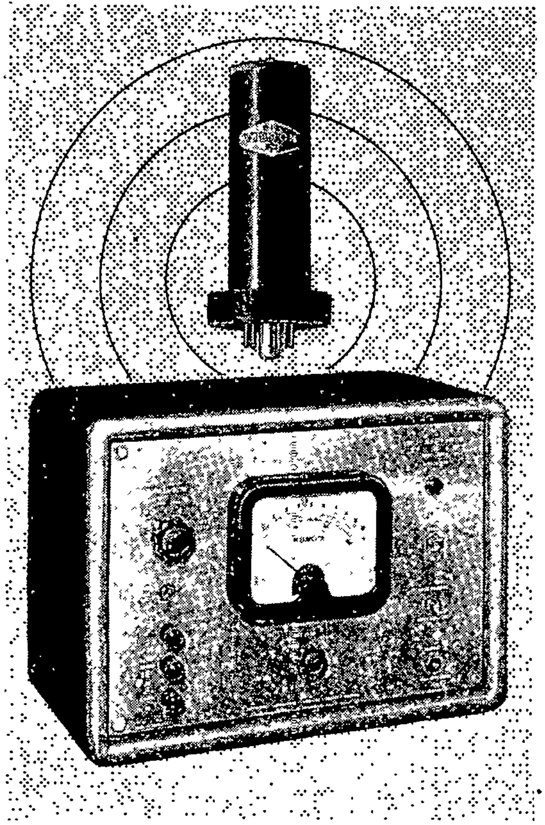
Make a photo-copy. In this way you can reproduce every word, symbol and diagram with unfailing accuracy. And, if you use the 'DUOSTAT' method of photo-copying, you can have your copy in less than three minutes.

The 'DUOSTAT' method is convenient, clean and inexpensive. And it has a hundred-and-one uses in offices and laboratories. Let us send you details.



Kodak
LIMITED
Industrial Sales Division
Kodak House, Kingsway
London, W.C.2

The 'DUOSTAT' Printer Model 14/18 copies documents up to 14 x 18 inches, pages from technical journals and books up to 11 x 16 x 1½ inches. There is also a smaller model for copying documents up to 9 x 14 inches.



E·I·L

The VIBRON

is a new electronic component, which replaces the electrometer valve in the measurement of very small currents.

The VIBRON has made it possible to design circuits for measuring currents as small as 10^{-16} ampere, or resistances as high as 10^{15} ohms, to an accuracy of ±2%, and with a zero stability of ±100 microvolts in twenty-four hours. It can be supplied as a unit for building into instruments of your own design, or, alternatively, VIBRON instruments of several types are available from E.I.L.: the Model 33B Electrometer shown here is an example.

DEPLOYMENT OF SCIENTIFIC AND TECHNICAL MAN-POWER

JUST over ten years ago, the Barlow Committee presented its report on scientific man-power in Britain, recommending that the nation should double its present output of scientists to give roughly 5,000 newly qualified scientists per annum at the earliest possible moment. The Committee's calculations visualized a demand for some 90,000 scientists by 1955, and it is common knowledge that the universities in actual fact doubled their output of scientists and technologists by 1950, though in 1956 the shortage of scientists and technologists continued unabated and, despite some unemployment among particular categories of scientists, fears as to possible over-production of scientists and engineers have been completely dispelled by events.

The Barlow Committee made no attempt to assess the demand for particular categories of scientists, recognizing that to do so would involve a formidable statistical inquiry which, if attempted, would seriously delay the presentation of its report. The then newly formed Advisory Council for Scientific Policy was charged with the responsibility "to advise the Lord President of the Council in the exercise of his responsibility for the formulation and execution of Government and scientific policy", and has in particular been asked to make recommendations about "the arrangements for securing an adequate flow of scientific man-power to meet the needs both of Government and industry". The Barlow Committee thus wisely left for later attention the determination of the demand for each particular type of scientist, and in December 1950 the Advisory Council appointed a Committee on Scientific Man-power under the chairmanship of Prof. (now Sir Solly) Zuckerman, "to study the future needs of scientific and technological manpower for employment both at home and abroad and to report to the Council from time to time".

A report from this Committee was issued as the Advisory Council's fifth annual report in May 1952, and this was followed last November by a report on the recruitment of scientists and engineers by the engineering industry. The report on scientific and engineering man-power in Great Britain which has now come jointly from the Advisory Council and the Ministry of Labour and National Service (see p. 887 of this issue of *Nature*) embodies the results of a further inquiry by this Committee and of one initiated by the Ministry of Labour which go some way towards meeting this need for further statistical detail. Admittedly there is a certain amount of conjecture and the Committee on Scientific Man-power is probably right in suggesting that it is impossible to predict the rates at which the annual flow of newly qualified people and of the total stock of scientists and engineers in employment are likely to increase, nor does it deny that there are still gaps in our knowledge as to the existing situation. The figures for scientists and engineers in manufacturing industry may still be subject to some margin of error. The exclusion of the small firm, with fewer than a hundred employees, may not seriously affect the present estimate, even although such small firms constitute by far the majority; but it could seriously affect the potential demand if Britain is to maintain its competitive position in the world's markets.

Again, the Committee points out that we have no clear idea of what proportion of science graduates take up work in their respective fields in Great Britain. It also notes that its figures for the employment of scientists in the public sector of the economy, including teaching, reflect current policy, which may well differ from future policy; nor is the assumption sacrosanct that, on the average, the number of scientists and engineers employed in industry will increase in proportion to increases in output. None the less, it believes that this view is better than any other on which it could base its calculations, and, whatever the weaknesses in its interpretation of future needs, the assessment in the present report has the undoubted merit of starting with a more accurate picture of the employment of scientists and engineers to-day.

In place of the estimated demand in 1955 of 90,000 and the 64,000 qualified scientists which were considered as likely to be available on the plans then existing (which provided for some 5,000 additional scientists and technologists annually), the present inquiry by the Ministry of Labour puts the number of scientists and engineers employed in Great Britain early in 1956 as just short of 120,000, of whom some 51,000 are scientists and just short of 69,000 engineers. It is estimated that there are a further 5,000 scientists and 10,000 engineers in fields not covered by the inquiry. While both reports use the term 'qualified scientist' in the same sense, the Barlow report made no estimate for engineering and related technologists, which before the War accounted for about 40 per cent as many engineering students as the pure science schools. It would appear, however, to include those qualified in agricultural or veterinary science, who are excluded from the present report, and also to include those working in the Oversea Civil Service, who are likewise excluded from the present report.

The Committee on Scientific Man-power is well aware of the discrepancies between the present estimate and that of the Barlow Report and other earlier inquiries, and it does not suggest that they are entirely accounted for by the omission from the present inquiry of scientists working abroad. Earlier inquiries, it is suggested, may have made insufficient allowance for women science graduates who are no longer in employment but the greater part of the difference is attributed to science graduates who have taken employment in other fields—for example, men with degrees in physics now classified as engineers, mathematicians now working as actuaries, or men and women with qualifications in science now in employment in which such qualifications are not demanded. The number of qualified engineers revealed by the inquiry, however, agrees reasonably well with other calculations based upon the number of past awards of university degrees and corresponding qualifications in the engineering sciences.

Such discrepancies are of minor importance in relation to the actual number of scientists and engineers working in Great Britain. The major interest of the report is in respect of the assessment of the probable future demand for scientific and engineering man-power. For the first time, a goal is set for the expansion of technological education and of scientific studies at the universities, based on a reasoned estimate of the future demands in Britain for scientists and technologists. Even without taking account of overseas demands, of certain relatively small categories such as agricultural and veterinary scientists and ignoring the problematic but possibly considerable and important demands of the small firms and, presumably, the requirements of management and administration for men qualified in science as well as in administration, the report is emphatic that the output of 10,000 scientists and technologists a year which the universities had achieved in four years from the appearance of the Barlow Report is quite inadequate. To come within sight of meeting the minimum needs of Britain's economy, we must aim at doubling that figure and achieve an annual output of roughly 20,000 by 1970.

In this figure, the Committee does not differentiate between scientists and engineers, and accordingly the estimate is not affected by the transference in employment from one category to another. It has, however, included an allowance of 25 per cent for overseas students, emigration, etc., as well as for the continuance of some measure of shortage. This is wise, for there are certain respects in which Britain's economic strength lies in its ability to provide trained man-power, as, for example, under the Colombo Plan and the Expanded Technical Assistance Programme, or again in relation to nuclear energy. Any realistic appraisal of Britain's needs for trained scientific and technical man-power cannot be limited to those employed in the country itself, but must take some account of overseas requirements and perhaps especially for the under-developed areas.

Before examining the distribution of scientific and technological man-power in relation to the future demand, there is one point to be noted which receives little attention in the present report. The Committee does not doubt that sufficient talented boys and girls will be available, if they choose to take up careers in science and engineering, to be trained at the rates which it recommends should now form the basis of national policy. It is not for the Committee, but for the University Grants Committee and the various education departments to consider how these probable demands for graduates in pure and applied science are to be met; but it will be noted that the Committee recommends that, provided there is no lowering of standards, the universities should attempt to provide as much as possible of the necessary expansion. In its view, there is little risk that the greatest possible combined efforts of the universities and technical colleges will result in any over-production of professional scientists and engineers during the 1960's.

The nation's demand for trained man-power depends in part on the way in which that man-power is used. That is to say, it depends on that man-power being employed in occupations in which scientific or technological training can be put to effective and efficient use. The efficient use of trained man-power requires not only the provision of necessary equipment and appropriate conditions of work but equally the provision of the appropriate ancillary technicians and facilities. If the research worker, for example, is not provided with the appropriate assistance, his time may be wasted on occupations for which much less highly trained and skilled persons could be used and which he himself performs less efficiently.

We cannot, in fact, separate consideration of the probable demand for scientific and technological man-power from that of the demand for technicians and a corollary of the present survey is, in the first place, some attempt to assess the efficiency with which scientific man-power in Britain is at present being used. It might well be found that if we used our existing resources of highly trained man-power more efficiently, the existing shortage would be less acute; and that Britain's needs could be met by some less expensive means than doubling the present number of scientists and engineers. Changes such as those which have recently been discussed in connexion with what is commonly described as automation have pointed in this direction, and the disappearing differential in salary or wage between the technician and scientist or technologist can have consequences that make it essential for closer consideration to be given to this aspect of our needs for trained man-power.

The expansion of technical education in Britain cannot be planned reasonably without some estimate of the nation's need for technicians, and here again it cannot be too strongly emphasized that any attempt to force the expansion of the technical colleges to provide professional engineers and technologists which hinders their primary and essential function of providing technicians is detrimental to the nation's interests, and may well involve waste of highly trained man-power. The Committee on Scientific Man-power does not, however, consider the question whether we have sufficient talent to provide simultaneously this doubled output of scientists and engineers, and also the output of technicians necessary to sustain that number efficiently. The present output of technicians might well require to be trebled or more, and there was no suggestion in the recent White Paper on Technical Education that the implications are appreciated by the Minister.

The picture of the present distribution of scientists and engineers in Great Britain which is given in this report has other implications in regard to the expansion of the present output. The report assumes a 100 per cent increase in the requirements of the universities over the next ten years; but its assessment of requirements for teaching in secondary schools makes no provision for any further concentration on scientific subjects, or for any improvement in existing staffing ratios. It suggests that an addi tional 4,000 science graduates would be a reasonable allowance for the latter, and this could well have an important bearing on attracting the increased number of boys and girls to take up careers in science and technology, as well as in raising standards of training.

The bearing of the quality of teaching on the supply of graduates in science and engineering appears to have received relatively little attention, and the wide variation in the proportion of those who take up teaching—in schools, colleges and universities —between different categories of scientists and engineers may not be without significance. Whereas only 5,643 out of 20,692 chemists and 4,751 out of 10,484 physicists are to be found in education, 442 out of 894 geologists, 3,381 out of 4,838 biologists and 9,302 out of 11,482 mathematicians are so occupied. Out of a grand total of 68,456 engineers, however, only 2,429 are teaching, and of these 1,712 (out of 19,533) are electrical engineers. Even when all due allowance is made for the concentration of those teaching engineering, for example, in the universities where the numerical requirements are much smaller than in the schools, and for the possibility of part-time seconding of staff from industry for teaching in the technical colleges, there may be some room for inquiry here if we are to overcome the reluctance of some parents and school authorities to encourage their pupils to enter on scientific or technical careers.

Here, of course, there operates too the differential factor in regard to salaries, and it should not be assumed too readily that the expansion recommended in this report will necessarily provide Britain with the distribution of trained man-power that is desirable unless appropriate action is taken to encourage the desired distribution.

The report estimates that, of 48,829 qualified scientists employed in manufacturing industry, 21,734 are engaged in research and development; while of 17,078 employed in the nationalized industries, only 2,526 are so engaged, of whom 1,706 are with the Atomic Energy Authority. Of the 13,850 employed by the central government, 2,350 are employed by the research departments, that is to say, the Department of Scientific and Industrial Research, the Agricultural Research Council, the Medical Research Council and the Nature Conservancy; but of the 7,600 employed by the defence departments, a number will obviously also be engaged on research. There is no indication of what proportion of the 3,250 scientists and engineers employed by the universities are engaged on research; of the total of 71,122 scientists and engineers employed in industry, only 1,397 are employed by the research associations.

There thus appears to be no firm basis for the belief that the research associations take an undue proportion of Britain's scientific and technical man-power. Nor does the report substantiate the view that, so far as scientists and engineers are concerned, an excessive proportion of trained man-power is employed on defence. Moreover, when we make an appropriate allowance for those of the 21,734 scientists and engineers engaged in research and development work in industry who are occupied on work that is development or merely the systematic exploration of a known field by recognized techniques rather than fundamental inquiry, it is clear that the proportion of men trained in fundamental investigation by industry annually is relatively small compared with those trained in the scientific outlook. This also might well bear on the character of the training given in the universities and colleges of technology, and any expansion of the order recommended in this report can scarcely fail to take account of the possibility that methods of training and particularly of the practice of teaching research may merit re-examination. Otherwise there could well be waste of man-power in teaching as well as ineffective teaching.

Some of these fears find expression in the report on the recruitment of scientists and engineers by the engineering industry, and although the Committee on Scientific Man-power does not here revert to them, it may be taken that they will not be overlooked. If we are to attract this higher proportion of Britain's youthful talent into the channels that this report recommends, we must take every care to see that the training given is appropriate to its purpose, and that the talent so trained is wisely and efficiently used and, so far as possible, where it will best serve the national need. The report establishes a reasonable case for the projected expansion of technological education in Britain and for the expansion which the universities are expected shortly to announce for the forthcoming quinquennium. It can scarcely fail to raise fresh doubts, however, as to the adequacy and even the soundness of the Minister of Education's plans for the expansion of technical education, or as to the extent to which the Government has really grasped the implications of the present situation and what is involved in the efficient use of trained man-power. At least, however, the report provides the starting point for a fresh assessment of the way in which the expansion of technological and technical education should be planned and executed, and for a further attempt to convince the Government of the dependence of the effective use of Britain's resources of scientific and technical man-power on those accessories such as the National Science Centre, the National Reference Library of Science and Technology and the National Science Lending Library, which the Advisory Council on Scientific Policy has hitherto ineffectively urged upon it.

BRITISH GRADUATES AND THEIR EMPLOYMENT

Graduate Employment

A Sample Survey. Pp. xiv+300. (London: Political and Economic Planning, and George Allen and Unwin, Ltd., 1956.) 30*s*.

STATISTICS of the output of coal, one of the few natural resources of Britain, would have little value if unassociated with figures of distribution and demand. The contrast between the knowledge we have about this vital national asset and our ignorance about the fate of the thousands of men and women who graduate year after year from British universities, but who are also in very short supply, is the point of departure of an inquiry by Political and Economic Planning into graduate employment. This sets out "to discover the jobs to which graduates leaving universities in Great Britain are going and the influences that determine their choice of employment; and to relate this information to such factors as age, sex, parental occupation, university attended, course taken and degree obtained".

The desirability of information of this kind has been recognized ever since 1946, when the Barlow Committee's Report on Scientific Man-power sowed the seeds for what has become a widespread concern about Britain's chronic shortage of scientists and engineers; about the deleterious effect of the shortage on our national position; about the scarcity of teachers of science and mathematics; and about the failure of our educational system to weave into the pattern of general culture an appreciation of scientific matters, and more important, an awareness of the incredible speed with which their influence over human affairs is growing.

The difficulty has always been, and still remains, that it is far simpler to find out what human beings do with the things they produce, than to discover how they dispose of themselves. We know that there is a shortage of scientific man-power. But we have few precise ideas about the present stock and distribution of scientists and engineers in employment as such; about the extent of the shortage in different fields of employment; about its probable duration in the light of steps that have been taken to overcome present difficulties; and about the fate of our science and engineering graduates. Until the recent inquiry instigated by the Ministry of Labour and National Service [see this issue of *Nature*, p. 887], we have had to rely on actuarial analyses of the numbers of graduates turned out in past years to get any idea about the first of these questions. So far as the last is concerned, we have had to accept the fact that it would be extremely difficult for the universities to keep a record of the subsequent careers of the men and women who graduate from them.

Just how difficult emerges from the P.E.P. inquiry, which began in 1953 under the sponsorship of a Joint Committee of the Department of Scientific and Industrial Research and the Medical Research Council, with the aid of U.S. Counterpart Funds. Because of the immense labour involved, the study was confined to a sample of one in two of the male graduates of 1950 in arts, science and technology from English, Welsh and Scottish Universities. Nearly seven thousand questionnaires were sent out; replies were received from about two in every three. For all practical purposes, therefore, this means that P.E.P. was unable to find out anything about the whereabouts of one-third of all graduates as little as four years after they had left their universities. Of the men who replied, nearly two-thirds came from grammar schools or their Scottish equivalents. An even higher proportion received some form of public financial help when at the universities. Just over half read for an arts degree; 28 per cent for a science degree; and 20 per cent for a technology degree. On graduating, the technologists tended to go straight into employment, whereas large numbers of arts men and scientists tended to stay on for further study. More than a third of those who obtained first-class degrees stayed on for at least two years; and—most interesting—half the sample started their university careers without any clear idea about what they were going to do afterwards; while two in three held that the decisions that they finally took about their future work were reached entirely independently, without outside influence. In the event, 30 per cent went into industry and 23 per cent into teaching.

These are only a few of the interesting facts that emerge from the P.E.P. study. But, as the volume itself points out, it is necessary to remember that the conclusions reached relate only to a short period in the history of one batch of graduates, and to a year, 1950, which must have included many men who had been on active service during the Second World War. The survey is, therefore, a cross-section of a particular piece of history. Because of the immense labour involved, it also had to be an incomplete cross-section. For example, the women graduates of 1950 were not included. On the other hand, the value of the work is greater than just the straightforward, even if limited, facts that it discloses. For example, it throws up this critical question. If half the people going to the universities of Britain have no clear idea about what they wish to do afterwards, and believe they are uninfluenced in their decisions as to which posts to take up after graduation, what is the value of all the propaganda that has been going on about Britain's need for more scientists and engineers? Or does its apparent ineffectiveness relate only to people who graduated in 1950? Equally important, how quickly will the market mechanism, in the form of higher salaries paid to engineers and scientists, operate against the social conventions which in some numerically small but influential corners have for so long placed a higher prestige value on a university education in the arts? But perhaps the most important issue which P.E.P.'s valuable study underlines is the need for regular, even if not detailed, returns about graduate employment in Britain. There can be little doubt that if it were possible to arrange for a steady flow of such information, the task of those who are concerned with ministering to the growth of our universities, technical and other training colleges and schools, would be greatly eased.

S. ZUCKERMAN

INTERNATIONAL ENCYCLOPÆDIA OF UNIFIED SCIENCE

International Encyclopedia of Unified Science
Edited by Otto Neurath, Rudolf Carnap and Charles Morris. (Combined edition.) Vol. 1, Part 1 (Nos. 1–5): Pp. ix+1–340. Vol. 1, Part 2 (Nos. 6–10): Pp. iv+341–760. (Chicago, Ill.: University of Chicago Press; London: Cambridge University Press, 1955.) 41*s*. 6*d*. net each part.

COMMENCED in 1938, the introductory material of the "International Encyclopedia of Unified Science" has been published at intervals by the University of Chicago and is now issued in a combined edition as Vol. 1, which is divided into two considerable parts. Each of the two parts contains five sections of seventy or eighty pages each. The idea from which the work developed was that of Otto Neurath, of Isotype fame, who conceived a scheme which should continue the work of the French "Encyclopédie" of the eighteenth century. Unified science became historically the subject of this "Encyclopedia" as a result of the efforts of the Unity of Science movement, which includes scientists and persons interested in science who are conscious of the importance of a universal scientific attitude.

The new version of the idea of unified science is created by the confluence of several intellectual currents. Empirical work of scientists was often antagonistic to the logical constructions of *a priori* rationalism bred by philosophico-religious systems; therefore 'empiricalization' and 'logicalization' were considered mostly to be in opposition: the two have now become synthesized for the first time in history. Certain empiricists began to appreciate logical analysis and construction as universal scientific aids; other thinkers, especially interested in the historical importance of scientific imagination, stress their opposition to all kinds of *a priori* reasoning and demand empirical tests for all their theories. The terms 'logical empiricism' and 'empirical rationalism' express very well this new type of synthesis. The terms 'unified science' and 'unity of science' are becoming more and more widespread in usage. The annual congresses devoted to the unity of science held first at Charles University in Prague in 1934 were disturbed by the Second World War, and a number of the leading members have since died, but the movement continues. Physicists are familiar with co-operation in the field of physics, and biologists in the field of biology: the movement for unified science stresses the need for further co-operation—physicists with biologists, biologists with sociologists, and other specialists with logicians and mathematicians.

The "International Encyclopedia of Unified Science" endeavours to show how various scientific activities such as observation, experiment and reasoning can be synthesized and how all these together help to evolve unified science. The busy research worker may not find himself in sympathy with some of the painstaking accounts of the logical and philosophical foundations on which his subject rests; but, nonetheless, they are of prime importance. The flowing tide of nineteenth-century science was too hurried to regard the work of J. S. Mill.

The editors of the present works have been fortunate in the choice of authors. Otto Neurath opens the introductory monograph with an essay on unified science as encyclopædic integration; John Dewey discusses unity of science as a social problem; Rudolf Carnap analyses the logical foundations of the unity of science; and Charles W. Morris, in his essay on empiricism, attempts to formulate a general framework for the encyclopædic enterprise as a whole. There are two short papers: by Niels Bohr on analysis and synthesis in science, and by Bertrand Russell on the importance of logical form.

In the second section, Charles W. Morris outlines the field of the theory of signs, showing the place of this within the unity of science movement. He also examines in turn the main sub-divisions of semiotic (theory of signs), syntactics, semantics and pragmatics. This is followed by Rudolf Carnap's study of the foundations of logic and mathematics, which considers the nature and interpretation of a calculus and calculi and their application in empirical science.

Leonard Bloomfield's monograph is concerned with the nature of linguistics as a science, the devices of natural languages used to attain precision, the special characteristics of the language of science, the place of linguistics in the scheme of science, and the relation of linguistics to logic and mathematics. Victor F. Lenzen deals with the various procedures of empirical science, techniques of observation and the various procedures of systematization. Part 2 has five sections: the principles of the theory of probability, by Ernest Nagel; the foundations of physics, by Philipp Frank; cosmology, by E. Finlay-Freundlich; the foundations of biology, by Felix Mainx; and finally, the conceptual framework of psychology, by Egon Brunswik.

The seven hundred and sixty pages of the two parts of Vol. 1 are not all easy reading; but it would be difficult to think of a more convenient and concentrated account of what must be regarded as a necessary foundation for any superstructure of specialized scientific knowledge, system of techniques or principles. Much of the teaching of science to-day gives us an impression of the branches and leaves of the tree of science but little of its trunk and roots.

W. L. SUMNER

LUDWIG MOND

The Life of Ludwig Mond

By J. M. Cohen. Pp. xv+295+17 plates. (London: Methuen and Co., Ltd., 1956.) 22*s*. 6*d*. net.

RARELY does the biography of a father follow that of his son by well-nigh a generation, and when that happens it is not too easy to avoid a certain amount of repetition. Mr. J. M. Cohen's book differs profoundly from Hector Bolitho's life of "Alfred Mond: First Baron Melchett" (1933), though in narrative and anecdote he has drawn to some extent on the earlier part of Bolitho's book, particularly in respect of Ludwig Mond's early days in the chemical industry, the venture at Winnington and the early association of his two sons with Winnington. Only at such points do the two books touch, however; there is the stamp of Mr. Cohen's own personality on the successive chapters in which he depicts the education of a scientist, his apprenticeship in the infant chemical industry, the conflict of interests which finally issued in Mond's settling in Britain and not in Holland and the founding and growth of the Winnington works. There emerges a vivid and fascinating picture of a great industrialist which can be read with as much ease and pleasure by the layman as by the technologist.

It is a portrait which is highly pertinent for these days when men like Sir Henry Tizard are wondering whether British manufacturers are becoming less
enterprising. Here is told [redacted] in which enterprise
is writ large and in which ths often sedulously
fostered about those capital as well as
brains and judgment ufacturing ventures
are dealt some shrew There stands out the
determination and ce of Ludwig Mond,
his versatility and nius, his devotion to
research and his for conservation and
the recovery or waste, as well as some-
thing of his id al relations, in which he
was a pioneer vine contributes a series
of technical ich give the background
of Mond's vements and review the
decline an lanc soda system, and also
a postscr very briefly, the story of
the Mon the chemical industry to
its term mpts a brief appreciation of
his ach

Yet lity of 'the old doctor', as he
was on, emerges vividly in these

pages and his achievements are mentioned, the book does not really measure his technological stature. In that respect, indeed, it falls short of Mr. J. I. Watts's admirable obituary notice in the *Transactions of the Chemical Society*. Nowhere is the reader given the clear appraisal of Mond's outstanding achievements that the chemist might expect and the layman needs. Nor does the book display at all adequately the vigour and range of Mond's own thought and philosophy, much of which is highly relevant to our own times.

This is the more unfortunate in that the book contains no list of Mond's own writings or addresses, nor any list of his nearly fifty British patent specifications. Nor is there more than incidental reference to such important contributions as the founding and development of the Society of Chemical Industry, the steady support he gave to the improvement of the Royal Society's catalogue of scientific papers and afterwards to the cataloguing of international scientific literature, and the endowment of the Davy–Faraday Laboratory at the Royal Institution, London. Failing to relate Mond's outlook and thought to our current problems, the book lacks something of the inspiration it could well have had for the younger generation, and the absence of references detracts a little from its value as a contribution to industrial history.

For all its merits, the book is not the book that H. E. Armstrong would have given us had he lived to complete the task to which he set his hand. Into whatever by-ways Armstrong might have strayed, we may be sure that he would have fully displayed the vigour of his friend's mind and the relevance to our times, for example, of Mond's ideas on the training of the scientist when he pressed the claims of a thorough grounding in theoretical science, even to the extent of disputing the value of teaching applied science, or again of his ideas as to the possibility of a science of invention. It is in such addresses as those which Mond gave at the opening of the Schorlemmer Laboratory in Manchester or as president of the Society of Chemical Industry, when he argued that the steady methodical investigation of natural phenomena is the father of industrial progress, that we find the industrial philosophy which was one of Mond's most stimulating characteristics. The achievements are displayed in Mr. Cohen's book, but something more is wanted to bring the reader easily into contact with the vigour and stimulus of Mond's thought.

R. Brightman

FRENCH AT[illegible]F THE FUNGI

Nouvel Atlas des C[illegible]s

Par Henri Romagnes[illegible] (Publié sous les auspices de la Société[illegible]de France.) Pp. 96+79 planches. (P[illegible] 1956.) 5550 francs.

It is so seldom nowada[illegible]ver is able to give whole-hearted p[illegible]paper, type and binding of a scientific[illegible]ems proper to make immediate comm[illegible]over, the author, Henri Romagnesi, [illegible]most, as he is one of the most activ[illegible] modern school of French mycologist[illegible]

The present volume is th[illegible]d the plates figure species of *Lact*[illegible]*iota*, *Psalliota*, *Amanita* and all genera with coloured spores. The second volume, which is to be published at the end of the year, will include agarics with white spores, the remainder of the Basidiomycetes, morels and other large Discomycetes. The final volume will be of rarer species and those of which no good figure has been published, and, presumably, will not be long delayed.

The introduction, eighty pages in length, gives a general summary of the nature of fungi and their classification; structure; physiology; reproduction; poisonous fungi; edible fungi (with recipes for cooking); and principal genera and sub-genera. Although this is a popular book, it is not written exclusively for beginners but is a thoroughly up-to-date, though concise, account of the matters treated therein, with a view to a wider appeal. Certainly, many who profess and call themselves mycologists will find much for thought and, indeed, not a little to learn here. (It is news to me that the cultivation of mushrooms "en cousine" is still sometimes practised in hotels in Britain.) There are twenty-two text-figures, several of them detailed and occupying a whole page.

As is perhaps to be expected in a French work, a good deal of space is devoted to classification. There is a general outline in the first chapter, and the final thirty-four pages provide details. A series of dichotomous keys gives a clear idea of the macroscopic characters useful in differentiating between different genera and sub-genera of the Agaricales. The remaining Basidiomycetes are treated in somewhat less detail. The families of Discomycetes and Tuberales are also keyed.

The seventy-nine plates depict a little more than a hundred species and varieties. They are reproduced lithographically in eight to twelve colours from originals in the collections of the French Mycological Society, and most of them are by Dr. J. Chenantais. Unfortunately, the drawings which he bequeathed to the Society did not include all the species needed for this work, so those of others were added, mostly by Col. A. Lacaze. In my view, those of Chenantais are among the best that have ever been published, rivalling in beauty and in exactness those of E. Boudier's "Icones Mycologicae", though without microscopic details.

A page of description accompanies each plate. The descriptions are clear and include all the microscopic details necessary for exact and intelligent identification. The notes on habitats are full and often contain interesting facts such as only one with Romagnesi's vast experience as a collector could supply: those on "importance pratique" are concerned solely with gastronomy.

Where a species is likely to be confused with one or more others, the contrasting characters are listed in parallel columns. Only experience shows what strange confusions sometimes arise: some of those given I have not encountered. It is only by contrasting the characters one by one that misconceptions can be straightened out and confidence gained.

Most of the fungi figured are common ones, in Britain as well as in France. There are, however, a number of varieties, particularly of poisonous species, which are rarer—some of these with no previously published illustrations.

Everyone connected with the publication of this excellent work is to be warmly congratulated.

John Ramsbottom

reasonable table of p–T values fitting the measured points with the least deviation: smoothness is ensured because the relations are analytical; the table is reasonable since the derivatives conform to those as dictated by the thermodynamical behaviour of helium-4 (cf. Fig. 2 and accompanying discussion). The equations are fitted to two types of helium-4 vapour-pressure measurements, those obtained with gas thermometers (absolute) and others used as interpolation devices (relative).

Between 1·5° K. and 4·0° K. the only existing gas-thermometer measurements independent of low-temperature (below 21° K.) fixed points are obtained from ten isotherms of gaseous helium-3 and helium-4 measured by Keller[8]. In these experiments, temperatures obtained by extrapolating the isotherm data to zero density were used for calibrating a helium-4 vapour-pressure thermometer placed in the gas sample. Amounts of gas contained in the sample pipette were determined at room temperature. Above 4·2° K., vapour-pressure data have been refined by Berman and Swenson[10], who also employed a helium-4 vapour-pressure bulb in contact with a helium-4 gas thermometer. Amounts of gas in the thermometer were generally determined at the normal hydrogen boiling point; but one series of results was referred to a temperature near the helium boiling point. These two sets of gas thermometer measurements form the basis of T_{55E}. Although the temperature ranges of the two experiments do not overlap, Clement has found that the data join smoothly according to equation (1) when 20·375° K. is taken as the boiling point of hydrogen[11]. Clement has re-analysed the Berman and Swenson points, including Swenson's recalculation[12] of the data using the second virial coefficients of helium-4 as computed by Kilpatrick *et al.*[13], and finds that equation (1) fits the data above 4·2° K. with a mean deviation of 0·0020° K. At the same time, the points of Keller are fitted by equations (1) and (2) with a mean deviation of 0·0013° K. (one point having seven times this deviation and showing complete inconsistency with magnetic measurements has been omitted from this analysis and was omitted by Clement in determining the scale).

Since the gas thermometry points are not as closely spaced in temperature as would be desired, Clement has utilized two types of measurements as interpolation devices: (1) observations of the resistance of carbon resistors vs. vapour-pressure by Clement and co-workers[14] and by Corak *et al.*[7]; and (2) data of the magnetic susceptibility of paramagnetic salts as a function of vapour-pressure by Erickson and Roberts[6] and by Ambler and Hudson[15]. T_{55E} agrees with all these measurements within experimental error when the data are normalized to the gas-thermometer points. There is no theoretical basis for the resistance-temperature relation for carbon resistance-thermometers. However, the temperature-scale measurements of Corak *et al.* are calculated with reference to the dependence on temperature of the atomic heats of the noble metals, for which there is a theoretical foundation. Hence these data assume a more significant role in that when the points below 4° K. are normalized to Keller's isotherm measurements, the points above 4° K. can be considered to have validity similar to gas-thermometer data. When treated in this manner, the points above 4° K. agree exceedingly well with the Berman and Swenson points. Whereas most of the vapour-pressure data used in determining T_{55E} was obtained from apparatus using a small amount of liquid in a closed tube, it is noteworthy that measurements of this type by Corak *et al.* are in agreement with results they obtained using the bath pressure with a correction for hydrostatic head.

Scale T_{L55}

The second scale is proposed by H. van Dijk and M. Durieux, of the Kamerlingh-Onnes Laboratory, Leyden. This scale also has not as yet been published, but was presented at the Paris Conference. Copies of the scale, along with a brief description of the method used in obtaining it, have been circulated to a number of interested persons. This scale is designated as T_{L55}.

Scale T_{L55} below 4·167° K. is derived from a vapour-pressure equation which is thermodynamic in form:

$$\ln p_{mm} = i_0 + \frac{5}{2}\ln T - \frac{L_0}{RT} - \frac{1}{RT}\int_0 S_l\,\mathrm{d}T + \frac{1}{RT}\int_0^p v\ \mathrm{d}p + \ln\left(1 + \frac{B}{v_g}\right) - \frac{2B}{v_g} \quad (3)$$

where i_0 is the chemical constant, R the gas constant, L_0 the latent heat of vaporization at 0° K., S_l the liquid entropy, v_l the liquid volume, v_g the vapour volume, and B the second virial coefficient of the gas. Between 4·167° K. and 5·2° K., van Dijk and Durieux use a slight modification of the original Berman and Swenson vapour-pressure equation.

The thermodynamic form of equation (3) is a desirable feature and endows the scale derived from the equation with an aura of respectability; I must, however, caution that the form by itself does not *ensure* a close approach to the thermodynamic temperature scale; that the accuracy of any scale calculated from the equation still depends upon the reliability of the experimental data used for the calculations. We note that the p–T relation of equation (3) depends explicitly on experimental thermal and state data and, as I shall show below, only indirectly (yet importantly) on vapour-pressure measurements. An examination of the accuracy to which the several terms of equation (3) are known reveals the following: i_0 can be accurately determined from statistical mechanics; with T the independent variable, 5/2 ln T gives no trouble; the term involving v_l makes a small contribution to ln p with v_l sufficiently well known; the terms in L_0, S_l and the gas-correction factors are large, and I consider it necessary to inquire further whether the quantities entering into them have been determined with sufficient accuracy to establish a reliable p–T relation.

L_0 has not been directly determined by experiment. To evaluate L_0, van Dijk and Durieux solve equation (3) for L_0 and, using some provisional p–T relation along with the other necessary experimental quantities, obtain L_0 at a number of temperatures between 1·5° K. and 4·2° K. A constant value of L_0 would be expected if all the data were exact. Since this constancy was not achieved, the assumption was made that the gas correction terms are accurately known, so that the entropy term as derived from specific heat data contributes the only remaining uncertainty. (For a discussion of possible uncertainties in the gas correction term, see below.) Then another thermodynamic representation for L_0 is used, namely :

$$L_0 = L_T - \frac{5}{2}RT + \int_0^T C_l \mathrm{d}T + \int_0^p v_l \mathrm{d}p - \frac{RT}{v_g}\left(B - T\frac{\mathrm{d}B}{\mathrm{d}T}\right) \qquad (4)$$

where L_T are the experimentally observed heats of vaporization[16,17] and C_l is the liquid heat capacity. In equations (3) and (4) the terms involving the heat capacity occur in the solutions for L_0 with opposite signs. When L_0's from the two equations are plotted against temperature, deviations from constant L_0 will therefore be of opposite signs in regions where the errors in C_l are dominant. From this plot between 1·5° K. and 2·2° K., van Dijk and Durieux obtain an average L_0 of 59·5 joules/mole ; they accept this value of L_0 and ascribe to it an uncertainty of 0·1 joule/mole. At higher temperatures the two evaluations of L_0 diverge from this value ; van Dijk and Durieux then adjust the specific heat data between 2·5° K. and 4·2° K. so that the two coincide in this range. The adjustment of C_l is well within the experimental error of the heat capacity measurements. In making this analysis the Keesom and Schmidt[18] value of the helium-4 boiling point, judged to be accurate within 0·002° K., was obtained.

In deriving T_{L55}, van Dijk and Durieux have used for C_l "the best Leiden values". These we presume to be gathered from the 1932 data of Keesom and Clusius[19] (1·3°–4·2° K.), the 1932 data of Keesom and Miss Keesom[20] (1·3°–3·0° K.), the 1935 data of Keesom and Miss Keesom[21] (1·22°–2·28° K.), and the recent work of Kramers, Wasscher and Gorter[22] (0·25°–1·85° K.). Apparently the measurements of Hercus and Wilks[23] between 1·10° and 2·05° K. have been passed over. These results are about 10 per cent higher than those of Kramers, Wasscher and Gorter, and to my knowledge no satisfactory explanation has been offered for the discrepancy. Incidentally, use of the Hercus and Wilks data in the above analysis for L_0 would yield a value higher than 59·5 joules/mole by more than the 0·1 joule/mole uncertainty ascribed to this number. Above 2·3° K. the 1932 C_l data are the latest available. The authors[19,20] consider their results in this region to be accurate to within 3 per cent. We conclude that the entropy values derived from these C_l data are at least uncertain by 3 per cent.

To account for the effect of gas imperfection, van Dijk and Durieux use values of B calculated by Kilpatrick, Keller and Hammel[13]. These calculations were made to fit the measured low-temperature helium-4 B values[8] ; the mean deviation of the five observed B values from the calculated ones is about 1 per cent. Since the calculations serve essentially to give a smoothing function for the measurements, they can tell us nothing about the absolute accuracy of the results. Thus we feel that the calculations cannot give B as a function of T with an uncertainty of less than 1 per cent.

Let us now examine the consequences of the above discussion of the possible errors in the quantities entering the tabulation of T_{L55}. In Table 1 is listed an uncertainty, ΔT, in temperatures calculated from equation (3) when we consider the possible uncertainty in the values of L_0, S_l and B separately. We believe that the limits of error cited are all conservative estimates.

Table 1

T° K.	ΔT due to : ± 0·15 per cent in L_0	± 3 per cent in S_l or C_l	± 1 per cent in B
2·15	0·0020	0·0010	0·0002
3·50	0·0025	0·0125	0·0017
4·00	0·0027	0·0180	0·0030

This table is presented not to imply that T_{L55} is in error by as much as 0·018° K. but to illustrate the compliancy available for fitting the data. As an example, let us assume $L_0 = 59·5$ joule/mole and B correctly known ; then we insert in equation (3) the Schmidt–Keesom helium boiling point temperature, 4·2160° K., and vary C_l to obtain the chosen L_0. Next let us change the values of L_0 and B by the respective percentages indicated in Table 1 so as to produce a maximum deviation (about 0·036° K.) from 4·2160° K. when we solve equation (3) for T. We may then return to the starting temperature by making an additional change in S_l of only about 1 per cent. With these altered values we can also calculate L_T in agreement with experiment. Using T_{L55} we can apply the same procedure in the region where the error in S_l is the dominant one, above about 2·3° K. For example, at 3·50° K. and 4·00° K. we find the corresponding maximum deviations from T_{L55} to be 0·0042° K. and 0·0057° K., when we effect a 1 per cent change in B and a 0·15 per cent change in L_0. Hence we see that above 2·3° K. we can arrive at T_{L55} by simultaneous corrections to L_0, B and S_l, whereas van Dijk and Durieux correct only S_l. In other words, it is admitted at the outset that the experimental data are not sufficiently accurate to give a reliable temperature scale consistent with thermodynamics. However, it is hoped that the data can be juggled within experimental error to give such a scale. I wish to emphasize that since the three quantities L_0, B and S_l are all to some extent uncertain, the decision to alter only the most uncertain term is indeed arbitrary and offers by no means a unique approach. Conversely, if we are trying to construct a temperature scale from these quantities we have no way of knowing *a priori* how much each of the three quantities should be corrected, and we can end up with any number of scales consistent with equation (3) within the limits described above, unless we make use of suitable additional information such as experimental vapour-pressure data. Finally, below 2·3° K. the error in L_0 becomes dominant rather than that in S_l. However, we have already seen that the value of L_0 chosen by van Dijk and Durieux is in itself strongly dependent upon the choice of specific heat data in this region.

Numerical Comparison of T_{L55} and T_{55E}

A graphical comparison of the two proposed scales is shown in Fig. 1, where $T_{L55}–T_{55E}$ is plotted against T. It is noticeable that below 4·2° K. the two scales differ by at most 0·0036° K. ; but I am struck by the fact that above 4·2° K. the difference increases to about 0·012° K. at 5·2° K., even though in this region both scales are based on the Berman and Swenson[10] data. Van Dijk and Durieux have bodily shifted the original Berman and Swenson equation by about 0·001° K. (in the direction of better agreement with T_{55E}) in order to make it join with the thermodynamic calculation at 4·167° K. However,

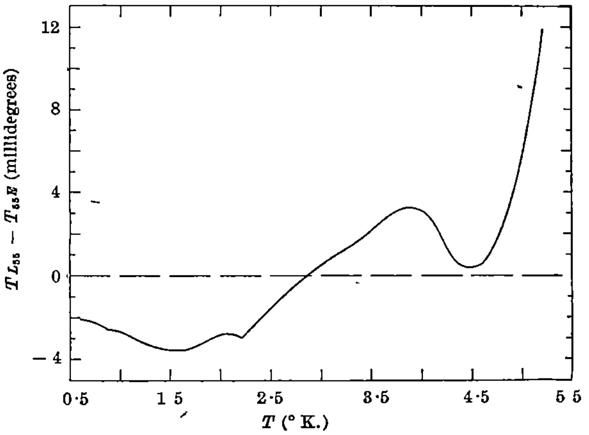

Fig. 1. Deviations of scale T_{55E} from scale T_{L55} in millidegrees plotted against the temperature in degrees Kelvin

serious difficulties are encountered in making this junction, as shown in Fig. 2, where the plots of $-\left[\frac{5}{2}T + \mathrm{d}\ln p/\mathrm{d}\left(\frac{1}{T}\right)\right]$ vs. T for the two scales are compared[24]. Since we know of no anomaly occurring above the λ-point for helium-4, we expect the curve to be smooth above this temperature. The sharp change in slope exhibited by T_{L55} at 4·167° K. is therefore entirely inconsistent with our knowledge of the thermodynamic behaviour of helium-4. From the same curves we may note that with respect to the λ-point anomaly T_{L55} is based on a third-order and T_{55E} a second-order transition. This difference has negligible effect on the temperature scale.

Clement[24] has calculated L_T and C_l using the first and second derivatives of the p–T relation for T_{55E}, together with experimental data of state for the liquid and vapour. The results agree, within experimental uncertainty, with the measured values of these quantities and at the same time differ slightly from the values associated with T_{L55}. Hence, for temperatures below the boiling point, both scales are compatible with our present knowledge of the thermal properties of helium-4.

In making a comparison between any interpolation device, such as carbon and paramagnetic salt thermometers, and a supposed absolute scale, a decision must be made as to which 'tie-down' points are to be used for normalization of the relative measurements. If the absolute scale really were entirely correct, any points would do, provided a sufficient number were taken to determine the unknown constants of the relationship between temperature and resistance (or magnetic susceptibility). However, since we do not have as yet a true thermodynamic scale, it is often best to obtain in some way an average fit. In making such averages we find that the magnetic and resistance data cannot distinguish between the two scales, except as noted earlier in connexion with the resistance data above 4° K. This failure, however, does not detract from the validity of the use of these data for interpolation. I should like to point out that earlier magnetic experiments by Ambler and Hudson[15], which apparently gave a superior fit to T_{L55}, have been repeated[25] and now agree equally well with T_{L55} and T_{55E}.

In the region of the λ-point a comparison of T_{L55} with T_{55E} reveals a subtle yet significant difference. The vapour-pressure of pure liquid helium-4 at the λ-point is measured in relation to the abrupt change in some property of the liquid and is therefore not dependent on any temperature scale. In conjunction with tables of T_{L55} van Dijk and Durieux state this pressure to be 37·67 mm. mercury at 0° C. as determined from the "most accurate Leiden measurements". On the other hand, equations (1) and (2) defining T_{55E} were made to join with continuous $\mathrm{d}p/\mathrm{d}T$ at a λ-point pressure of 37·86 mm. mercury. This figure was arrived at from an average of four recent determinations, including the Leyden value, and those of Long and Meyer[26] (37·96 ± 0·02 mm. mercury), Erickson and Roberts[6] (37·91 ± 0·05 mm. mercury), and unpublished measurements[24] made at the U.S. Naval Research Laboratory. Newer measurements by Dash and Taylor[27] giving 37·86 ± 0·05 mm. mercury substantiate the value selected for T_{55E}. We have no satisfactory explanation for the failure of van Dijk and Durieux to include some of the other data for the selection of a λ-point pressure. Since some of the properties of liquid helium change so markedly at the λ-point, it is often of importance to the experimenter to know on which side of this point his experiment is being conducted; we can imagine his dilemma when he measures a vapour pressure of 37·75 mm. mercury and sees from T_{L55} that the temperature is above the λ-point, whereas according to T_{55E} it is below the λ-point.

Conclusions and Recommendations

Now that the discussion concerning the background of the causes of dissension leading to the 'Battle of the Millidegree' is completed, I propose to assess the relative merits of each side. We cannot permit ourselves to lean back indifferently and consider that the whole affair is a tempest in a teapot, that, after all, what matter a few millidegrees, more or less! Even though both proposed scales represent a considerable improvement over the 1948 scale, we feel that the unfavourable consequences of having two scales must be avoided so far as possible. In theory, each scale is capable of closely representing the true thermodynamic temperature; but we must admit the possibility that neither does in practice; T_{L55} approaches the problem by constructing a non-unique p–T relation from the best available experimental thermal data, while T_{55E} does this from the best available experimental p–T data. We must decide to use the one scale which will best serve low-temperature research until more accurate experimental evidence of both kinds is obtained.

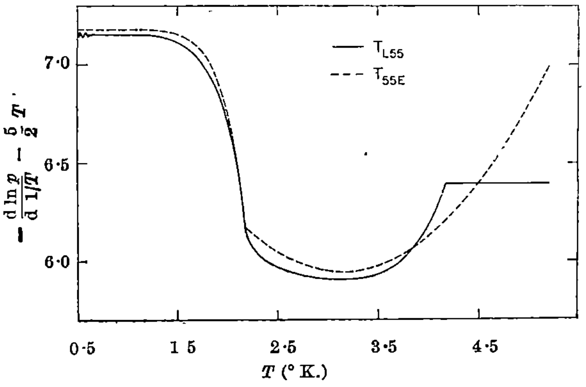

Fig. 2. A plot of $-\mathrm{d}\ln p/\mathrm{d}\,(1/T) - 5/2\ T$ vs. temperature for T_{L55} and T_{55E}

I favour T_{55E} primarily because I believe that it more closely represents actual vapour-pressure–temperature measurements as determined in the laboratory. I feel this is true not only concerning the λ-point pressure and the region between 4·2° K. and 5·2° K., as I have discussed in some detail, but also of the region below 4·2° K. as well. I consider it extremely reassuring that a single equation, such as equation (1), can fit the results of several independent investigators over so wide a temperature range with such a remarkably small mean deviation. In short, if the temperature scale is to be based on the helium p–T relation, I prefer a scale derived from data and procedures which directly match those used in obtaining temperatures in everyday experiments.

It is, of course, very desirable to tie everything up in one package, to obtain with equation (3) a complete thermodynamic description of helium-4 along the saturation curve and thereby arrive at a temperature scale. Above 4·2° K. it is at present out of the question to employ the method of van Dijk since the necessary data do not exist. Below 4·2° K. we have seen that there are uncertainties inherent in the thermal and state data such that an accurate temperature scale can be obtained only through reliance upon experimental p–T data as a guide.

From the above discussion it can be seen that a single scale could have been derived by combining T_{L55} and T_{55E} and retaining the more favourable features of each. Above 4·2° K. it is undoubtedly best to represent the scale with equation (1). Below 4·2° K., equation (3) could be made to fit the experimental vapour-pressure measurements through utilization of the considerable compliance in the thermal and state data (Table 1). This would essentially amount to using the numbers of T_{55E} and the form of T_{L55} without compromising the stated accuracy of any of the pertinent experimental data. Had such a scale been presented in place of the other two, it would have undoubtedly been favourably received; the merger can still be effected, but not without considerable effort. Lacking this reconciliation, we are forced to decide between the form and the numbers. I believe it is safe to assert that cryogenic experimenters attach more importance to the latter. The numbers exist in the tables of T_{55E}, and I recommend that these be used.

The arrival at the above conclusion is not tantamount to a proclamation of victory for either side, for the real question of which scale is overall closer to the thermodynamic scale cannot be answered on the basis of the existing evidence. It does, however, present the more reasonable interim scale for practical use and allows all concerned to withdraw from battle and go about the business of obtaining new information necessary for determining a thermodynamic scale.

I wish to state that, though the above decision was arrived at independently, my confidence in it has been bolstered by the concurrence of the staff members of the Cryogenics Group, Los Alamos Scientific Laboratory, namely, E. F. Hammel, E. R. Grilly, J. G. Dash, R. D. Taylor, R. H. Sherman, E. C. Kerr, A. F. Schuch, T. R. Roberts and S. G. Sydoriak. All the material presented has been thoroughly discussed with these individuals, and, indeed, ideas for some of the arguments given were conceived by them. I am grateful for their help and criticism. In addition, it is a pleasure to acknowledge as a source of information and stimulation helpful discussions with J. R. Clement, R. P. Hudson, E. Ambler, H. van Dijk and M. Durieux. This work was performed under the auspices of the U.S. Atomic Energy Commission.

SCIENTIFIC AND ENGINEERING MAN-POWER IN GREAT BRITAIN

THE recently issued report on scientific and engineering man-power in Great Britain* embodies the results of two related inquiries. The results of the first, initiated by the Ministry of Labour and National Service, and carried out with the help of the Social Survey, which was concerned with the present number and distribution of scientists and engineers, and with the demands of industry and the other main users of scientific man-power in three years time, are set out in the second part of the report. The second study, the conclusions of which are given in the third part, was made by the Committee on Scientific Man-power of the Advisory Council on Scientific Policy and was concerned with the probable trend in the long-term demands for scientists and engineers. Its purpose is to set a goal for the universities and the technical colleges of Britain, so that present and future demands for trained scientific man-power may be met.

---

* Scientific and Engineering Manpower in Great Britain: a Report on the Number and Distribution of Scientists and Engineers now employed in Great Britain, and a Study of the Likely Trend in the Future Demand for Scientific and Engineering Manpower. (London H.M.S O., 1956.) 1*s*. 6*d*. net.

In the present inquiry, the terms 'scientist' and 'engineer' are used to cover the basic sciences on one hand and the applied sciences in the engineering field on the other. The term 'scientist' in this report covers biology, chemistry (other than pharmacy), geology, mathematics, physics, and general science, while the term 'engineer' covers persons with a degree or other professional qualification in chemical engineering, civil and structural engineering, electrical engineering, mining engineering, mechanical, aeronautical and other branches of engineering, and metallurgy. The report thus excludes those who have studied science at the universities but qualified in agricultural science, dentistry, medicine and veterinary science, and it does not include people with specialized qualifications in certain fields of technology such as textiles and rubber. The social sciences are likewise excluded. Its attention is concentrated on the demand for 'qualified' scientists and engineers, and this is taken to mean those with a university degree in these fields or who are associates of certain bodies such as the Manchester College of Technology, or corporate or graduate members of the professional institutions listed.

The Ministry of Labour's inquiry was linked with an inquiry on behalf of the Department of Scientific and Industrial Research into the proportion of industry's resources spent on research. Information was obtained from all manufacturing establishments employing 500 workers or more, and from a samplo of those with between 100 and 499 workers. Establishments with less than a hundred workers were not approached. Slightly different sampling arrangements were used in the building and contracting industry; information was obtained from the boards of nationalized industries, central government departments and local authorities, but agriculture, the non-nationalized parts of the mining and transport industries, shipping, the distributive trades and miscellaneous service industries were not covered.

For early 1956 the inquiry gives the total of qualified scientists as 51,230 and of qualified engineers as 119,700, of whom 32,150 possess higher national certificate or diploma or its equivalent; and of these last, 22,790 are employed in manufacturing industry, 5,330 in nationalized industries (including the Atomic Energy Authority), 1,710 by the central government and 320 by local authorities. For qualified engineers as a whole, the corresponding figures are 37,000, 14,660, 8,050 and 6,330, with a further 2,430 in education; and for qualified scientists, 17,050, 2,420, 5,800, 350 and 25,610. Rough estimates put the number of qualified scientists in other employment at 5,000 and of qualified engineers at 10,000, making a grand total of 134,700. Besides this, there are about 4,700 qualified scientists and 2,300 engineers engaged in postgraduate research at the universities or at present on National Service.

Of the 134,700 qualified scientists and engineers, or about 0·6 per cent of the working population of 24 million, there are thus about 43 per cent in manufacturing industry, 12·5 per cent in the nationalized industries, 21 per cent in teaching, 10 per cent in central government establishments, 5 per cent in local government, and 8 per cent in miscellaneous occupations. Nearly half the qualified scientists are engaged in teaching, and three-quarters of the qualified engineers are in industry.

These scientists and engineers are concentrated in a relatively few industrial groups. Of 48,829 engineers and scientists in manufacturing industry, the numbers were distributed as follows: chemicals (8,300), other plant and machinery (6,700), electrical engineering (12,200) and aircraft manufacture (4,300), accounting for only three-tenths of the labour force, and include nearly two-thirds of the scientists and engineers. While the average proportion of scientists and engineers to the total employed is 0·8 per cent for all industries, it varies widely from one industry to another; from 10·9 per cent for the Atomic Energy Authority (for which the total in 1956 was 2,467, of whom 1,706 were engaged in research and development) to as little as 0·4 per cent in shipbuilding and motor manufacture and less than 0·25 per cent in cotton, wool and wood, cork, paper and printing. Only in mineral-oil refining (5·2), the electricity authorities (2·9), chemical and allied trades (2·7), electrical engineering (2·0), aircraft manufacture (1·9), constructional engineering (1·5), Gas Council and area boards (1·2), non-ferrous metal manufactures (1·1), rayon, nylon, etc. (1·1), and other plant and machinery is it 1·0 per cent or more.

Of the 13,900 scientists and engineers in government service, just over a half are in the defence departments (including the Ministry of Supply), just over a quarter in the Civil departments, and one-sixth in the Department of Scientific and Industrial Research, the Agricultural Research Council, the Medical Research Council or the Nature Conservancy. Of the 6,700 employed by local authorities (other than for teaching) 80 per cent are civil engineers. Of the 25,600 scientists and 2,400 engineers engaged in teaching, 13 per cent are in the universities, and of those teaching in schools more than a quarter are in Scottish schools.

Of those employed in manufacturing industry, about 45 per cent were engaged in research and development, 47 per cent in production, maintenance and installation and the remainder on 'other work', many of whom may not be engaged directly on any form of scientific or engineering work. So far as the figures go, they suggest that well above average proportions are engaged in research and development in the aircraft, electrical engineering, precision instruments, etc., and rayon, nylon, etc., industries, and well below average in shipbuilding and repairing, railway equipment, iron and steel, non-ferrous metal, and other plant and machinery.

Dealing next with the demand for scientists and engineers in the next three years, the report gives the 1959 requirements of industry in Britain at 94,640—an increase of 33 per cent—the increase in manufacturing industry, building and contracting, research associations and nationalized industries (including the Atomic Energy Authority) being given as 37·0, 32·0, 21·0 and 22·0 per cent, respectively. For government departments, local authorities and teaching, an increase of 14·0 per cent for 1959 to 55,400 is reported. For the central government, the increase from 13,850 to 15,850 is mainly in the research departments (23·0 per cent), compared with 12·0 per cent in defence departments and 14·0 per cent in civil departments. For local authorities an increase of 27·0 per cent is reported and for teaching 11·0 per cent, of which 34·0 per cent is estimated for the universities, though this figure is conjectural, being estimated before the University Grants Committee had received the universities estimates for 1957–62.

Among categories of scientists, the greatest numerical increase in the next three years is estimated for chemists (4,500 or 22 per cent), physicists coming next with 2,400 (23 per cent), and mathematicians with 1,500 (13 per cent). For biologists the figures are 600 (12·5 per cent); for geologists, 200 (22·0 per cent); and for other scientists, 300 (11·0 per cent). Among engineers the greatest demand in numbers is expected for mining and other engineers (8,800 or 33·0 per cent), for electrical engineers (5,100 or 23·0 per cent) and for civil engineers (3,400 or 27·0 per cent). For metallurgists the figures are 1,200 (38·0 per cent); mechanical engineers, 1,000 (26·0 per cent); chemical engineers, 700 (47·0 per cent); and for engineers in teaching, 600 (25·0 per cent).

The Committee on Scientific Man-power bases its assessment of the long-term demand for scientists and engineers on the assumption of an overall expansion of industrial output of 4 per cent a year, and that this is only possible if there is an adequate supply of scientists and technologists. This involves assumptions of increases of 7 per cent and 5·25 per cent for the chemical and engineering industries, whereas only 2·5 per cent is assumed for the textile industry. Replies received to the Ministry of Labour questionnaire indicate that, without qualification, manufacturing industry expects to employ 37 per cent more scientists and engineers in 1959 than in 1956; but this figure reflects a considerable margin for current shortages of qualified men. The Committee attempted to isolate this element by assuming that the demand for trained man-power in each industry would, at the least, rise in relation to the number now employed by the same proportion as output is expected to do over the next three years. The difference between this estimate and the figure supplied by industry is taken to represent the presumed current shortage; and an allowance for this factor has been added to the number currently employed, before making the extrapolations based on changes in output over the next ten years. The result is an estimate of the demand for scientific man-power in terms of the number of scientists and engineers necessary to permit an increase in industrial output of 4 per cent per annum.

The estimates for government departments are based on existing policies and allow only for a very modest increase over the next ten years. Sufficient teachers are postulated to deal with the increased number in secondary schools, but not for any further concentration on scientific subjects or for any improvement in existing staffing ratios, for which about four thousand additional science graduates would be a reasonable assumption. Requirements of the universities are assumed to increase by about 100 per cent over the period.

The broad conclusion is reached that an increase of rather more than 60 per cent is required—from about 135,000 to about 220,000 in 1966—the increase for engineers being about 70 per cent and for scientists about 50 per cent. The annual gross flow of those qualified in pure and applied science from the universities and technical colleges is to-day a little more than 10,000—roughly about half scientists and half engineers—and this could well rise to 12,000 by 1958–59. During the next five years, some 60,000 people qualified in science and engineering might come from the universities and technical colleges of Great Britain; but this would have to rise to 16,000 a year if the figure of 220,000 is to be reached by 1966. Allowing 25 per cent for overseas students, emigration, etc., and some continued measure of shortage, the Committee estimates that an annual output of 16,900 in 1966 and 19,900 in 1970 is required.

The Committee recognizes that its estimates involve some margin of error, but it points out that it may well have taken too conservative a view of the demand that is likely to develop in some sectors of the economy. It suggests, however, that the estimates point to a reasonable objective for the universities and technical colleges. In conclusion, the Committee emphasizes that, at the national level, an annual figure of 'graduations' in pure and applied science of about 20,000, as compared with the present 10,000, is the minimum at which we should aim over the next ten to fifteen years, if the economy of Britain is to grow at an acceptable rate.

METALS IN LIVING SYSTEMS

A SYMPOSIUM on "Metals in Living Systems" occupied the morning session on September 3 of Section B (Chemistry) during the recent Sheffield meeting of the British Association. It was opened by Sir Rudolph Peters with a few remarks about the role of metals in a variety of enzyme reactions and the importance of metals for the metabolism of all forms of life. He gave some examples of how the biochemist could elucidate the actual function of a metal in an enzymic reaction. In particular, he mentioned the importance of the complex formation between metals and sulphydryl groups as shown, for example, in the interaction of ferrous iron, cysteine and aconitase, studied in his laboratory by Morrison. Sir Rudolph emphasized the complexity of some of the problems by referring to the recent work on the composition of xanthine oxidase.

Prof. A. Neuberger (London) discussed the structure and biogenesis of porphyrins and related compounds. Simple pyrroles have so far not been found in Nature, with the notable exception of the aminomethyl pyrrole, porphobilinogen, which is an intermediate in the biosynthesis of porphyrins and is excreted in the urine of patients suffering from acute porphyria. Much more widespread—and of the greatest importance in connexion with the present discussion—are the macrocyclic tetrapyrrolic structures found in hæmoglobin, chlorophyll and vitamin B_{12}. Prof. Neuberger first discussed the porphyrins forming part of the hæmoglobin, catalase and peroxidase molecules and the type of resonance found in the porphyrin structure. He then briefly considered the types of bond formed between the central iron atom in hæm and the heterocyclic pyrrolic systems. The interaction between the hæm and protein moiety of the hæm proteins was considered and the various types of isomers arising from changes in the order of the 'outer' substituents of the porphyrin ring were mentioned. Turning to the chlorophylls, Prof. Neuberger pointed out that these contain as the central atom not iron, but magnesium, and also differ from the hæm compounds in the degree of saturation of the heterocyclic system. The work of Linstead and his co-workers on the location of the 'extra' hydrogen atom in the chlorophyll molecule was also mentioned. The third type of macrocyclic pyrrolic structure considered was that present in vitamin B_{12}. In this molecule, as shown by Dr. D. C. Hodgkin and Sir Alexander Todd, the macrocyclic system is reduced to a much greater extent than in porphyrins or chlorophyll, and not all the pyrrolic rings are linked, as in the porphyrins or chlorophyll, by methene bridges. Two of the rings are joined by a direct linkage, giving a dipyrryl structure. In addition, the central atom is cobalt.

Prof. Neuberger then traced the development of recent work on the biosynthesis of porphyrins, starting from the discovery in 1946 by Shemin and Rittenberg that the nitrogen atom of glycine is specifically used in the biosynthesis of porphyrin. He described work done in the department of Shemin and in his own laboratory, work which was mainly based on isotope techniques. The isolation of porphobilinogen by Westall and the elucidation of its structure by Cookson and Rimington in 1953 completed the overall picture. Glycine is condensed with an asymmetrically substituted derivative of succinic acid to give α-amino β-oxoadipate, which loses carbon dioxide to yield δ-aminolævulic acid. Condensations of two molecules of the latter then give porphobilinogen. While the last reaction has been shown to be catalysed by a specific enzyme which has been obtained in a purified form, the initial condensation reaction has not yet been clarified at the enzymic level. Prof. Neuberger mentioned experiments done in his own laboratory which indicated that α-amino β-oxoadipic acid is extremely unstable, and it seems uncertain whether it will ever be made by chemical methods. The possibility exists that this α-amino β-keto acid never occurs as such in the biogenesis of the porphyrin ring. The further changes involved in the conversion of porphobilinogen to the naturally occurring porphyrins were then considered. Experiments of Granick and others indicating that porphyrins are precursors of chlorophyll were then described. Prof. Neuberger concluded by saying that the initial steps in the biosynthesis of the macrocyclic system of vitamin B_{12} are probably identical with those established for porphyrins.

Dr. C. P. Whittingham (Cambridge) spoke on "The Role of Metals in the Green Plant" and started his talk by briefly referring to some nutritional problems met with in ordinary farming and horticulture. For example, potassium is required in more than trace amounts ; but other metals which have recently been shown to be important and which are needed in relatively small amounts are manganese, zinc, copper and molybdenum. The plant physiologist who wishes to find out what part a particular metal plays in the metabolism of a plant may observe the physiological effects which result from either using a deficient medium or the addition of a metal poison, that is, a substance combining with a particular metal or a group of metals. This approach was illustrated by some experiments showing the effects of the addition of such poisons to processes such as photosynthesis, nitrate reduction and respiration in *Chlorella*. Another example was the well-known experiment by Warburg in which the inhibitory effect of carbon monoxide on the respiration of yeast is partially removed by illumination. Since it is known that light of the particular wave-length used can cause dissociation of some iron carbonyl compounds, the experiment provides evidence that at least one step in the respiration is probably catalysed by an iron-containing enzyme.

The characteristics of synthetic or assimilatory processes were then discussed in general terms and compared with those of the catabolic reactions. The former are mainly of a reductive nature, such as the conversion of carbon dioxide to carbohydrate in ordinary photosynthesis, or nitrogen fixation or the assimilation of sulphate or sulphite. The catabolic processes on the other hand, in their overall effect, are oxidative. Dr. Whittingham then discussed the various types of oxidation and considered the role of the cytochromes with particular reference to the valency changes which occur in the iron atom. The term oxidation may mean addition of oxygen to an organic compound, removal of hydrogen or just removal of electrons. In the oxidation of succinic acid there is first a removal of hydrogen atoms which is mediated through a flavoprotein complex ; but ultimately there is transfer of electrons, which is catalysed by the iron–protoporphyrin complex of the cytochromes. The flavoprotein itself is complexed with a metal and transfers equivalents of hydrogen or electrons—one at a time—to the iron of cytochrome. The importance of the metal in this reaction has been demonstrated by showing that the activity of the flavoprotein is largely lost on dialysing it against cyanide. The exact manner with which the metal in the flavoprotein complex functions is still a matter for discussion.

Dr. Whittingham then discussed the oxidations, such as that catalysed by polyphenol oxidase. Reactions of this type are catalysed by copper-containing enzymes which are widely distributed in higher plants, but their biological importance is still largely undefined. This type of oxidation may be only of minor importance, but the view is held by some workers that it may constitute an important method of electron transport and be an alternative pathway to that catalysed by the cytochrome–flavoprotein system.

Some aspects of photosynthesis were then discussed in detail. Dr. Whittingham mentioned the effect of iron deficiencies on the chlorophyll content of plants and he also described some observations showing that a deficiency of magnesium affects photosynthesis not only by reducing the chlorophyll content. It is likely that this is due to the fact that magnesium is an important constituent of several enzymic systems involved in the assimilation of carbon dioxide.

In the past few years evidence has accumulated showing that cytochromes, somewhat different in structure from those of the respiratory type, are also concerned with photosynthesis. Dr. Whittingham suggested that such a cytochrome system may supply a small, but nevertheless essential, part of the energy required to convert carbon dioxide into carbohydrate. He then discussed some recent work which showed that manganese played some part, not in the reduction of water to a hydroxyl-like radical, but in the oxygen-liberating part of photosynthesis. Another metal, molybdenum, is implicated in the nitrate reductase activity of *Neurospora*. Dr. Whittingham also considered a few other enzymic reactions which involve metals, such as the decarboxylation of keto-acids. He concluded with a few remarks about the role of potassium. This metal is required for the activity of the enzymes fructokinase and pyruvic acid kinase. But it is unlikely that the major cause of its nutritional importance is due to the co-factor requirements of these enzymes alone. It appears that a purely chemical explanation of the biological activity of potassium in plants, or for that matter in animals, has still to be found.

Sir Rudolph Peters and the audience warmly welcomed Sir John Russell, who in a short talk described how the recent advances in our knowledge of the deficiencies in trace metals were made partly by intelligent interpretation of mistakes in farming, partly by accident, but to a large extent by the application of spectrographic analysis. He gave some instances such as the important economic effects resulting from the realization that certain soils in Australia and New Zealand were deficient in molybdenum, zinc, cobalt or copper, or in combinations of these. He also described briefly the use of iron chelates in Florida.

Dr. D. P. Cuthbertson, director of the Rowett Research Institute, Bucksburn, Aberdeenshire, had most generously agreed to deputize for Mr. Hedley Marston, the head of the Nutrition Division of the (Australian) Commonwealth Scientific and Industrial Research Organization, who was prevented by illness from attending the meeting. Dr. Cuthbertson surveyed in a masterly manner the importance of metals in the nutrition of plants and, in a more cursory manner, of animals, and emphasized the economic importance of the recent work on the importance of the metal content of soil and pasture for the nutrition of sheep and cattle. In the first place, he directed attention to the very specific requirements for metals of both plants and animals. Thus sodium, which is most important in the electrolyte metabolism of animals, does not appear essential for any plant species studied. Certain plants have a very specific capacity for storing certain metals and sometimes in an unexpected manner; thus, legumes are particularly rich in calcium, deciduous fruits in potassium, and some tropical crops have high contents of manganese. Hickory accumulates aluminium and zinc, and the Brazil nut stores barium. Metallic mercury has been observed in the seed capsules of *Holosteum umbellatum*. Iron, copper and vanadium are found in the respiratory pigments of hæmoglobin, hæmocyanin (Cephalopoda and Crustaceae) and hæmovanadin (Ascidae), respectively. Dr. Cuthbertson then mentioned some of the enzymes which contain metals as essential parts of their structures. Thus iron is present not only in hæmoglobin, but also in catalase, the various cytochromes and peroxidase. Zinc is present in carbonic anhydrase. Copper–protein complexes have been isolated from both animal and plant sources, some of which function as enzymes, such as polyphenol oxidase and ascorbic acid oxidase. In this connexion it is of interest to note that workers in the Rowett Research Institute have demonstrated the presence in herbage of a copper–peptide complex which has a greater biological effect than cupric ions in curing copper-deficiency in rats. Recently it has also been shown that molybdenum forms part of the prosthetic group of the enzymes xanthine oxidase and that of nitrate reductase.

Dr. Cuthbertson next discussed the deficiency diseases which may arise in plants or animals through lack of various metals Lack of magnesium in plants, for example, produces characteristic changes in foliage, and deficiency of this metal is especially serious for fruit trees. Lack of potassium has also been shown to be particularly important for fruit trees. In Australia and New Zealand traces of molybdenum have improved clover production and both there and in the United States the rectification of zinc deficiency has greatly increased the citrus crop. Deficiencies of copper and cobalt have been particularly important for ruminants, and the rectification of such deficiencies in certain areas of Australia and New Zealand particularly has increased agricultural production in certain areas by amounts equivalent in value to many millions of pounds per year. There are also areas in the United Kingdom where grazing ruminants suffer from deficiency of cobalt or copper, and there are certain areas where the growth of horticultural crops—cauliflower in particular—is affected by molybdenum deficiency in the soil. There is now a considerable body of evidence showing the importance of trace-metal interaction—effect of the character of soil and of manurial treatment on the availability of metals to plants. Examples of such antagonism are provided by the interaction of iron and manganese and the observation that a high intake of molybdenum may inhibit assimilation of copper. In conclusion, Dr. Cuthbertson emphasized the interesting relationships which are being uncovered between the identification of metals as constituents of enzymes on the level of biochemistry, the nutritional importance of metals in the nutrition of plants and animals and the application of this knowledge to practical farming all over the world.

EDMOND HALLEY: THE FIRST GEOPHYSICIST

By Sir EDWARD BULLARD, F.R.S.

THE three hundredth anniversary of the birth of Edmond Halley falls this week. When he was born on October 29, 1656, the kinematics of the solar system was understood; but the rest of physical science was little more than disconnected fragments. A few principles or laws, such as the isochronism of the pendulum and Snell's law of refraction, were known, but there was little sign of the immense power and utility of the combination of experiment and systematic theory.

By the time of Halley's death in 1742, all this was changed and a body of knowledge and speculation existed that is recognizably the basis of modern science. It is scarcely an exaggeration to say that a single generation invented the technique, and discovered the content of physical science. What is more surprising, they were, in large measure, conscious of what they were doing. They believed that any fact was worth noting and any natural or industrial process worth investigating. As a young man, at

Oxford and in London, Halley knew all the leading figures interested in this new way of approaching knowledge, and soon became himself one of the best known of them. He was interested in and wrote about everything—mathematics, astronomy, ship's tackle, meteorology, magnetism, diving, archæology, the Chinese language, and how to stop ants climbing trees.

In retrospect the science of the period is overshadowed by Newton's demonstration that the motions of the solar system are a consequence of the principles of dynamics combined with the law of gravitation, and others are apt to be judged by their relation to this achievement. By this test, Halley ranks high as the friend and helper of Newton, who provided the stimulus that led to the publication of the "Principia" and as the developer of Newton's ideas on the orbits of comets. Celestial mechanics was the fashionable subject of the succeeding century and the interest in it has somewhat obscured Halley's other work.

One of Halley's earliest interests was in terrestrial magnetism. At the age of sixteen, while still at school, he made a determination of the magnetic declination at London, finding it to be 2½° to the westward. Twenty years later he collected all the available observations and wrote two papers in the *Philosophical Transactions of the Royal Society* which are remarkable for their insight into the real difficulties of forming a satisfactory theory of the Earth's magnetic field. He correctly followed Gilbert in supposing that the Earth's field is of internal origin, but this led to a difficulty. The change in the declination at London between the earliest measurements in 1580 and those of Halley was 14°, and similar changes were taking place all over the world. He saw that such changes could not be accounted for by movements of magnetized material within the earth without "very wonderful Effects in changing the Axis of diurnal Rotation, and . . . strange alteration in the Sea's Surface, by Inundation and Recesses thereof such as History never yet mentioned". At the same time, the great areas over which the declination had the same sign suggested that the cause was at a great distance from the surface of the Earth. These considerations led Halley to suppose that the causes of the slow variation of the declination lie deep within the Earth, and to suggest that the Earth might possess a magnetized core within a magnetized shell and that the core rotates slowly relative to the shell. He saw that such a hypothesis could account only approximately for the observations and suggested that there might be a series of concentric shells within the Earth each carrying its own set of poles.

This argument and its conclusions come very close to the theories of terrestrial magnetism that are fashionable to-day, except that we can escape the necessity for multiple shells by supposing the core to be liquid and thus to be capable of more complicated motions than the rotation of Halley's solid core.

The interest of the papers is, however, not so much that Halley was largely correct in his arguments and conclusions, as in his approach to the problem. He accepts from the start that this is a complicated subject, that a great many observations are needed and that there is no quick and simple answer. He does not try, as did Bond before him and Whiston after him, to make the observations fit some simple empirical law. He requires the motions and stability of his core to be governed by Newtonian dynamics, but expects that there will be a long period of groping for the relevant factors and that he can only "propose an Hypothesis which after-Ages may examine, amend or refute".

This realization of the complexity of the problems of geophysics is characteristic of Halley, and has only been fully regained in our own day as the tidal wave of observational data has swept away so many tidy generalizations.

Halley had a real delight in collecting observations, discussing them, and devising visual presentations of them. The successive editions of his magnetic charts, with their "Halleyan lines" of equal declination, were used for many years after his death and must have been of great practical value. His wind charts show the trade winds and monsoons with great clarity and considerable detail. In discussing the results he says that, on an Earth covered with water, the north-east and south-east trade winds would doubtless circulate continually all round the Earth, but that on the actual Earth the presence of the land disturbs the regularity of the pattern and produces local phenomena such as the westerly winds of the Guinea coast and the south-west monsoon in India. This approach, with its distinction of a general circulation and local disturbances, is sound enough; but unfortunately the explanation proposed for the general circulation is incorrect. It is surprising that Halley, having studied the winds so carefully, did not anticipate Hadley in realizing the importance of Coriolis forces in atmospheric motions.

Halley's approach to lunar theory is along the same lines. It was known that after a period of 18 years and 11 days the positions and velocities of the Earth and the Moon return very closely to those that they had at the beginning of the period. Halley suggested that after this period, the errors of the lunar tables would repeat themselves, and that after observing for one such period empirical corrections to the tables could be derived and used in the future. He first devised this scheme as a young man, but only seriously started the observations in 1721 when he was sixty-five years of age and he completed the eighteen years of observations two years before his death. The tables were published posthumously in England and in France.

Several other examples could be given of investigations involving the discussion of a large body of data and its reduction to some kind of order; such, for example, as the discussion of the births and deaths at Breslau and the calculation of an annuity table from them. His work on comets involved the calculation of orbits for all those for which sufficient observations existed. In addition to the well-known discovery that some comets are periodic, he noticed that their orbital planes were distributed at random, in sharp distinction to those of the planets. To collect the observations and reduce them must have been a very great task; it is characteristic of Halley that he not only carried the work to completion, but also extracted two major discoveries from it.

Halley's great achievements in theoretical geophysics and in the discussion of observations are the more remarkable when it is remembered that he was also a naval captain, who took a 64-ft. ship southwards to the antarctic ice and also made a detailed survey of the English Channel, and that much of his time was spent in experiments on diving, in the improvement of instruments and in the translation of ancient mathematical texts from Greek, Arabic and Hebrew.

OBITUARY

Prof. Frederick Soddy, F.R.S.

FREDERICK SODDY was born at Eastbourne, the seventh child of his parents, on September 2, 1877, and died on September 22 just after his seventy-ninth birthday, and by his passing we lose a personality at once outstanding and complex. He was educated at Eastbourne College, and although destined to be a student at Oxford he was able to spend a year or more of early student activities at Aberystwyth. After graduation from Merton College, Oxford, in 1898, he considered work in Toronto; but that idea did not come to fruition. He went to Montreal and the very fruitful period of collaboration with Rutherford was commenced, which resulted in the establishment of the concept of the disintegration of the radioactive elements. It is impressive how many experiments connected with thorium and thorium emanation have been shown to be contributory to the formulation of the disintegration concept. In conjunction with Rutherford, he made this most valuable contribution to scientific conception when he was in his middle twenties. It has always been recognized that the conception was a joint effort, and, in so far as his half of the credit is concerned, it indicates a consistent feature in his manner and method of thought. In this he himself in no way minimized the place of imagination and intuition. From Montreal he went to work with Ramsay at University College, London, and from that there came the determination of association of helium and radium emanation.

An interlude of a lecture tour in Australia followed, where his talks illustrated with a quantity of radium drew audiences which were ready to yield very adequate remuneration to the lecturer. By this time the recognition by the University of Glasgow of the need of broadening the basis of chemical teaching enabled him to obtain the position of lecturer in physical chemistry and radioactivity and brought him, in the wider circle of the Chemistry Department, the pleasing and attractive friendship with Cecil Desch, who then occupied a parallel lectureship in metallurgical chemistry.

The years in Glasgow from 1904 to his translation to Aberdeen in 1914 are a very productive period for contributions to advancing science. These years were dominated by three types of activities. First, the very thorough and systematic work in which he purified substantial quantities of uranyl nitrate and then proceeded to measure the rate of growth of radium measured by the increasing quantities of radium emanation. As a series of experimental determinations, they were marked by careful systematic methods.

The second type of work to which he devoted much effort was the development of his technique as a lecturer with an appeal to a general, non-technical audience. He seemed to have the example of Sir William Ramsay in mind, and his "Free" lectures in the Botany Class Room of the University had a wide appeal and helped in a valuable way to disseminate the conceptions involved in the new ideas of radioactivity.

The third major activity was all the work and thought that was involved in the development of the conception of isotopes. Here again his intuitions played a very considerable part, and he was much concerned with the idea that had been evolved in his mind of atoms with different atomic properties, possibly different periods of life and/or different atomic weights, which would nevertheless have the same chemical properties. It was the testing of this concept and its verification that logically led to the αβ displacement law. From this also came the introduction into our language of the word 'isotope'. It was suggested by Dr. Margaret Todd, arising from a discussion that Soddy had in the house of his father-in-law, Sir George Beilby, in Glasgow.

After the work on isotopes there followed contributions on the atomic weight of lead from minerals containing radioactive elements, in conjunction with Hyman, and work on the actinium series, in collaboration with Cranston.

A Nobel Prize was awarded to Soddy in 1921 after his appointment to the Dr. Lee's chair of chemistry in Oxford, which he held during 1919–36. However, by this time he was making few, if any, contributions to scientific knowledge, and his time was devoted to riding various hobby-horses which it is difficult to imagine will ever find a permanent place in the culture of our times. Economic theory, the closest packing of spheres, mechanical means of solving differential equations all occupied his interest; in general, these activities produced results satisfactory to him but unconvincing to the expert.

It was my privilege to be close to him in numerous types of relationship: first of all as a laboratory boy, secondly as a student for graduation, and then as a research student doing postgraduate work. That was followed by a position of University demonstrator to his lectureship. While these stages were progressing, a personal friendship developed which existed until his death. In all these aspects complex emotions were involved—much generosity, some supersensitiveness, some hard hitting, much breadth of outlook. To his laboratory boy, he was kindness itself and his capacity for encouragement and leadership was unbounded. Responsibility was given freely, and when it was taken successfully it was much appreciated by him. To students working for graduation, the impression was of remoteness, and, so far as my knowledge of his three teaching appointments goes, it would be idle to suggest that he was successful. Where teaching classical chemistry was concerned, the students were in general unable to follow his methods of thought. But circumstances were wholly different when it came to postgraduate radioactive work directed to experimental determinations. There he made sure there was ample opportunity for discussion, for question and for answer and in general for complete understanding of the point at issue. For elucidation of ideas in those circumstances he was most patient, and when it came to recording results he required the maintenance of a very high standard for logical presentation and clarity of diction. With his demonstrator during a period of concentration of teaching duties, he shared routine responsibilities, so that time was always available to ensure a degree of continuity of research work.

He was elected a fellow of the Royal Society in 1910, and in 1934 the University of Glasgow conferred on him the honorary degree of LL.D.

He married Winifred Moller Beilby in 1908, and her death in 1936 was a grievous loss to him. She was a woman with sound judgment of character and much common sense. Social occasions in their home contributed much mental stimulus and have left me with the happy impression of many games started with intellectual purpose ending in a riot of discursive and witty conversation.

ALEXANDER FLECK

NEWS and VIEWS

Nobel Prize for Medicine for 1956

THE Nobel Prize for Medicine for 1956 has been divided between Dr. Werner Forssman, of Bad Kreuznach, West Germany, and Prof. Andre Cournand and Prof. D. W. Richards, jun, both of the School of Medicine, Columbia University, New York. The award has been given for their work on the catheterization of the heart and pathological changes in the circulatory system.

Institute of Personnel Management: New Director

MR. LESLIE STEPHENS, principal of Fircroft Working Men's College, Birmingham, has been appointed director of the Institute of Personnel Management in succession to Mr. M. B. Forman, who is taking up an appointment with the Staff Department at the headquarters of the National Coal Board, where he will be mainly concerned with staff planning. Mr. Stephens, who is forty-seven, is a graduate of Hertford College, Oxford, and has taken the business administration course at the London School of Economics. Before going to Fircroft Working Men's College in 1946, he was for seven years with the Factory Department of the Ministry of Labour. He is the author of an Occasional Paper (1956) of the Institute, "Employment of Coloured Workers in the Birmingham Area".

Electronic Computing Laboratory of the University of Leeds: Dr. A. S. Douglas

THE University of Leeds has recently announced that a Ferranti 'Pegasus' electronic digital computer has been ordered for installation in the autumn of 1957, and that Dr. A. S. Douglas has been appointed director of the new electronic computing laboratory within the Department of Mathematics. The 'Pegasus' is a medium-sized general-purpose computer, capable of adding or multiplying at the rate of about a thousand ten-figure numbers per second, and will be used not only for the researches of scientific and technological departments in the University but also for industrial and commercial organizations in the Leeds region which have problems calling for high-speed and complex calculations. Although this will be the first electronic computer to be installed in Leeds, members of the University already have had considerable experience of the use of the machine which has been available for some time in the University of Manchester and which is the prototype from which the design of the faster 'Pegasus' has been developed. During the past four years members of the Chemistry Department at Leeds have solved many difficult problems of molecular structure by means of the Manchester machine, and similarly in the Department of Textile Industries a problem concerning the drying processes in paper mills has been solved, one set of calculations for which took only 36 minutes on the computer compared with the many months of desk calculation formerly necessary. The computer will cost about £50,000, a large part of which is being met by a grant from the University Grants Committee; the University hopes that industrial and commercial organizations interested in high-speed computing will give additional aid.

Dr. Douglas is on the staff of the University of Cambridge Mathematical Laboratory and is a Fellow and Junior Bursar of Trinity College, Cambridge. He will take up his appointment in Leeds in September 1957, and will be available for consultation during the intervening period while the computer is being installed and the laboratory equipped and staffed.

Journal of Technology

THE first number of a new half-yearly *Journal of Technology* was published for the Bengal Engineering College in June. It is regrettable that no statement of editorial policy has been included in this number, although the cover pages include useful and detailed instructions to prospective authors. It is not, however, stated whether the *Journal* is intended to be a medium for the publication of papers from the Bengal Engineering College or whether it is intended to cater for a wider field of authors. On the other hand, it is stated on the cover page that the subject-matter is intended to include original research contributions in science and technology, and this intention is fulfilled in the first number, which includes six papers on original research in electrical engineering, geophysics, civil engineering, applied mathematics and applied mechanics. There are also two letters from the Departments of Chemistry and Metallurgy. The technical standard of the contributions is high, the English is good, except for a few minor points, and there is only a very small number of printing errors. A small page-size, 10 in. by 7 in., has been adopted and columns avoided, while a pleasing contrast has been achieved between the print and the paper. The figures are clearly printed and adequate space has been allowed for these and for the tables. At the end of the number are given about eighty short abstracts of publications in other journals. The value of these would be greatly enhanced if the basis of selection was stated. This is an attractive periodical which deserves to succeed, and which should prove valuable to British readers wishing to acquaint themselves with some of the research work being undertaken in India.

Regional Library Systems of Great Britain

THE function and structure of the regional library systems of the United Kingdom, including a section on the support received from the Carnegie United Kingdom Trust and on the work of the National Committee on Regional Library Co-operation, are described in Library Association Pamphlet No. 2, "The Regional Library Systems" (pp. 71; 7*s*., or 5*s*. to members of the Association; 1956), which is a second edition of the pamphlet that first appeared in 1950. Developments since Mr. R. F. Vollans's report on library co-operation in Great Britain was published in 1952 and current problems are discussed in a final chapter, while an introduction directs attention to certain improvements since the first edition was published, notably the general increase in book funds for public libraries and the diminished number of libraries which are borrowing books that should be available in their own stock. Four subject-specialization schemes and two more modest schemes designed to ensure regional self-sufficiency in current British books have made it easier to meet requests for new books, and the existence of the "British National Bibliography" and gradual improvement in the bibliographical training of library staffs have decreased the number of needlessly inaccurate requests. The basic problems remain, much as depicted by Mr. Vollans, and the pamphlet notes certain respects in which the establishment of regional reference libraries is likely to increase the efficiency of the regional lending-library systems. The necessity for government aid is fully recognized, and, by implication rather than by direct statement, the pamphlet is a further indictment of the Government's inaction in this field and failure to implement the recommendations of the Advisory Council for Scientific Policy. Reference is made to an even more detailed scrutiny of the work of the North Western Regional Library System and of its requirements in that area, which was contained in a report, published this year, by J. F. W. Bryan, L. L. Ardern, G. B. Cotton and A. Glencross.

New Australian Map of the Antarctic

The second edition of the general map of Antarctica on a scale of 1 : 10,000,000, produced by the National Mapping Office, Australia (Antarctic Division, Department of External Affairs, Canberra), has recently been published. The first edition was published in 1939, and comparison of the two maps shows not only that very many more named features have been added to the latest map, but also that much of the previously unexplored coast (a dotted line in the 1939 edition) has now been filled in. This is particularly noticeable in the larger-scale inset of the Australian Antarctic Territory. The map is clearly and well produced in colour; lettering is in blue and black; mountains are lightly etched in brown; and ice fronts are shown with the date of their latest known position. Political boundaries remain the same as in 1939. The map is obtainable in Britain from Australia House, London, price 2*s*.

Long Ashton Research Station : Report for 1955

Steady progress in the major activities of the Agricultural and Horticultural Research Station, Long Ashton, is recorded in its annual report for 1955 (pp. 224+12 plates. Published by the University of Bristol, 1956 ; 15*s*.). Collaboration with the Colonial Office has been further developed by the appointment of two officers, one to work on problems of practical entomology and spraying at centres in the Colonial territories and the other will be concerned with engineering problems. The Section of Pomology and Plant Breeding has so far assembled sixty species towards a working collection of *Ribes* species which will serve as breeding material for improving black-currant varieties. An attempt is also being made to clarify the classification of gooseberry varieties with due regard to the complications caused by widespread virus infection. Experiments have been continued with synthetic growth substances to study their efficiency as thinning agents, for controlling pre-harvest drop and for accelerating ripening in apples. As a result of experiments initiated in 1944, it is suggested that the economic life of blackcurrant plantations, hitherto assumed to be ten years, can be confidently raised to fifteen years under present-day methods of management. Investigations carried out by the Fruit Nutrition Section on the cure of chlorosis of fruit trees by application of iron chelate compounds to the soil have shown that complete recovery from chlorosis during the year of treatment can be obtained by soil application of iron chelates to chlorotic pear trees provided the compounds are thoroughly watered in, or placed near the rooting zone by means of liquid soil injection. It is thought, however, that the method is uneconomic, and it was found that three to four foliar applications per season will also give control of chlorosis. In the Cider and Fruit Juice Section vintage trials of cider and perry varieties have been continued, and a standard method of fermentation combined with sterile bottling has been adopted.

Arterial Arches of Birds

It has long been realized that the arteries near the heart and in the neck of birds vary very widely from species to species. Fred H. Glenny (*Proc. United States Nat. Mus.*, **104**, 463 ; 1955) has discussed the modifications of the pattern of the aortic arch system of birds and their significance. He has made a major contribution to this subject during the past sixteen years and has dissected more than 750 species and subspecies. The present memoir considers not only this work but also all that has been reported previously and what is known of the development of these vessels in birds (not a great deal). In the light of this the author has drawn up a classification of the principal patterns encountered with their sub-divisions, and so by means of a series of letters and numbers is able to express the conditions found in the different species in such a manner as to allow of ready reference and comparison. It may be noted, in passing, that the major division is into those with one or two carotid arteries. In his conclusions, he suggests that the Archaeornithes should be placed in the Sauropsida with the Reptilia, "since mere presence of feathers is not sufficient for placing them in close association with modern birds". As commonly understood, however, the Sauropsida includes Reptilia and Aves as opposed to the Theropsida, the Mammalia. This memoir contains a great deal of information in a concentrated form, and constitutes a mine of information for future reference. The eleven figures contain a large number of individual diagrams, and in view of its usefulness it is a pity that many of them are not larger and clearer. Fig. 108*e* is stated to represent the arteries in *Sphenodon punctatus*, but, so far as can be judged, bears little resemblance to the condition in that animal.

Screens for Meteorological Thermometers

The thermometers used for measuring air temperature and humidity must be at the same temperature as the surrounding air or at the correct wet-bulb temperature. The major source of a difference of temperature between the bulb and the surrounding air is radiation to or from the bulb. A shield must be provided over the thermometers to minimize radiative heat-exchange without impeding the flow of air past the bulbs. The most accurate instrument is the Assmann psychrometer, consisting of two small thermometers, one dry-bulb and one wet-bulb, in narrow parallel tubes made of highly polished metal through which a stream of air is drawn by a fan driven by a clockwork or, better, an electric motor. The Assmann psychrometer is expensive, and the screen most used is the "Stevenson" screen, which is a louvred box painted white and relatively large in comparison with the thermometers which it houses. The Meteorological Service of the West German Republic has recently made experiments (*Ber. Deutsch. Wetterdienst*, **3**, No. 19 ; 1956), to see if a screen cheaper and more easily installed than the Stevenson screen would be satisfactory for use at auxiliary meteorological stations at, for example, farms and in forests. The screens used were four in number : large, medium and small Stevenson-type screens ; and a "shade tube" (*Schattenhulse*) made of polished aluminium foil 0·2 mm. thick, 5 cm. in diameter and 45 cm. long, open at the ends, with a thermometer 32 cm. long fixed along the axis, and suspended so that it could be turned for the tube to be along the wind. The readings of the screen thermometers were checked against those of an Assmann psychrometer. 333 separate trials were made over a period of nearly four months in the late summer and autumn of 1953. It was found that the tube gave the best overall comparison with the Assmann readings, followed by the small screen; then, with an appreciable interval, the large screen; and finally, the medium screen. The aluminium tube came out best under all types of weather and change of temperature. It was best even in calm sunny weather because, though the tube is heated a little above air temperature, the thermometer has better ventilation than the thermometers in the screens, which also are heated above the air temperature.

British Society of Rheology: Officers

THE following have been elected officers for 1956–57 of the British Society of Rheology: *President*, Prof. J. G. Oldroyd; *Honorary Secretary*, N. Wookey (52 Tavistock Road, Edgware, Middlesex); *Honorary Treasurer*, D. W. Jopling; *Honorary Editor*, Dr. E. W. J. Mardles; *New Members of Committee*, C. C. Mell and Dr. J. C. Vernon.

Royal Society of Tasmania: Officers

THE officers for 1956 of the Royal Society of Tasmania are as follows: *President*, Sir Ronald Cross (Governor of Tasmania); *Vice-Presidents*, F. C. Wolfhagen and Dr. W. L. Crowther; *Council*, Prof. T. Hytten, C. Bisdee, Dr. D. Martin, Dr. W. V. Teniswood, Prof. S. W. Carey and L. W. Miller; *Honorary Secretary*, Dr. W. Bryden (Tasmanian Museum and Art Gallery, Box 416B, G.P.O., Hobart); and *Honorary Treasurer*, G. E. Hale.

The Night Sky in November

NEW moon occurs on Nov. 2d. 16h. 43m., U.T., and full moon on Nov. 18d. 06h. 44m. The following conjunctions with the Moon take place: Nov. 4d. 10h., Saturn 1° N.; Nov. 13d. 12h., Mars 7° S.; Nov. 27d. 01h., Jupiter 6° N.; Nov. 29d. 17h., Venus 4° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Spica on Nov. 18d. 18h., Venus being 4·2° N. There will be a total eclipse of the Moon on November 18, partly visible at Greenwich. The Moon enters penumbra at 4h. 00m. and umbra at 5h. 03m.; totality begins at 6h. 08m. and ends at 7h. 27m. Moonset at Greenwich is at 7h. 32m. Mercury is too close to the Sun for observation. Venus is a morning star, rising at 3h. 15m., 3h. 55m. and 4h. 40m. on November 1, 15 and 30, respectively; its distance from the Earth increases from 107 to 123 million miles during the month. Mars is visible during the evenings, setting at 1h. 50m., 1h. 25m. and 1h. 05m. on November 1, 15 and 30, respectively; it continues to recede from the Earth, its stellar magnitude decreasing during the month from −1·3 to −0·4 and its distance from the Earth increasing from 53 to 73 million miles. At the beginning of the month Mars is north of ψ Aquarii, and is moving eastwards, passing into Pisces on November 22. Jupiter rises at 2h. 40m., 2h. 00m. and 1h. 05m. at the beginning, middle and end of the month, respectively, and is near β Virginis; its stellar magnitude is −1·4 and its distance about 550 million miles. Saturn is too close to the Sun for observation, being in conjunction on November 27. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 11d. 23h. 06·6m., 44 Aqr. (*D*); Nov. 14d. 19h. 28·3m., 51 Psc. (*D*); Nov. 22d. 4h. 15·1m., 162 *B*. Gem. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Taurid meteors are active during November 1–16; conditions are expected to be favourable, the radiant is near R.A. 3h. 36m., Dec. 14° N. The Leonid meteors are active during November 15–20, but conditions are unfavourable for observation.

Announcements

PROF. SYDNEY CHAPMAN has been appointed Gauss professor of geophysics of the Academy of Sciences at Gottingen for 1956–57. This professorship was founded in connexion with the celebration of the Gauss centenary. The Gauss professor for 1955–56 was Prof. E. Artin, of the University of Istanbul, who was unable to be in Gottingen during that year, and s also there during the present session.

THE Science Committee of the Society for Cultural Relations with the U.S.S.R. is considering the possibility of arranging a Russian-language school for British scientists to be held in Leningrad during 1957. It would be for scientists with some knowledge of Russian, would be staffed by Soviet teachers, and would last twelve days plus travelling time, six days each way, with hostel accommodation. Sight-seeing would be arranged. The overall cost would be about £80, plus 25 roubles a day spending allowance inside the Soviet Union. Those interested should write to the Society at 14 Kensington Square, London, W.8.

THE Ministry of Agriculture, Northern Ireland, has awarded the following scholarships: *Agricultural Science*, D. L. Armstrong, S. R. J. Bingham, W. M. Dunlop, H. R. Kirkpatrick, D. J. McCormick and J. S. Smith (four years at The Queen's University, Belfast); *Dairy Science*, A. G. Foote (four years at the University of Reading) and R. S. Shannon (two years at the University of Nottingham School of Agriculture, Loughborough); *Forestry*, W. D. Fyffe (three years at the University of Edinburgh), and J. M. Elliott (three years at the University of Aberdeen).

THE Gas Council awards each year five research scholarships to students who have recently graduated in physics, chemistry or engineering, and the scholarships for this year have been announced as follows: R. Salter (Department of Inorganic and Physical Chemistry, Oxford), mechanisms of vibrational activation of hydrocarbon molecules by ultrasonic dispersion measurements on vapours; A. Wint (Department of Chemical Engineering, Cambridge), interfacial transfer phenomena; J. W. Arnold (Department of Chemical Engineering, Imperial College of Science and Technology, London), energy exchange in polyatomic molecules, with particular reference to hydrocarbons; P. Owens (Department of Chemical Engineering, Birmingham), high-pressure reactions between oil and hydrogen; and D. H. Grant (Department of Chemistry, Glasgow), a fundamental chemical investigation within the field of polymer degradation reactions.

ERRATUM. In the communication entitled "Interior Deformation Markings in Copper Fatigue Specimens" by D. S. Kemsley in *Nature* of September 22, p. 653, col. 2, par. 3, line 6, for "632,400 c./min." read "632,400 cycles at 21 c./min.".

TWO NEW NATURE RESERVES IN ENGLAND

THE Nature Conservancy has announced the establishment of the following two new nature reserves in England: Morden Bog, near Wareham, Dorsetshire; and Wren's Nest, Worcestershire.

Morden Bog reserve is about a mile north of Wareham and is close to the Conservancy's research station at Furzebrook. The northern part of the reserve consists of undulating heath and a small pine wood; in the drier parts there is considerable regeneration of Scots pine. In the south of the heath in a shallow lies Old Decoy Pond. The present declaration covers an area of 168 acres and has been made under a long lease from the Drax Estate. The Bog is a unique variant of southern heathland, and carries a rich flora and fauna, both vertebrate and invertebrate. It shares many characteristics with the heaths of Purbeck and the New Forest, including some of the rarities, for example, a grasshopper *Chorthippus vagans* and an ant *Formica picea*, which nests in sphagnum bog. Two of the insects—a digging, predatory wasp *Pompilus rufus* and an ant *Formica pratensis*—are not known to occur elsewhere in Britain. Morden Bog is the most interesting remnant of the great heaths which once stretched from Dorchester to Wareham and were described in Thomas Hardy's novels as "Egdon Heath". Freedom from disturbance and the most stringent precautions against fire are essential for the reserve. Access is by permit only, applications for which should be made to the Conservancy's Regional Officer for the South West at the Furzebrook Research Station, Wareham, Dorset.

The declaration of Wren's Nest as a nature reserve has been made possible by the co-operation of the local authority owning the land, the Dudley County Borough, and negotiations are almost completed with the Coseley Urban District Council for the addition to the reserve of the northern part known locally as Mons Hill. Wren's Nest is internationally famous as a classical geological exposure of Upper Silurian rocks. The Wenlock Limestone (known also as the Dudley Limestone) has yielded a magnificent fossil fauna of probably well over three hundred species, all in a state of perfection such as no other locality in Britain exhibits. This includes the trilobites, shells, corals, sea-lilies and other marine life of the time that the strata were laid down in the sea, which is estimated to be some 330 million years ago. Fossils have been described and figured here since Dr. Plot's work of 1686. Specimens from Wren's Nest are preserved in museums all over the world, and there is a fine collection of them in the Dudley Public Library.

The area is a wooded hill with a broad flattened top (now playing fields) bounded by precipitous and deep artificial ravines which descend into great and steeply inclined caverns. The structure of the hill is a peculiar sharp anticline or arch of the rock strata, which, unlike most anticlines in Britain, can be seen to make a topographical feature. Similar structures are found concealed below ground, protruding into the Staffordshire Coalfield in the north, and Wren's Nest can help in assessing these features. The local limestone was largely won for the iron smelting of the nineteenth century and the early years of the present century. The ravines mark the surface workings, and the deep caverns record the underground exploitation, the limestone being removed by an underground canal which pierces the hill. The reserve is accessible to the public; but permission must be obtained to carry out scientific work, applications for which should be made to the Geologist at the Nature Conservancy headquarters, 19 Belgrave Square, London, S.W.1.

SALT UPTAKE IN PLANTS

THE process of mineral salts uptake by plants is being investigated independently in several laboratories in Britain at the present time. It was appropriate, therefore, that it should be the subject of a session in Section K (Botany) at the British Association meeting this year at Sheffield.

Opening the discussion, Dr. J. F. Sutcliffe (Department of Botany, King's College, London) emphasized the importance of a satisfactory knowledge of the salt relations of plant cells as a basis for an understanding of the processes of absorption and transport in intact rooted angiosperms. His contribution and that of Dr. A. B. Hope (present address: Botany School, Cambridge) were concerned with the mechanism of salt uptake at the cellular level.

From the work of a number of investigators with various experimental materials the following view of salt absorption in a vacuolated plant cell has emerged.

There is an initial uptake of ions by diffusion and exchange through the cell wall and outer protoplasmic membrane into the bulk of the cytoplasm, where they are held by the establishment of Donnan equilibria and by adsorption on to protoplasmic constituents. This physical phase of uptake, which is limited in extent, does not depend directly on an expenditure of metabolic energy. Most of the ions taken into the cell are afterwards transferred across an inner membrane (the tonoplast) and accumulated in a free state in the vacuole. Since the tonoplast is rather impermeable to exchange and diffusion, and, moreover, since movement frequently occurs against a concentration gradient, it is evident that a supply of respiratory energy is involved.

It is generally agreed that active transport takes place by the operation of some form of a 'carrier' mechanism. This probably involves the formation of complexes between the ions and some organic constituents of the cell. These complexes move across the membrane and are broken down on the inner side to release the ions and re-form the original carrier molecules. Although a mechanism of this general kind, with suitable elaboration, will explain the facts that are known about salt accumulation, the precise details of the process have not yet been established. In particular, suitable carrier molecules have not yet been identified with certainty, and it is not clear how energy is incorporated into the system.

Against this background, Dr. Sutcliffe discussed various problems of salt accumulation presented by vacuolated cells of storage tissues. The development of an absorptive ability in cells of dormant organs under the influence of experimental treatments has been related to activation or synthesis of carrier molecules. Recent work of Dale and Sutcliffe (unpublished) has indicated that the inability of freshly cut slices of red beet root tissue to accumulate potassium ions from aqueous solutions of potassium chloride is caused indirectly by the non-functioning of a chloride-transporting mechanism rather than by lack of potassium carriers.

Non-growing cells of storage tissues have a limited ability to accumulate salts and, as uptake proceeds, the rate of absorption diminishes. Evidence has been obtained that this is associated with a decrease in the activity of the transport system rather than to an increase in the rate of outward movement of salt. It was suggested that the final stage in active transport is a spontaneous breakdown of the ion-carrier complex which proceeds so long as the free energy of the system is thereby diminished. With an increase of internal concentration, the complex breaks down less readily, until, when the tissue becomes saturated, all the carrier molecules remain in a combined form, and absorption ceases.

Cells of storage tissues possess the power of discrimination between different ions, and this ability has been examined with respect to the alkali metal ions. In terms of a carrier hypothesis, it is proposed that selective absorption depends on the preferential binding of certain ions by the transporting molecules. This property may prove useful in the ultimate isolation and identification of the substances involved, which is now to be attempted. Preliminary experiments have indicated that particulate fractions from red beet and potato tissues also bind some alkali cations in preference to others, and it seems possible that mitochondria may be a rich source of binding substances similar or identical to those responsible for ion transport in the plant cell.

Dr. Hope discussed fully the processes of physical uptake in vacuolated cells. He raised the question as to which structures in the cell determine the amount and rate of uptake of salts. The cell wall, outer cytoplasmic surface, bulk of the cytoplasm, cytoplasmic inclusions and the tonoplast were considered in turn. Some recent evidence from tracer studies with radioactive isotopes on beet and carrot tissue (Hope, unpublished) indicates the absence of a membrane resisting the exchange-diffusion of ions at the surface of the cytoplasm. It is considered likely that the cytoplasm acts as a Donnan phase with an immobile anion concentration of 100–300 m.equiv./l. The effects of the sign and valency of the supplied ions and the pH of the medium on the equilibrium concentration of ions in such a phase were discussed. It has been established that some ions are bound in cell particles in a relatively non-exchangeable form. This may perhaps be associated with the presence of lipoprotein lamellæ which have been revealed by electron microscope studies. Physical uptake was estimated to account for about one-hundredth of the total inward flux during active accumulation.

Dr. L. J. Middleton (Agricultural Research Council Field Station, Compton, Berks) read a paper on "Interactions in the Transport of Ions through Whole Plants". He said that whereas in studies of salt uptake at the cellular level two phases are commonly distinguished, in intact plants a further process may be examined, namely, the passage of ions into the xylem. There have been some claims that salts may move passively into the conducting elements in the transpiration stream, but the bulk of transport appears to be under metabolic control.

In an experiment designed to discriminate between passive and active movement of salt into the xylem of young barley plants, use was made of the fact that ions are known to compete with one another in the physical and metabolic stages of uptake at the cellular level. Experimental work with disks of storage tissue has shown, for example, that strontium reduces the physical uptake of rubidium, but does not significantly depress the active absorption of these ions. In whole plants, the situation is apparently more complex since results are influenced by the salt status and transpiration-rate of the plant. It seems that salt content is a major factor controlling the gross number of ions absorbed, whereas transpiration-rate is important only when the salt content of the plant is high.

The presence of strontium reduced both the uptake of rubidium and its transport into the shoot in high-salt plants, but had no significant effect in either case with low-salt plants. It was concluded that, in the latter, active secretion of rubidium into the xylem predominates, whereas in high-salt plants physical processes attain some importance.

Finally, Dr. J. L. Harley (Department of Botany, Oxford) spoke on "Factors affecting Salt Uptake by Beech Roots". He suggested that since explanations of the ecological distribution of plants often depend on views concerning their ability to absorb nutrients from the soil, the impact of physiological studies of salt uptake on ecology should be considered. As a phase in research, conditions not met in the field are frequently employed in laboratory work. Convenient temperatures, oxygen tensions and salt concentrations are used rather than ecologically probable conditions. Using results obtained with beech mycorrhizas, sampled from natural habitats, the importance of laboratory work to field studies has been examined.

The effects of a range of temperature, oxygen tension and salt concentration on the uptake of various ions by beech mycorrhizas have been studied. High values of Q_{10} were obtained for uptake over a temperature-range from near zero to 15° C. For potassium concentrations expected in the soil an upper soil temperature of 20° C. limits the condition in which beech mycorrhizas are effective absorbing organs.

Potassium is lost from mycorrhizal tissue into distilled water or dilute solutions containing salts when the oxygen tension falls below 3 per cent. The most efficient absorption of both anions and cations occurs in gaseous mixtures containing 10–20 per cent of oxygen. The oxygen concentration found in the soil horizons in which the roots grow naturally has not been observed to fall below 19 per cent by volume. It may be noted that beech is a plant of dry soils, intolerant of water-logged or heavy soils.

When salts were supplied at a high concentration (10–100 mM) diffusion of ions through the tissues of the mycorrhiza was found to be an important phase in the process of absorption by the host. At low concentrations (0·1–1·0 mM) diffusion of salts through the fungal tissue was negligible. Using a range of phosphate concentration and temperature, and by applying metabolic inhibitors, it was shown that movement of phosphate through the fungal layer into the host plant was probably through the living cells of the fungus, when the material was suspended in dilute solutions.

It was concluded that physiological studies on salt uptake have a contribution to make to ecology, provided that due allowance is made for the differing conditions in the laboratory and in Nature.

J. F. SUTCLIFFE

STATISTICAL MECHANICS OF TRANSPORT PROCESSES

INTERNATIONAL COLLOQUIUM

THE International Union of Pure and Applied Physics arranged a five-day conference at Brussels during August 27–31, which was attended by approximately a hundred scientists who are interested in the statistical theories of irreversible processes. Twenty years earlier, this subject would neither have been worth a conference on its own nor would it have been accredited the title of 'statistical mechanics', which was reserved for the theory of equilibrium. The new name and the attendance of the conference are indications of the progress made within two decades.

The foremost subject of the conference was the problem of reconciling macroscopic irreversibility with the reversible character of molecular mechanics, Newtonian or quantal. The problem is old and its discussion earlier than 1910 is summarized in the famous article by P. and T. Ehrenfest which is even now not out of date. The discussion has only recently gained in importance after the theory of transport processes had increased its scope of validity. In technical terms, the problem put before the conference has the form of deducing the collision equation of Maxwell and Boltzmann or its quantum-mechanical analogue from the Liouville equation or the principles of quantum mechanics, respectively. In considering this subject it was assumed that both, premises and conclusion, are well established, but that the intermediate steps of the deduction are in need of clarification.

It was generally agreed that the validity of the Boltzmann equation depends upon some kind of coarse graining of the distribution in full-phase space. There was, however, no agreement with respect to the method of coarse graining. It was argued that irreversibility is the result of time-smoothing of phase-space distributions and that this process of time-smoothing can and should also be applied in the quantum mechanical theory. An alternative (not necessarily contradictory) view was put forward, according to which irreversibility arises asymptotically in the limit of 'large' time-intervals after motion started from well-defined initial conditions. These are by no means the only current views on the nature of irreversibility; but they can claim the best foundation in molecular dynamics.

It would appear that the main progress in this old discussion consists in replacing guesswork by hard-and-fast mathematical results. It was emphasized in the discussion—very much to the surprise of part of the assembly—that irreversibility is, by necessity, limited to the time interval between two characteristic times, that is, the molecular relaxation or correlation time and the period of a Poincaré cycle.

In the quantum mechanical theory, interest was primarily concentrated on the assumption of 'randomness' which has to be made in the course of the deduction. Whereas previously this assumption was, without questioning, interpreted as the necessity of taking an average with respect to the phases of the wave functions at all times, a somewhat more critical attitude emerged in recent years. In the conference it was shown that the phase-averaging can be avoided and that there are various different ways of deducing irreversibility in statistical quantum mechanics.

Another subject on the agenda concerned the fundamental theory of those transport processes—in particular, processes in liquids and solids—to which the Boltzmann equation cannot be applied. Contributions to this subject were—by its nature—less systematic and of greater originality and perhaps of greater importance for future research. To mention an example, the use in this field of electronic computation was shown; it is employed for solving a cumbersome problem in the dynamics of molecules but assumes peculiar significance as standing half-way between theory and experiment. Whereas measurements of transport coefficients reveal only an average over a large number of samples, the electronic computer produces the samples themselves and shows how their fluctuating properties are smoothed out with increasing numbers.

As another example, the use of elastic rigid spheres as models for molecules should be mentioned. This is apparently a somewhat trivial matter. It was, however, shown that the mathematics of this model have some entirely unexpected features and are likely to be of importance in handling more realistic models of molecules.

Apart from the basis of the theories, the conference had obviously to deal with their application to specific phenomena. So far as transport processes in gases are concerned, this requires appropriate solutions of the Boltzmann equation. A number of papers were read showing that these solutions are not obtained by routine procedures but by careful mathematics and plenty of physical intuition. A wide variety of systems other than gases were considered; contributions included thermal conduction in solids and liquids, relaxation of molecular oscillations, transport of charge and energy by electrons in metals, transport processes in liquid helium, viscosity of electrolytes, fission of uranium and, in some detail, the statistical hydrodynamics of turbulent flow. In these talks and discussions the progress in the theory of irreversibility was demonstrated beyond doubt.

Apart from transport processes, the modern theory of irreversibility is concerned with the extension of thermodynamics to non-equilibrium conditions. During the conference plenty of time and attention were given to the principle of minimum entropy production, which has been widely discussed and would, if fully established, have a wide range of applicability. So far, the significance of this principle has not yet been clarified. Some of the speakers presented deductions of the principle depending upon clear-cut premises; on the other hand, instances were produced in which the principle is not strictly valid. Various alternative aspects of off-equilibrium thermodynamics were presented. Conclusive new results were not offered; but there is increasing interest in the subject. Finally, a fair number of experimental papers were read, largely concerning measurements of the diffusion coefficient or thermal diffusion ratio of mixtures.

This colloquium differed in various respects from meetings of a similar kind. One of its characteristics was the interest shown in the consistency rather than in the result of deductions, an attitude frequently dismissed as 'academic'. Speakers were unanimous in their attempts at clarifying the assumptions underlying their own and other speakers' arguments, concentrating on the physical aspects of the problem and avoiding any form of mathematical pedantry. This again is an exceptional attitude, since there is a widespread habit of adorning dubious physical assumptions with a wealth of good mathematics.

Time provided for discussions was ample; speakers could state their case without any fear of being cut short by a harassed chairman. Discussions were conducted as a free exchange of views, not necessarily perfect views, and without the purpose of scoring debating points. As a consequence, subjects of interest were talked over in their widest aspects and by a large number of speakers, conveying thorough clarification and stimulating ideas to the listeners.

The theory of transport processes emerges from this colloquium as a new branch of statistical mechanics which should have a status comparable with equilibrium theory.

This new branch has to a considerable extent been initiated by the work of H. Falkenhagen, J. G. Kirkwood, L. Onsager, G. Uhlenbeck and J. Yvon, who were among the distinguished visitors attending the colloquium. Its success was largely due to Prof. I. Prigogine, partly in his capacity as organizer and even more by the contributions made by him and his school. Thanks are due to the Université Libre de Bruxelles for hospitality and to the American Air Force for generous help. R. EISENSCHITZ

CHEMICAL ENGINEERING IN THE COAL INDUSTRY

CONFERENCE AT THE COAL RESEARCH ESTABLISHMENT, NATIONAL COAL BOARD

THROUGHOUT the world there has been a renaissance in the application of scientific methods to coal and its treatment. This is not the result of a desire for science for its own sake; but is directly connected with the world-wide problems of energy supply and resources.

A notable feature of this new research work is the increasing application to the coal industry of new chemical engineering techniques developed by other progressive industries. The time seemed ripe, therefore, to bring together the research workers in different countries, from industrial and university laboratories, interested in this new outlook on coal.

An international conference on "Chemical Engineering in the Coal Industry" was therefore organized by the Coal Research Establishment at Stoke Orchard of the National Coal Board. It was held during June 26–29, and was attended by a hundred representatives from Britain and overseas.

Mr. A. H. A. Wynn (scientific member, National Coal Board) in his address of welcome to the delegates, pointed to the fact that all estimates of energy requirements, including those of the U.S.S.R., indicate that the economy of almost every country over at least the next twenty or thirty years will depend fundamentally on the prosperity and technical progress of the coal industry. Mr. Wynn underlined the great variety of coals produced in Britain and the different end-uses to which they are put. It is in the subject of efficient use, particularly of those coals not of the highest quality, that the chemical engineer can play an important part. Some of the economic problems of Western Europe, in his opinion, arise from the insufficient application of modern science to the basic industries.

Three chief problems were considered at the conference: the modification of coal to render it suitable for subsequent processing; the briquetting of coal; and the treatment of by-products resulting from new processes. A remarkable feature of the conference was that, although all the countries represented are interested in these three subjects, their interests are to a large extent directed towards different objectives. Whereas the aim in Great Britain is the production of efficient, solid smokeless fuels, in France the aim is the improvement of metallurgical coke. For both purposes, however, the carbonization of high-volatile coals in fluidized beds shows much promise. Again, there is a parallel of interests in Great Britain and Germany in the production of carbonized briquettes from those coals which are not normally considered suitable for carbonization by traditional methods. In Britain the objective is again the production of smokeless fuels; but Germany considers the process to be promising as a method of producing regular-sized hard coke for metallurgical purposes.

The conference was organized into four technical sessions, which reviewed the following topics: (*a*) the modification of coal properties by oxidation; (*b*) the briquetting of small coal; (*c*) the carbonization of powdered coal in fluid beds; and (*d*) the utilization of the by-products from new carbonizing processes. Papers were presented on both fundamental and technical aspects of these subjects.

Modification of Coal Properties by Oxidation

A paper entitled "The Controlled Oxidation of Coal", which was presented by M. A. F. Boyer (Centre d'Études et Recherches des Charbonnages de France), described some recent work on the rates of oxidation, the activation energies involved, and the depth of penetration of the oxidation reaction into coal particles.

In the production of carbonized briquettes, marked fusion and swelling of the coal is disadvantageous; but these characteristics may be modified or destroyed by a number of methods, principal among which is oxidation. The addition of as little as 1 per cent of oxygen, for example, to the coal can eliminate these adverse effects. However, the fundamental changes which occur on oxidation, particularly the mechanisms of the chemical changes, are as yet not understood. Dr. D. W. Gillings (formerly of the Coal Research Establishment, National Coal Board) pointed out that one effect of oxidation is to decrease the plasticity of the coal. M. Boyer believes this to be an unimportant effect, and considers that the important effect of oxidation is to change the shrinkage characteristics of the coal on carbonization. Dr. J. Bronowski (Coal Research Establishment) pointed out that most explanations have been centred on the amorphous constituent in coal, but that oxygen can also act on the organized graphitic structures in coal, and that further insight into the process should be gained by studying the bonding of these graphitic layers. Mr. E. H. Williams (Coal Research Establishment) directed attention to the fact that the oxidation process may take different courses with different coals, and illustrated his point by showing the differing rates of oxidation in coals of different volatile contents.

The second paper at this session, entitled "Fluidized Oxidation of Coal", concerned the design and operation of a pilot plant for the oxidation of coal at the Coal Research Establishment, and was presented by Dr. G. I. Jenkins. This plant, which operates on the dense-phase fluidized principle, has a throughput of 1 ton per hr. It is composed of four main sections: (*a*) coal grinding and drying; (*b*) hot gas supplies; (*c*) control instruments; (*d*) reactor columns. The plant is fully automatic and is equipped with recording and control instruments for bed temperature, gas flows and temperatures, oxygen concentration of ingoing and exit gases, bed-level and coal feed. Coal has been oxidized at a number of different temperatures up to 400° C., using gases with oxygen concentrations ranging between 10 and 21 per cent. Other variables investigated are distribution of coal-size and contact time. From the results, the heat of the oxidation reaction at a series of temperatures has been deduced and found to be in the range 50 B.Th.U./lb. at 250° C. to 200 B.Th.U./lb. at 375° C. In the discussion, Mr. T. Kennaway (Simon Carves, Ltd., London) described an alternative method of dilute-phase fluidized oxidation, for which he claimed simplicity of construction and of operation. Dr. Jenkins considered, however, that the dense-phase method is to be preferred because it allows more flexibility in the control of variables.

Briquetting of Small Coal

The second session opened with a paper by Dr. W. Reerink (Steinkohlenbergbauverein, Essen) entitled "Investigations into the Carbonization of Briquettes in Germany". The briquettes were designed to replace coke used in blast furnaces and cupolas. In the preparation of the briquettes from powdered coal, use is made of a special binder (*Teerpechschmelze*) applied in liquid form to the coal. This special binder is similar to a 'cut-back' pitch in that it is prepared by adding certain aromatic oils to pitch. Such a mixture, Dr. Reerink claimed, has improved properties of wetting the coal, and hence it leads to a reduction in the weight required. Dr. Kurt Baum (Kurt Baum and Co., Essen), in discussion, emphasized the need to accelerate the carbonization of the briquettes, which at present takes more than five hours. Success in this respect requires the design and adoption of continuous processes instead of traditional batch-wise methods, and attention was directed to work in progress on this subject at the Coal Research Establishment. The potential importance of the use of carbonized briquettes in furnace and foundry work was emphasized. A demand has always existed for a close-sized reactive hard coke for this purpose, and the development of suitable briquettes would meet this.

The Coal Research Establishment's work on briquetting at elevated temperatures was described in a paper by Mr. D. H. Gregory, entitled "Hot Briquetting". This work was undertaken with two objects in view. First, since the briquetting stage may follow one of pretreatment from which the powdered coal is delivered hot, it is possible to conserve heat between pretreatment and carbonization. (It also has the advantage that there is a saving in pitch, because the coal itself becomes plastic and acts partly as a binder at these temperatures.) The second object was the briquetting of chars from fluidized carbonization, and for this purpose the binder used was a coal-and-pitch mixture. This mixture eliminates many of the difficulties experienced in hot briquetting by extending the range of temperature over which the coal remains plastic There is evidence also that the resulting briquettes may be smokeless. A somewhat similar process was described by Ir. G. Kardaun (Staatsmijnen in Limburg, Netherlands), in which a high-volatile coal is used as a binder for a low-volatile coal.

Carbonization of Powdered Coal in Fluid Beds

The first paper read at the third technical session was a joint contribution entitled "A Study of Semi-Carbonization in a Fluid Bed", by P. Foch and A. Peytavy (Centre d'Études et Recherches des Charbonnages de France). This paper described their experience in operating a fluidized carbonizer having a throughput of one ton per hour. The plant has been operated chiefly around two temperatures, 500° C. and 800° C., with the object of producing a char from high-volatile coals, suitable as a blending material in the production of metallurgical coke. The two chief problems outlined by the authors were those of introducing the necessary heat at a rate in keeping with the high throughput of the plant, and of suppressing the entrainment of fine coal and char dust in the gases, where they create acute difficulties in the operation of the by-product recovery system. Mr. J. Owen (Coal Research Establishment, National Coal Board), in discussion, referred to fundamental work carried out at the Coal Research Establishment on the measurement of the heats of carbonization (Millard, D. J., *J. Inst. Fuel*, 28, 345–351; 1955; *Nature*, **174**, 1099; 1954), and described a new method whereby similar results can be obtained from the fluid carbonizing plant itself. The results showed a very steep increase in the endothermic heat of reaction at temperatures between 600° C. and 700° C. Dr. Bronowski followed this up by showing that operation at temperatures around 500° C. and around 800° C. is much more favourable from the point of view of heat requirements than operation in the temperature-range between these values; there the heat requirements are at a maximum near 700° C.

Several speakers emphasized the importance of separation of the entrained dust from the by-product stream, and the wider importance of efficient by-product recovery, since the by-products are of vital importance to the economics of the process.

The second paper presented at this technical session was entitled "The Study of Tars obtained in Fluidized Carbonization", and the authors, Dr. G. H. Watson and Mr. A. F. Williams (Coal Research Establishment, National Coal Board), gave an account of the characteristics of a tar obtained by the low-temperature carbonization of a coal (Coal Rank Code 902) in a prototype 2-in. diameter fluid-bed carbonizer. While not an exhaustive examination (the amount of tar available was only 2 kgm., and examination was complicated by the thermal instability of the tar), the study afforded much information on the constitution of the principal chemical types. In the discussion, Dr. R. J. Morley (Carbonization Department, National Coal Board) pointed out that the constitution of the tar described resembles that of a vertical retort tar, while Dr. H. Bondy (Coalite and Chemical Products, Ltd., Chesterfield) remarked on the differences between this tar and that obtained by the coalite process. Two remarkable features of the tar are that it contains a disproportionate amount of high-boiling phenols and of high-boiling neutral oils.

Utilization of the By-Products from New Carbonizing Processes

Only one paper was read at the final technical session. It was a contribution by J. L. Sabatier (Charbonnages de France, Houillères du Bassin de Lorraine) entitled "Industrial Treatment of Low-Temperature Carbonization Tars". In M. Sabatier's absence, the paper was presented by J. M. Deruelle of the same organization. This paper described the industrial-scale refining of tars obtained from French experimental carbonization plants operating in the temperature-range 500°–700° C. The treatment is conventional and consists of a primary distillation into selected fractions which are further refined by extraction, crystallization or further distillation. The tar yields 10 per cent of phenolic compounds, 60 per cent of oils and 30 per cent of pitch. The principal phenolic bodies produced for marketing are phenol, mixed *m*- and *p*-cresols and 1-2-4, 1-2-5, and 1-3-5 xylenols. Market development is still in progress and will undoubtedly lead to more exhaustive refining of the tar.

In the discussion of the low-temperature tars described, the ease with which the tars may be oxidized to form resinous and pitch-like materials was emphasized, and this was related to earlier papers on the oxidation of coal. This brought out the importance of investigating carbonization techniques in which the heat for carbonization is introduced by methods other than partial combustion of the coal and char in the carbonizing vessel.

Dr. D. McNeil (Coal Tar Research Association) emphasized that the by-products from fluidized carbonization must be the subject of intensive research and that outlets differing from those for conventional tars must be developed.

In his closing address, Dr. Bronowski summarized the discussions and drew some general conclusions. He pointed out that the coal industry, like other traditional industries, is still reluctant to adopt multi-stage processes. The basic cost of handling the raw material in and out of a plant is now so high, however, that an additional stage adds relatively little to the cost of a process. It is essential to base new stages and processes on a scientific study of the fundamental mechanisms by which the chemical and physical properties of coal are changed. The conference showed that all the nations taking part had reached much the same point in these fundamental studies; but they were not all equal in their readiness to take these scientific findings to the pilot scale and to develop them into industrial processes. If we are to benefit from the advances in coal science, we must now concentrate a major effort on development.

The conference was followed by an open day on Friday, June 29, when about 360 guests viewed the experimental work of the Establishment.

EUROPEAN ORGANIZATION FOR NUCLEAR RESEARCH

REPORT FOR 1955

ALTHOUGH much work had already been done by an interim organization, the European Organization for Nuclear Research (C.E.R.N.) came formally into being only in September 1954. The first annual report, covering the period to the end of 1955*, describes in some detail the substantial progress which has been made. It will be recalled that there are twelve member States: Belgium, Denmark, France, the German Federal Republic, Great Britain, Greece, Italy, the Netherlands, Norway, Sweden, Switzerland and Yugoslavia. Each pays contributions roughly according to its national income, the proportions ranging from 23·8 per cent by France and the United Kingdom to 1·79 per cent by Norway. The main aim is to produce those major experimental facilities for pure nuclear research which are too costly for many, if not all, of the member States to provide for themselves, and the present programme includes the design and construction of a 25-GeV. proton synchrotron and a 600-MeV. synchrocyclotron. The governing body is the Council, composed of delegates of member States and assisted by a scientific policy committee with eight members, selected for their qualifications without regard for nationality. A finance committee, with national representation, guides the financial administration.

The present president of the Council is Sir Ben Lockspeiser, and the director-general is Prof. C. J. Bakker, who succeeded Prof. F. Bloch in September 1955 on the latter's return to Stanford University, California. Prof. Bakker's leading collaborators are J. B. Adams (proton synchrotron), W. Gentner (synchrocyclotron), L. Kowarski (scientific and technical services), P. Preiswerk (sites and buildings), C. Møller (theoretical physics) and J. Richemond (administration). The laboratories are under construction on a site provided by Switzerland, at Meyrin, near Geneva. Most of the staff are working in temporary laboratories in Geneva, although a few have already moved to Meyrin. The theoretical physicists are at present centred in Copenhagen. Much of the design of the accelerators and buildings had been established under the interim organization, and the period under review has been occupied in pursuing these plans. The original programme called for the completion of the synchrocyclotron during 1957 and the proton synchrotron during 1960. It is expected to be maintained.

Proton Synchrotron. The main parameters of the large machine were settled at the end of 1954, and no important alterations have been made since. The radius will be 100 m., and the magnet will consist of a hundred separate units with a total weight of steel of 3,200 tons. Protons will be injected at 50 MeV. from a linear accelerator, and the final energy will be 25 GeV. at the maximum magnetic field of 12,000 gauss. The principle of alternating gradient (or 'strong focusing') will be used, each magnet unit having focusing and defocusing portions. This system is now well understood, following much theoretical and experimental work at the Organization and at the Brookhaven National Laboratory in the United States, where a similar machine is being built.

---

* European Organization for Nuclear Research, C.E.R.N. First Annual Report. Pp. vi+66. (Geneva: C.E.R.N., 1955.)

These two projects, which were the first of their kind, are in roughly comparable states of progress, and there has been close collaboration between the two groups. For example, a large electron model, a major project in itself, was built at Brookhaven as an analogue of a large alternating-gradient machine, and the results obtained with it have benefited both projects. There has been interchange of staff between the two laboratories.

The magnet units have to be very accurately made to a design which takes much careful work to establish, and the magnet at Geneva is now completely designed; several full-scale models of individual magnet units were made in order to arrive at a satisfactory solution of the many difficult problems. At the time when the report was written the magnet had not been ordered; but it was expected that tenders would be invited early in 1956. The 50-MeV. injector accelerator is already being manufactured, to a design similar to that of the proton linear accelerator under construction for Harwell. Design of the building and foundations for the proton synchrotron is a major problem. The large magnet ring has to be maintained in a circle and on a plane to within an accuracy of a few tenths of a millimetre, since particle instability is easily induced by misalignment errors when alternating gradient focusing is used. Little was known about such small earth movements over long periods, and prolonged tests were made with an experimental section of ring building, together with much accurate survey work. A method has been adopted whereby a heavy concrete ring is supported by eighty concrete pillars embedded in the rock which lies some distance below the surface. Construction of the ring building is now well advanced, and excavations for the laboratories and experimental hall have been made. The ring building will be mounded over with earth for radiation shielding, and heavy adjustable concrete walls, with beam channels, will be used for separating the experimental hall from the accelerator.

Synchrocyclotron. Most of the design of the 600-MeV. synchrocyclotron had been completed under the interim organization, with Prof. Bakker leading the design team. The magnet, with a pole diameter of 5 m. and containing 2,500 tons of steel, is under construction and was due for completion in August this year. The radio-frequency accelerating system is the most difficult problem in such a large synchrocyclotron. The system adopted is similar electrically to that evolved in Berkeley, California, for the conversion of the 184-in. synchrocyclotron there. The system at Geneva, however, is quite new mechanically, and the tuning-fork type of variable condenser is machined from a solid block of aluminium alloy. This system is also under construction, as are most of the auxiliary pieces of equipment for the accelerator. The heavy fixed shielding-walls have been built, and progress is being made rapidly on the remainder of the building work. Some of the staff of the Synchrocyclotron Division have been working in other laboratories, notably in the Universities of Liverpool and of Upsala, to gain experience of nuclear research with synchrocyclotrons in time for the commissioning of the machine at Geneva.

Other activities. The Scientific and Technical Services Division has been concerned with setting up electronics and mechanical workshops, instrumentation for nuclear research with the accelerators, and library and information services. A limited programme of cosmic-ray research has been started, to help the instrumentation activities to get under way. Design work on buildings had been pursued actively long before the final Organization was set up, and building work was started in 1954. At the end of 1955, 115,000 m.^{3} of earth had been excavated, and 11,000 m.^{3} of reinforced concrete had been set. The Organization has set up its own administrative machinery with its own staff and salary structure, terms of appointment, etc. The total number of staff employed at the end of 1955 was 286, of whom 108 were working on the proton synchrotron, thirty-two on the synchrocyclotron, forty-four on scientific and technical services, six on site and buildings, thirteen on theory, and fifty-nine on administration. These numbers will increase as the work develops. Detailed figures are given for expenditure during 1955, the total being about 18·8 million Swiss francs, or just over £1·5 million. The total expenditure for the first seven-year period is now estimated to be 197 million Swiss francs, plus an allowance of 10 per cent for contingencies.

The report, which is excellently written and produced, shows that the European Organization for Nuclear Research has made very good progress during its short existence so far. It is very encouraging that a co-operative project of such complexity, involving many countries, can be developed so effectively and smoothly. The value of the Organization to science generally, and to scientific progress in the member nations in particular, should more than repay all the effort and expense.

T. G. Pickavance

COMMONWEALTH OBSERVATORY, CANBERRA

REPORT FOR 1955

The Commonwealth Astronomer's report for 1955 on the Commonwealth Observatory, Canberra*, contains nine sections, the first of which, that dealing with time service, and positional astronomy, includes an account of transit observations with the 3½-in. reversible transit circle, which gave 171 determinations of clock error on 170 nights. Other matters referred to are: time signals, which were sent out four times each day, the average correction for the transmitted signal being 29 m.sec.; clock comparisons, maintained as in previous years, reports of which are forwarded to the Bureau International de l'Heure as a contribution to the determination of variations in the Earth's rotation; propagation of radio signals; and lastly, declination of *FK*3 stars. As the Munich observers completed their series of measures of declinations of southern stars with the Munich vertical circle, the instrument has been returned to its native city.

Section 2 of the report covers astrophysical investigations and is divided into various parts, the first of which is concerned with fundamental photometry; Dr. S. C. B. Gascoigne, assisted in the later stages by Dr. W. Heintz, completed the work of comparing the light from a calibrated standard lamp and that from twelve bright stars. This work is further reported under the heading of variable stars, in which Dr. Gascoigne continued the photoelectric observations of brighter galactic cepheids in two colours; the results are in course of preparation for publication, and curves for fourteen are already available. Dr. O. J. Eggen carried out photoelectric observations of short-period variables and discovered variations in four of these. Under the heading of spectroscopy, it is reported that the three-prism spectrograph at the Cassegrain focus of the Reynolds 30-in. reflector has been used for photographing more than five hundred spectra for radial velocity and about a hundred and eighty plates have been measured. This programme includes, *inter alia*, a study of the Scorpio–Centaurus cluster and some southern stars from the *N*30 Catalogue. In work on nebulæ and clusters, the theoretical studies are reported of the former Commonwealth Astronomer, Dr. R. v. d. R. Woolley, assisted by Mrs. D. A. Robertson, on the equilibrium conditions in globular clusters. Mr. A. W. Rodgers investigated obscuration in the Coal Sack region, and red and blue photographs of seven selected representative regions each approximately one square degree in area were obtained; the iris diaphragm photometer was used for measuring about two thousand stars. Under the heading of stellar atmospheres, reference is made to the work of Dr. A. Przybylski in the theoretical investigations on stellar atmospheres, on which he prepared two papers for publication.

---

* Commonwealth Observatory, Canberra. Report of the Commonwealth Astronomer for the Year 1955. Pp. 5. (Canberra: Government Printer, 1956.)

In Section 3, dealing with buildings, grounds and equipment, the installation is announced of three major telescopes on which preliminary tests have been carried out: the 74-in. reflector, the 50-in. reflector which was previously the Great Melbourne telescope, and the 26-in. Yale–Columbia refractor. The first of these was officially opened by the Governor-General of Australia on November 8, 1955, and preliminary tests indicated a certain amount of astigmatism which, Hartmann tests at the prime focus suggest, is related to the method of supporting the primary mirror. The 50-in. reflector, set up as a Gregorian for a few nights for photoelectric observations, has proved satisfactory for this purpose. A plant for aluminizing the mirrors of both reflectors was in the course of delivery. The refractor has been installed, and extensive modifications by the Stromlo workshop have been carried out to such an extent that it has been possible to make preliminary tests. Among other matters referred to may be mentioned the Hilger recording microphotometer which is already in operation, and a spectrograph for use at the Newtonian focus of the 74-in. reflector, received from Carl Zeiss, of Jena.

In Section 4, in which workshop activities are reported, reference is made to the main work on the two reflectors and the 26-in. refractor, all of which have required attention from the electrical, mechanical and optical sections of the workshop. Essential maintenance was performed on telescopes, and mirrors of the 30-in. and 20-in. instruments were aluminized. A Muller-type double-image micrometer has been nearly completed.

The ionospheric prediction service (Section 5) has continued under Dr. W. Baker, and regular publication and exchange of ionospheric data have been continued. Routine measures of ionospheric characteristics were carried out at Canberra, Townsville, Brisbane and Hobart and in Macquarie Island. Dr. G. R. Ellis, working at Hobart, completed the investigations of the *Z* propagation hole in the ionosphere, and in association with Dr. G. Reber observations were made of low-frequency radio emission in the previously unexplored region below 9 Mc./s. Mr. F. E. Cook has continued the forecasting of ionospheric disturbances and has recommenced the observation of sunspots. Special ionospheric reports published include: "An Improved Method of Making High Frequency Radio Propagation Predictions", by J. Turner (Ionospheric Prediction Service *R*5); and "Forecasting of Geomagnetic Disturbances", by F. E. Cook (*R*6). Other sections of the report deal with publications, visiting astronomers and staff.

WEST AFRICAN MAIZE RUST RESEARCH UNIT

In 1949 a rust disease, hitherto unrecorded in Africa, appeared on maize in Sierra Leone. Within three years the disease, which is caused by *Puccinia polysora*, had spread right across the continent and had appeared on islands more than a thousand miles from the east coast. The West African Maize Rust Research Unit, Ibadan, was instituted late in 1952, and the first annual report (1953) of this Unit gives an account of its first year's work. The general background to the problem is given in a foreword by Mr. D. Rhind, the sponsor of the scheme. The Unit is small, being staffed by two scientists, Dr. W. R. Stanton (geneticist) and Mr. R. H. Cammack (mycologist), who have the assistance of a locally recruited technical staff. The main centres of the work are Nigeria and the Gold Coast. The volume of data here accumulated pays tribute to the foresight of the authorities in establishing the scheme, as well as to the energetic activities of those undertaking the work. The three articles from the scientific staff of the unit are backed by a detailed body of information in the form of appendixes.

The plan of the work falls into two sections; first, observations on the course and causes of the epidemic; secondly, the breeding of resistant varieties of maize. The observations on the disease and the associated factors are thorough, and are well tabulated for ease in examination. The record forms an impressive catalogue of the facts that have been considered. The initial spread of the disease, with details of date first recorded in different countries, and with notes on severity and distribution within these countries, is well documented, forming a clear example of the severity with which a new disease may attack and spread. This disease is likely to become a classic to future generations of students of plant pathology. However, purely academic interest is not for long allowed to remain: the economic effects of the disease as quoted appear quite serious. Even before the Research Unit was instituted interim palliative measures, suggested by field observations, were applied, and had somewhat improved the situation. The value of the field observations presented in the report is increased due to the use of a highly standardized, quantitative field assessment method for determining the intensity of rust on a plant or plot, with a minimum of subjectivity. An early observation from plot experiments revealed that intensity of rust was variable with the site of the plot in the territory; this variation in intensity has now been correlated with rainfall and humidity factors. Some further interesting associations are found between time of planting and intensity of rust, time of onset of rust, rate of spread of rust, and yield of the plant. Reduced host vigour later in the season, and increase in potential inoculum of the pathogen, are probably effective in the increased susceptibility of late planted maize. However, fast correlation of disease intensity with specific predisposing factors has not yet been made. Experiments on the effects of host vigour on susceptibility are promised. Such experiments may prove of wide importance, since soils in the maize-growing areas of West Africa, in common with those of other parts of the region, are poor in many of the properties regarded as desirable for the growth of plants. A comparative table of the major differences between *P. polysora* and the more common rust fungus which attacks maize, *P. sorghi*, is presented. This information should help to prevent the confusion between the disease caused by the two species which has apparently been possible in the past. It is shown that the two species differ in the physiology of their urediospores in respect of qualities relevant to infection in this part of the world. The greater virulence of *P. polysora* may be attributable in part to this factor.

The major part of the future work of the Unit would appear to be directed towards the breeding of resistant varieties of maize. So far only the uredial and telial states of the fungus are known: should the rust be truly hemicyclic then there is a high probability of the breeding programme being successful. One appendix to the report gives a list of more than three hundred seed acquisitions originating from most of the world's maize-growing areas. These have been tested under local conditions for resistance to the rust and for yield, and lines from New World sources show a generally high level of resistance. A score of lines promising in several characters, including resistance to other local diseases, have been selected for further work. The report emphasizes that the breeding project aims at a broader end than rust-resistance, the ultimate object of the Unit being to improve on the maize varieties that are currently grown in the region. With this aim in view a comprehensive discussion of the factors affecting maize yields in West Africa is given; in addition to the expected climatic, edaphic and husbandry factors, this discussion includes attention to peculiar local problems such as "elephant and monkey damage". A solution to some of the agronomic and cultural problems discussed here will be invaluable to the future development of the region as a whole.

Although this rust fungus appeared with great suddenness, and found local conditions and host plants favourable for its attack and spread, yet one feels from this report that the problem of the disease is well in hand.

DAVID PARK

ELECTRON SPIN RESONANCE IN MYOGLOBIN AND HÆMOGLOBIN

Orientation of the Hæm Group in Myoglobin and its Relation to the Polypeptide Chain Direction

IN experiments on two crystal forms of myoglobin, Bennett and Ingram[1] have found that the orientation of the hæm groups (one per molecule in myoglobin) relative to the crystal axes can be determined with considerable accuracy by measurements of electron spin resonance. The methods which they used are similar to those described in the following communication on hæmoglobin. They have now extended their investigations to include three further forms of myoglobin crystal (Bennett, Gibson and Ingram, data to be published), and in this paper we shall show how the results can be correlated on one hand with optical measurements of dichroic ratio, and on the other with indications of the predominant polypeptide chain directions derived from Patterson syntheses computed from X-ray diffraction data.

The hæm group contains a planar system of conjugated double bonds. Accordingly, one would expect it to act as a weak absorber of light when the electric vector of the incident (polarized) ray is normal to the plane of the group, and strongly when it lies in the plane. If it were known exactly how the absorption characteristics of a single hæm group varied with direction, then the three absorption coefficients of any myoglobin crystal could be calculated from the orientation of the hæm groups found by electron spin resonance. In the absence of precise data, one must make simplifying assumptions: the results to be quoted here indicate that in the met-form of the protein, it is a fair approximation to treat the hæm group as a two-dimensional circularly symmetrical absorber. It follows that if the direction cosines of the normal to the hæm group are l, m and n (relative to the crystal axes), and if, for example, the crystal is viewed in a direction parallel to c^*, the dichroic ratio is $(1-m^2)/(1-l^2)$ (this result is true for both monoclinic and orthorhombic crystals, the orthogonal axes of reference being taken as a, b and c^* in the former case). Table 1 gives the predicted and observed dichroic ratios for five different crystal forms of myoglobin; in all of them the agreement is satisfactory (except in type D, where the magnetic results are less accurate than the rest, and where the arrangement is such that the calculated dichroic ratio is very sensitive to

Table 1

Type	Species	Space group	Direction cosines of hæm group normals l	m	n	Dichroic ratio			Direction cosines of rod directions l	m	n	Angle between rod direction and hæm normal	hæm plane

the exact orientation assumed). With crystals of derivatives of myoglobin other than met-myoglobin the agreement is much less good; thus the dichroic ratio of imidazole–myoglobin crystals is always less, and that of reduced crystals is always considerably greater, than the values quoted (Kendrew, J. C., and Parrish, R. G., unpublished results). Presumably in these derivatives the absorption characteristics of the hæm group must be more complicated than those postulated above.

We turn now to the question of polypeptide chain direction. Patterson syntheses of a number of crystal forms of myoglobin have been shown to contain rod-like regions of high vector density 10 A. apart[2]. These rods are most clearly visible in a three-dimensional Patterson synthesis of type *F* crystals (Bluhm, M. M., and Kendrew, J. C., unpublished results), in which the orientation of the molecules is particularly favourable, the rod direction being one of the crystal axes. In two-dimensional projections (usually all that are available) the rods are often obscured by other features of the vector structure, and may appear crossed at various angles to one another. However, it is sometimes possible to deduce unique orientations for the rods in (vector) space which are consistent with the features of all three principal projections. It has been postulated that these rods are the vector equivalents of a set of roughly parallel polypeptide chains forming a prominent feature of the molecule. In Table 1 we have listed the direction cosines of the rods deduced in this manner, together with those of the normals to the hæm groups, for all the crystal forms (except type *C*, where the interpretation of the Patterson projections is doubtful). We have calculated the angle between hæm normal and rod direction, with the results shown in the penultimate column. In general, alternative results are obtained, since we do not know which hæm group is associated with which set of rods (the unit cell may contain two or four of each, depending on the symmetry of the crystal). It will be seen that a value of 40–50° is consistent with the results for all the forms (the rod directions cannot be determined within 10°). The complement of this angle is the angle between the plane of the hæm group and the rod direction: the favoured solutions are listed in the last column.

The good agreement between the results for these four crystalline forms suggests that the angle between rods and hæm group is a characteristic feature of the myoglobin molecule even as derived from different species of animal. They suggest also that the rods in the Patterson projections are the vector equivalents of some feature of the molecules which has definite physical reality. If it be accepted that this feature is most probably a set of more or less parallel polypeptide chains, one is led to the interesting conclusion that in myoglobin these chains are oriented at an angle of 40–50° to the plane of the hæm group. Finally, the results for a given form are sufficient to determine uniquely the orientation of the molecules in the unit cell, and are thus a powerful aid in establishing the packing of the molecules in the different forms, a matter which will be enlarged upon in a subsequent publication.

Orientation of the Four Hæm Groups in Hæmoglobin

THE relation between the four hæm groups in hæmoglobin has been a subject of interest and speculation for a considerable time. The initial electron resonance measurements on single crystals of acid-met and fluoride hæmoglobin and myoglobin derivatives[1,2] indicated that the spectra are particularly favourable for accurate determination of orientation, since there is a large variation of *g* value from 6·0 to 2·0 as the applied magnetic field is rotated from a direction in the hæm plane to its normal axis. This variation forms the basis of the present analysis. All that is necessary, in principle, is to discover which crystallographic directions give the minimum *g* value of 2·0, and these are then known to be the directions of the normals to the hæm plane. In practice, the magnetic field is rotated around a convenient crystallographic plane and the orientation of the hæm normals found from the variation of *g* value with azimuth, the *g* value at any angle θ between the plane and the hæm normal being given[2] by $g^2 = 4(1 + 8 \sin^2 \theta)$. In an orthogonal system, it is therefore possible to determine the orientation of the axes from the results in a single plane; but for crystals of lower symmetry measurements in more than one plane may be necessary.

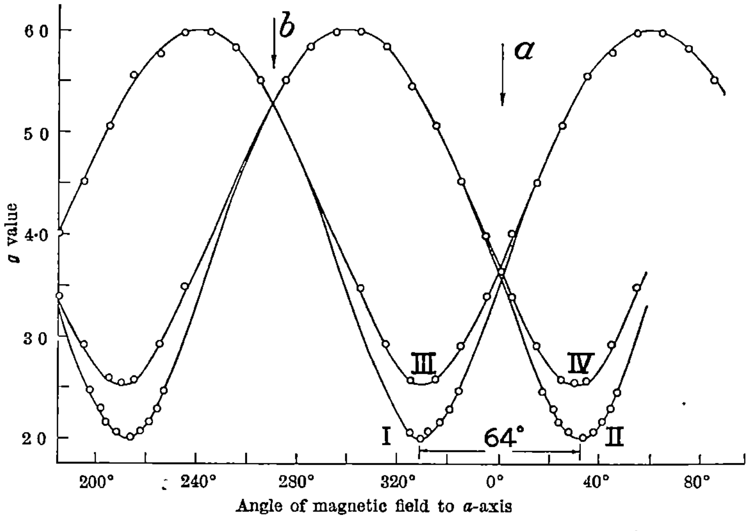

Fig. 1. Variation of *g* values with the direction of the magnetic field in the (001) plane of horse methæmoglobin

The measurements were made at a frequency of 36,000 Mc./sec. and at liquid-hydrogen temperatures, as for the myoglobin crystals[2], and standard methods of detection and display were employed[3]. Horse methæmoglobin crystals were chosen since they present a particularly favourable case. They are monoclinic and belong to the space group $C2$, with only two molecules in the unit cell[4]. The orientation of the two molecules is the same, each being placed on an axis of dyad symmetry. We should thus expect the four hæm groups belonging to each molecule to be arranged in two pairs symmetrically related by a dyad axis. The angular variation of g value obtained with a crystal mounted with the (001) plane horizontal (rotation about c^*) is shown in Fig. 1. All four curves have the same maximum g value of 6·0, since any arbitrary plane will always pass through the plane of the hæm group. Near the high g values the curves coalesce to form two pairs; but they separate near the low g values, showing that different hæm groups are inclined at different angles to the (001) plane. Two of the curves (I and II) are seen to reach the minimum value of 2·0, and hence two hæm normals are immediately located as lying in the (001) plane and at ± 32° to the a axis, which corresponds to the [110] and [1$\bar{1}$0] directions. The other two curves (III and IV) each have a minimum g value of 2·55 ± 0·10, corresponding to $\theta = 16 \pm 3°$. Their hæm normals must therefore enclose an angle of about 16° with the (001) plane, projecting on to it at an angle of 32° to the a-axis. These results are illustrated in a stereogram. (Fig. 2).

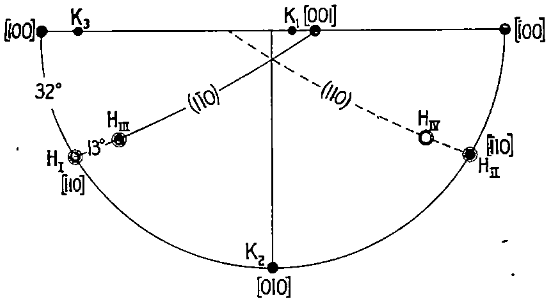

Fig. 2. Stereographic projection showing the poles of the normals to the hæm groups (H) relative to the monoclinic crystal axes. K_1, K_2 and K_3 refer to the principal directions of optical absorption

Another crystal was then mounted on the (110) face. In this case it was found that two of the curves had g values which remained close to 6·0, indicating that their hæm normals enclose a large angle with (110); these would correspond to the normals I and III in Fig. 2. The other two curves, corresponding to the normals II and IV in Fig. 2, both fall to the minimum of $g = 2·0$, showing that these two hæm normals lie in the (110) plane. However, the angle between the two minima is 13 ± 1°, which is more accurate than the angle of 16° deduced from the g value of curve IV in the (001) plane. The angles between the minima II and IV and the [001] and [1$\bar{1}$0] directions were then determined from the orientation of the crystal edges on the (110) face. One of the minima was found to coincide with [1$\bar{1}$0] as expected, and the other to enclose an angle of 13° with [1$\bar{1}$0] in the obtuse angle β. Other crystals were mounted to rotate about the a- and b-axes, with results confirming the above determinations. The orientations of the four hæm normals with respect to the crystallographic axes are therefore as shown in Table 1.

Table 1. ANGLES BETWEEN HÆM NORMALS AND CRYSTALLOGRAPHIC AXES

	a	b	c^*	c
Hæm normals I and II	± 32°	± 58°	90°	108°
Hæm normals III and IV	± 36°	± 57°	77°	95°

Fig. 3 is a perspective drawing in which the members of the two pairs are shown separately and in relation to the external shape of the hæmoglobin molecule[5].

The present measurements place no restrictions on the actual location of the hæm groups along the four normals, nor on their position in space, except that these must conform to the dyad symmetry of the crystal. Many different arrangements are thus compatible with our results. Three alternative kinds are illustrated in Fig. 4. In (a) and (b), the hæm groups are placed near the points of contact between neighbouring molecules in the (001) plane, whereas in (c) they are put next to the SH groups as suggested by Riggs[6].

In the preceding communication, Ingram and Kendrew show that in a variety of different forms of

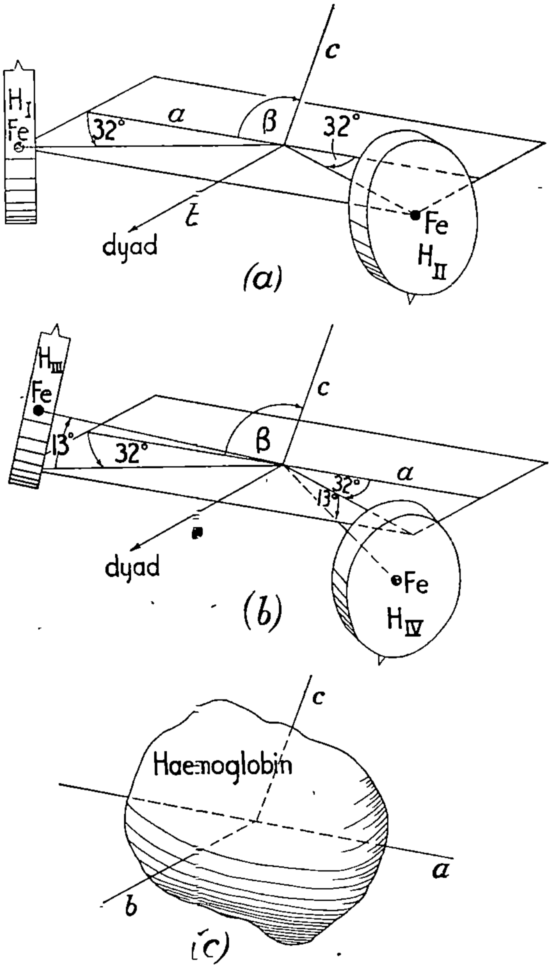

Fig 3. Perspective drawing of the orientation of the hæm groups with respect to the crystal axes and the hæmoglobin molecule. (a) and (b) show the two pairs of hæm groups related by the dyad axis; (c) shows the external shape of the molecule, as determined by Bragg and Perutz (ref. 5), drawn on a much smaller scale than the hæm groups

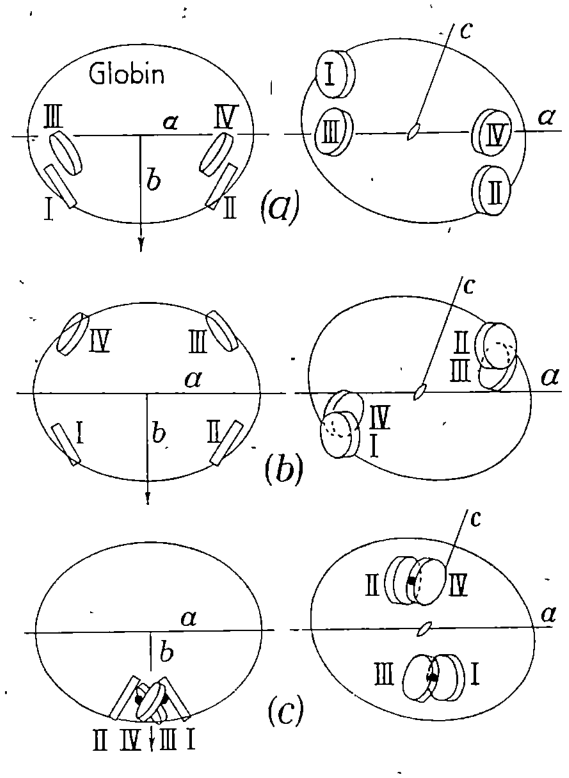

Fig. 4. Three of the many possible arrangements of the four hæm groups in the hæmoglobin molecule, represented diagrammatically as a spheroid. In each pair of drawings the left-hand one shows the molecule in projection normal to the dyad axis, and the right-hand one shows the same arrangement seen along the dyad axis. The small black points in (c) represent the positions of the SH-groups deduced from X-ray analysis

myoglobin the planes of the hæm groups enclose an angle of 40–50° with the polypeptide chain direction deduced from X-ray analysis. In hæmoglobin this angle is somewhat smaller (32° and 36°), so that there is no exact correspondence between the results obtained from the two proteins.

Ingram and Kendrew also show that the polarization dichroism of myoglobin crystals can be predicted from the results of electron spin resonance, by using the assumption that the hæm groups act as ideal two-dimensional absorbers. This calculation is useful both for the intrinsic interest of being able to predict the optical properties of a crystal and also as an independent check on the results—a check which is very sensitive, because the calculated dichroic ratios change by a large amount for a small change in the angles of the hæm normals. Horse methæmoglobin exhibits polarization dichroism of the negative uniaxial kind with dichroic ratios of $K_1/K_3 = K_2/K_3 = 2{\cdot}6$, and with K_3, the direction of least absorption, enclosing an angle of 10° with [100] in the obtuse angle β (Fig. 2)[7]. The results of electron spin resonance should thus allow one to predict both the angular orientation of K_1 and K_3 in the (010) plane and the dichroic ratios. Fig. 2 shows that K_3 lies roughly at the centre of the area marked out by the four hæm normals, which is the expected position; calculation shows that it actually lies within 3° of the predicted angle. The calculated dichroic ratios come to $K_1/K_3 = 3{\cdot}5$ and $K_2/K_3 = 2{\cdot}6$, which is probably as good agreement with the observation as can be expected in view of the simplicity of our assumptions.

It will be interesting to see if electron spin resonance can be obtained from reduced hæmoglobin, which has a different crystal structure and a dichroic ratio[7] of 4·5.

We should like to thank Dr. H. M. Dintzis and Mrs. T. M. Haughton for a supply of very large hæmoglobin crystals.

POSSIBLE ROLE OF GROWTH INHIBITORS IN THE DORMANCY OF SEED OF *XANTHIUM* AND LETTUCE

By Dr. P. F. WAREING and H. A. FODA
Department of Botany, University of Manchester

THE dormancy phenomena shown by the seeds of *Xanthium* species have been the subject of many investigations during the past fifty years[1]. The fruits of *Xanthium pennsylvanicum* each contain two seeds, the 'lower' of which germinates readily after a period of dry storage, whereas the 'upper' seed remains dormant when sown under similar conditions. The dormancy of the 'upper' seed is considered to be due to the relative impermeability of the testa to oxygen, and is generally quoted as the classical example of dormancy due to this cause. Recent experiments by us, however, suggest that the dormancy of *Xanthium* seeds also involves certain germination inhibitors present in the embryo, as well as oxygen effects.

The leaves, fruit-coats and other parts of the plants of *X. pennsylvanicum* have been shown to contain a highly active growth-inhibitor, referred to as 'xanthinin'[2]. Preliminary experiments by us showed that although very little 'xanthinin' appears to be present in the seeds, the latter contain other inhibitors not present in other parts of the plant. These inhibitors from the seeds could not be extracted by solvents such as diethyl ether or absolute ethanol,

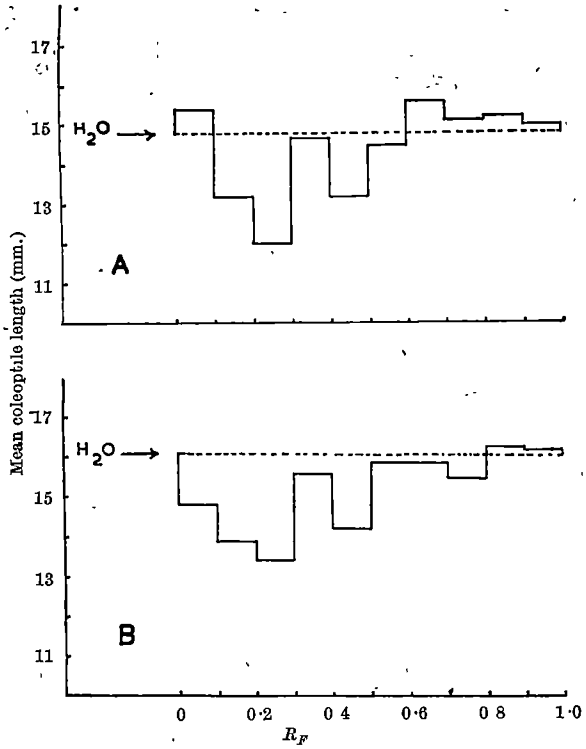

Fig. 1. Growth activity of aqueous extracts of (*A*) *Xanthium* seed and (*B*) lettuce seed, after separation by paper chromatography, using 75 per cent isopropanol + 25 per cent aqueous ammonia (0·88 S.G. × 1/100) as running solvent. Abscissæ: R_F value. Ordinates: growth of 10 mm. wheat coleoptile sections. The dotted horizontal line indicates the growth of control sections in water. Ordinates below this line indicate growth inhibition

but were readily extracted by water or 50 per cent aqueous ethanol. The concentrated extracts were chromatographed on paper, using 75 per cent isopropanol + 25 per cent aqueous ammonia (specific gravity, 0·88 × 1/100) as a solvent. The chromatograms were assayed for growth-activity using primarily the 'straight-growth' method with coleoptiles of oats or wheat. Two highly active growth-inhibiting zones (referred to as *A* and *B*) were found to occur at R_F 0·1–0·3 and 0·4–0·5, respectively (Fig. 1). The high activity of these inhibitors is shown by the fact that an extract of the inhibitor *A* from 1 gm. of seed in 10 ml. of water brings about 58 per cent reduction of growth of the coleoptiles. The *A* inhibitory zone shows a bright green fluorescence, while the second zone *B* gives a blue fluorescence, so that the position of the zones can be determined visually as well as by growth-activity. The *A* and *B* zones were also found to be strongly inhibitory to the growth of cress roots, the germination of lettuce seeds, and the growth of the radicles of *Xanthium*. Most of the growth-inhibiting activity present in the seeds is contained in the embryo itself, and is present in both the cotyledons and the radicle. The inhibitors were found to appear during the later stages of development of the embryo, and to disappear rapidly during germination.

The presence of highly active inhibitory fractions in the embryo raises the question as to whether they may play a part in the dormancy of the seeds. It seemed possible that the presence of the testa may promote dormancy by preventing leaching of the inhibitors from the embryo, apart from any effect it may have on gaseous exchange. This hypothesis is supported by the observation that whereas the inhibitors are rapidly leached out of the isolated embryos by water, very little inhibitory activity can be extracted from the *intact* seeds by leaching. A number of further experiments were carried out to test the 'inhibitor hypothesis'. For this purpose it was found that freshly harvested seeds provided very favourable material. Immediately after harvesting, both upper and lower intact seeds are dormant and cannot be induced to germinate so long as the testas are intact.

An experiment was carried out with two series of freshly harvested seeds, which were soaked in a large volume of water for 48 hr. The testas were removed from one series of seeds before the period of soaking, while the other series was soaked with the testas present. After the period of soaking, the testas were removed also from the second series of seeds. Both series were then sown in Petri dishes under conditions which would preclude any further leaching during the germination test. It was found that the embryos from which the testas were removed prior to soaking germinated readily, whereas those which retained the testas during soaking did not germinate. When the 'leaching' experiment was repeated and the embryos maintained in an atmosphere of pure oxygen after sowing, both series of embryos germinated. This latter result establishes two important points, namely: (1) failure of the unleached embryos to germinate in air is evidently not due to inadequate water-uptake during the period of soaking of the intact seed; (2) when precautions are taken to avoid any leaching after sowing, unleached embryos require increased oxygen tensions for germination even in the absence of the testa. Thus, the requirement of the intact, upper seeds for increased oxygen tensions cannot be ascribed wholly to impermeability of the testa to oxygen. On the other hand, the effect of soaking the isolated embryos suggests that dormancy of the freshly harvested and after-ripened seeds may be removed by the leaching out of water-soluble inhibitory substances, which are prevented from being leached out in the presence of the testa. Determination of the activity levels of the inhibitors in leached and unleached embryos confirmed that leaching does, indeed, result in a marked decrease in the inhibitor-content. Dormancy may thus be overcome either by leaching or by increasing the oxygen supplies to the tissues.

Further experiments were carried out to determine whether the effects of increased oxygen could be related to changes in inhibitor content. It was found that when isolated embryos were maintained in pure nitrogen they remained dormant and the fluorescent inhibitory material in the radicles remained present. When, however, the embryos were maintained in an atmosphere containing sufficient oxygen for germination, then the fluorescent material in the radicles became greatly reduced within a period of 30 hr., before any appreciable radicle elongation could be detected. This observation suggested that the inhibitors may undergo enzymically controlled breakdown in the presence of oxygen. Cell-free extracts were prepared from the radicles of germinating seedlings by extracting the macerated tissue with water, followed by precipitation with acetone. On re-dissolving the precipitate in water, it was shown that the extract was capable of bringing about the rapid breakdown, *in vitro*, of the fluorescent inhibitory material, when mixed with the latter. This breakdown *in vitro* can only occur in the presence of atmospheric oxygen. The activity of the cell-free extract was destroyed by boiling. Cell-free extracts from the leaves of older plants of *Xanthium* were also shown to bring about breakdown of the seed inhibitors. These observations suggest that an oxidase system is present in the tissues, which is capable of bringing about breakdown of the inhibitor in the presence of oxygen. It seems possible, therefore, that the stimulation of germination by increased oxygen tensions is due to a specific effect upon the breakdown of the inhibitors, rather than to an increase in the rate of respiration and general metabolism.

Experiments were carried out to determine whether any difference in inhibitor content could be detected (1) between freshly harvested (dormant) and after-ripened (non-dormant) lower seeds, and (2) between upper (dormant) and lower (non-dormant) *after-ripened* seeds; but no appreciable difference in inhibitor content could be detected as between these various types of seed. It would appear, therefore, that the changes in the depth of dormancy occurring during after-ripening in dry-storage are not primarily ascribable to differences in inhibitor-content, but may involve activation of the enzyme-system which brings about the breakdown of the inhibitors.

There is a close parallelism between the dormancy phenomena occurring in *Xanthium* seed and in those of birch[3] and certain varieties of lettuce. We have found, moreover, that when lettuce seed is extracted and separated by the same chromatographic technique as used for *Xanthium* seed, inhibitory zones appear at the same R_F values as the *A* and *B* inhibitors of *Xanthium* seed (Fig. 1), and show the same fluorescence properties as the latter. By analogy with the phenomena in *Xanthium*, it would thus seem that inhibitors may also play a part in the dormancy of lettuce seed.

It has not hitherto been reported that *Xanthium* seed is light-sensitive; but we have recently found that dormant, intact upper seeds can be induced to germinate if exposed to 18-hr. daily photoperiods of an intensity of 5,000 lux at 25° C. Under 10-hr. photoperiods the germination is much reduced, and the seeds remain completely dormant if maintained in darkness. The day-length effect is enhanced if the seeds are subjected to temperatures alternating between 25° and 18° C. How far this is a true photoperiodic phenomenon requires further investigation. The demonstration that germination of *Xanthium* seed is promoted by light indicates a further resemblance with dormancy effects in birch and lettuce seed.

These studies will be published in detail elsewhere.

GLASSES BASED ON THE OXIDES OF MOLYBDENUM, TUNGSTEN AND URANIUM

By Dr. P. L. BAYNTON, H. RAWSON and J. E. STANWORTH

Research Laboratory, British Thomson-Houston Co., Ltd., Rugby

IN previous publications from this Laboratory, attention has been directed to glasses of unusual composition based on the oxides of tellurium and vanadium[1-4]. This article describes the development of further unusual glasses based on the oxides of molybdenum, tungsten and uranium.

The first stage of the work was to investigate the glass-forming behaviour of melts in a large number of binary systems. A very small quantity (10–20 mgm.) of each mixture was melted in a V-shaped kink in a resistance-heated platinum alloy wire. When the mixture was completely molten it was quenched by switching off the heating current. The melt was observed using a stereoscopic microscope with a magnification of 25. The method will be described in more detail elsewhere.

Binary mixtures of MoO_3 with the following oxides were investigated: Li_2O, Na_2O, K_2O, CaO, SrO, BaO, PbO, ZnO, MnO, Al_2O_3, Bi_2O_3, P_2O_5 and V_2O_5. Glass formation was observed in the systems Li_2O–MoO_3, Na_2O–MoO_3, K_2O–MoO_3 and BaO–MoO_3, the glass-forming compositions containing about 91, 87, 63 and 80 per cent of MoO_3, respectively. These glasses, which were transparent and coloured amber, devitrified very easily and could not be made on a scale larger than 20 mgm. The composition range of glass formation in each system was very narrow—about 5 per cent. Glass formation was also observed in the MoO_3–P_2O_5 system with all mixtures containing more than 11 per cent P_2O_5. These glasses, which were coloured black, did not devitrify easily. Stable glasses can also be made in the system MoO_3–TeO_2, and the properties of these glasses have already been described[3].

Very similar results were obtained in the binary systems containing WO_3. Binary systems of WO_3

Table 1. Compositions of Molybdate and Tungstate Glasses melted on the Scale of 20 gm.

Glass No.	Composition—Wt. per cent						Colour	Thermal expansion coefficient (10^{-7}/°C.)
	WO_3	MoO_3	P_2O_5	BaO	K_2O	Na_2O		
*W*1	75·6	—	20·0	—	—	4·4	Black	74
*W*2	66·7	—	27·4	—	—	5·9	Black	92
*M*1	—	76·5	19·3	—	—	4·2	Black	136
*BM*1	—	57 0	22 8	15·3	—	4·9	Black	145
*PM*3	—	69 6	15·4	—	11 7	3·3	Black	204
*PW*1	71·1	—	11·8	—	14·7	2·4	Amber	180

with the following oxides were investigated: Li_2O, Na_2O, K_2O, Tl_2O, Cu_2O, MgO, CaO, SrO, BaO, PbO, ZnO, CdO, MnO, NiO, B_2O_3, Fe_2O_3, As_2O_3, Bi_2O_3, SiO_2, TiO_2, GeO_2, P_2O_5, V_2O_5, Nb_2O_5, MoO_3. Colourless glasses which devitrified very readily were obtained in the systems Na_2O–WO_3 and K_2O–WO_3, the glass-forming compositions containing about 80 and 82 per cent of WO_3, respectively. Much more stable glasses were obtained in the system WO_3–P_2O_5 with all mixtures containing more than 11 per cent of P_2O_5. These glasses, like the MoO_3–P_2O_5 glasses, were black. A few WO_3–P_2O_5 glasses have been described previously by Rothermel, Sun and Silverman[5]. Stable WO_3–TeO_2 glasses can also be made[3].

Binary mixtures of UO_3 with the following oxides were investigated: Li_2O, Na_2O, K_2O, Cs_2O, CuO, MgO, CaO, SrO, BaO, ZnO, CdO, PbO, B_2O_3, Al_2O_3, SiO_2, GeO_2, TeO_2, P_2O_5, V_2O_5, As_2O_3, Sb_2O_3, Bi_2O_3, Nb_2O_5, Ta_2O_5, Fe_2O_3, NiO, MnO, WO_3 and MoO_3. It was found that the glass-forming behaviour of UO_3 is different from that of MoO_3 and WO_3, in that it more readily forms glasses with acidic oxides. Glasses were formed in the UO_3–V_2O_5 system with UO_3 contents between 20 and 60 per cent. These glasses, which were black, devitrified fairly readily; the most stable glass contained 30 per cent UO_3. Black glasses were also obtained in the UO_3–MoO_3 system with UO_3 contents between 40 and 55 per cent. These glasses devitrified readily and there was considerable volatilization at the melting temperature. Some indication of glass formation was observed in the UO_3–WO_3 system at the composition 50 per cent UO_3, 50 per cent WO_3. Finally, glass formation was observed in the UO_3–TeO_2 system with mixtures containing 10–20 per cent of UO_3; these glasses were yellow. Further small-scale experiments indicated that high percentages of UO_3 could be introduced into sodium borate, sodium silicate and sodium phosphate glasses. UO_3 could be most easily introduced into the Na_2O–P_2O_5 system, and glasses could be made containing up to 40 per cent UO_3.

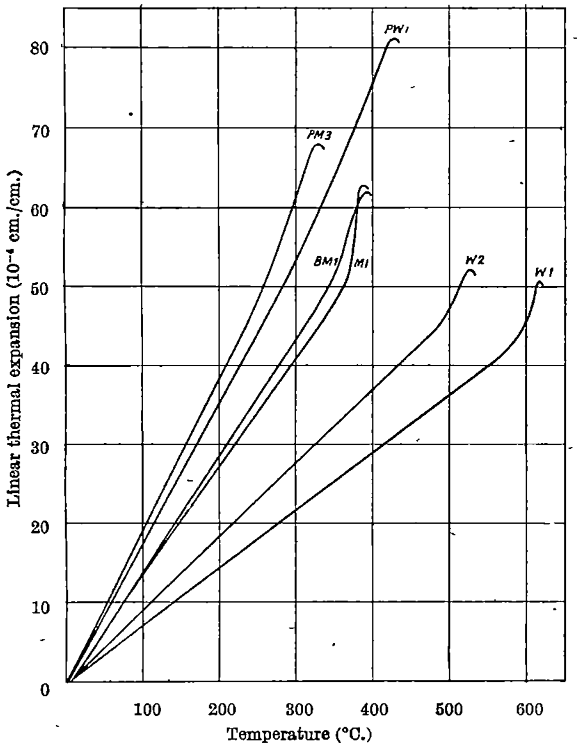

Fig. 1. The thermal expansion curves of some molybdate and tungstate glasses

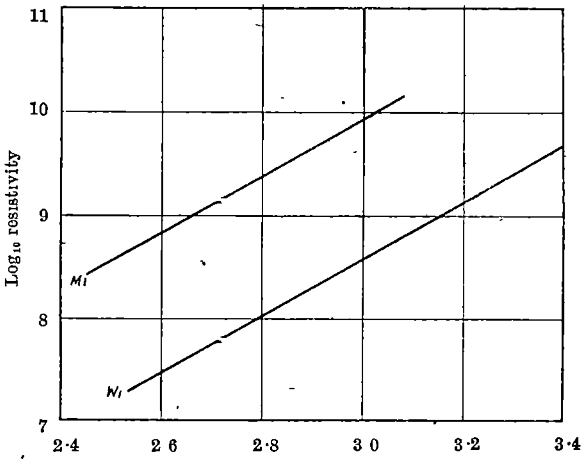

Fig. 2. The change in resistivity with temperature for a molybdate and a tungstate glass.

The K_2O–WO_3, K_2O–MoO_3, BaO–MoO_3 and UO_3–V_2O_5 melts which formed glasses when melted on a scale of 20 mgm. devitrified on cooling when melted on a scale of 1–2 gm. Experiments were carried out to determine whether the glasses could be stabilized by the addition of a third component. By far the most promising results were obtained by additions of P_2O_5, and it was found, for example, that with an addition of 10 per cent P_2O_5 to BaO–MoO_3 melts it was possible to make glasses on the scale of 20 gm. The addition of 5 per cent of P_2O_5 or TeO_2 was sufficient to stabilize melts in the V_2O_5–UO_3 system and glasses were obtained on the scale of 20 gm. Although glasses could not be made even on a 20-mgm. scale in the system WO_3–UO_3, the addition of 5 per cent P_2O_5 gave stable glasses which could be melted on a scale of several grams. An additional effect of adding P_2O_5 was to widen the composition range of glass formation.

The compositions of six tungstate and molybdate glasses are given in Table 1 together with their thermal expansion properties. Thermal expansion curves, and curves showing the change in electrical resistivity with temperature are shown in Figs. 1 and 2. The glasses were melted on the scale of about 20 gm. in silica crucibles at 1,000° C. The black colour and relatively low resistivity coupled with the absence of d.c. polarization effects indicate that the glasses of low alkali contents containing WO_3 and MoO_3 are semiconductors. This is presumably due to the presence of some of the molybdenum and tungsten in lower valency states. No attempt has yet been made, however, to establish the valency state of the molybdenum, tungsten and uranium in these glasses.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Absolute Configuration and Optical Rotation of Folded (α) Polypeptides

Since Pauling and Corey[1] proposed the α-helix for the structure of some folded polypeptides, evidence for the essential correctness of this structure has accumulated; but agreement between the observed X-ray diffraction pattern of oriented fibres and that calculated from the model has not been obtained. As Brown and Trotter[2] have recently shown, with α poly-L-alanine ($(CO.CH.CH_3.NH)_n$), where the scattering centre of the side-chain is fixed with respect to the helix, the agreement along the layer lines is very poor. In this case, the X-ray reflexions can be indexed on a unit cell through which only one chain passes, and it was assumed that both the sense of the helix (right- or left-handed) and the direction of the peptide sequence were identical for all chains. The fit was so poor that it could not be concluded with certainty whether the helices were right- or left-handed.

Since the α-helix conforms accurately to the conditions for minimum energy and also has dimensions which are almost exactly those required to fit the unit cell of poly-L-alanine, it seems likely that the atomic parameters of this helix must be very nearly correct. We have accordingly examined more general arrangements of eighteen-residue, five-turn helices (fibre repeat 27 A.), using the reflecting optical diffraction spectrometer which was described recently[3]. The fibre repeat in poly-L-alanine is longer than this[2], but the effect of the longer repeat on the optical transform is not appreciable. Like-handed hexagonal arrangements of helices which have near six-fold screw axes pack with the observed inter-chain distance whether all chains have the same direction of peptide sequence or not; the necessary condition is that the β-carbon atoms of the methyl side-chain groups should be in identical crystallographic positions. A random arrangement of the direction of the peptide sequence of the individual chains (which is very probable in the absence of strong polarizing forces) will produce the diffraction pattern of a primitive unit cell, though there is, in the strict sense, no unit cell. This arrangement of right-handed helices (corresponding to βC_1[4]) gives diffraction patterns in much better agreement with the observed X-ray pattern than does a left-handed one. The refinement of co-ordinates is not yet complete, but enough has been done to show that satisfactory agreement may be expected with quite minor changes in the co-ordinates originally given by Pauling and Corey[5]. It is most unlikely that any appreciable proportion of left-handed helices contributes to the crystallite reflexions. It is possible, however, that left-handed helices contribute to the observed layer-line streaks; but in this case the proportion would be small. We believe, therefore, that in poly-L-alanine the helices are mainly right-handed, and presumably α-helices of other L-amino-acid polymers will also be right-handed.

The specific optical rotation of an α-helix of poly-glycine (using a very simplified model) has recently been calculated by Fitts and Kirkwood[6]; for right-handed helices this is found to be +132°, in an aqueous solution with index of refraction 1·35. Poly-L-(or poly-D)-alanine is not soluble in non-polar solvents, and since in polar solvents the chains may be random coils (at least at low polymer concentrations) a direct measurement of the specific rotation of an α-helix of poly-L-alanine cannot well be made. However, a *meso* polymer containing a small proportion of one enantiomorph is slightly soluble in chloroform. From measurements on such material, the specific rotation of poly-L-alanine is about +50°, which is considerably less than the figure given by Fitts and Kirkwood for a right-handed helix without active side-groups. Unless their estimate is grossly in error, it would appear that the contribution of the side-chain opposes the form optical rotation of the helix. This would account for the generally low value of the specific rotation of polypeptides in conditions which favour the α-helix form. Fitts and Kirkwood[7] have recently, from similar considerations of optical rotation, also concluded that α-polypeptides form right-handed helices.

An Improvement of the Hydrazine Method for Determination of C-Terminal Amino-acids

Hitherto, investigators using the hydrazine method of Akabori and co-workers[1] found it necessary to treat the peptides or protein with anhydrous hydrazine at not less than 100° for about 10 hr. in order to break all peptide bonds[2-4]. This severe treatment causes complete decomposition of cysteine, cystine and poor yields of arginine, aspartic acid and glutamic acid, with the result that they cannot be determined satisfactorily as C-terminal amino-acids. It is now shown that by the addition of an acid catalyst it is possible to decompose peptides under much milder conditions so that all the common amino-acids can be recovered in fair yield.

About 10 mgm. peptide or amino-acid and 26 mgm. $N_2H_4H_2SO_4$ were dried for about 3 hr. at room temperature under vacuum conditions (about 10^{-4} mm. mercury), 0·2 ml. 100 per cent N_2H_4 distilled in, the tube sealed, heated at 60° for 16 hr. and the excess hydrazine evaporated off over concentrated sulphuric acid in a vacuum desiccator. The residue was dissolved in about 1 ml. dilute hydrochloric acid, shaken with 0·4 ml. benzaldehyde for 2 hr., the aqueous solution separated by centrifugation and dinitrophenylated by Levy's method at 40° in $M/2$ carbonate buffer[5,6]. The aqueous solution (about 8 ml.) was extracted with ether (4 × 5 ml.), acidified with hydrochloric acid and extracted five times with 5 ml. ethyl acetate. The dinitrophenyl-amino-acids and unchanged peptides were separated by one-dimensional paper chromatography using the toluene, phosphate and *t*-amyl alcohol solvents[7]. (With lysozyme it was necessary to remove the dinitrophenol by vacuum sublimation at 40° prior to one- and two-dimensional chromatography). The spots were cut out, eluted with 1 per cent sodium bicarbonate and the optical density measured at 360 mμ (385 mμ for dinitrophenyl-proline) with a Unicam spectrophotometer. These values were converted to percentage yields (accuracy ± 10 per cent) using the results from dinitrophenylation, extraction and chromatography of each amino-acid or peptide separately.

From Fig. 2 it is clear that the hydrazinolysis of DL-leucylglycine is virtually complete after 16 hr. at 60° in hydrazine containing 1·0 *M* hydrazine sulphate but requires 80° for 16 hr. in the absence of catalyst. Since the yields of glycine are approximately the same by both methods (see Fig. 1) the milder acid-catalysed reaction is of no advantage in this particular case. However, it is to be preferred in general because of the greatly increased stability of some of the amino-acids at 60°. From Table 1 it is clear that all the reactive amino-acids, except tryptophan and histidine, are recovered in much better yields, particularly arginine, aspartic acid, cysteine, cystine and glutamic acid. A number of peptides are included to show the application of the method in this field. A 45 per cent yield of leucine was obtained from lysozyme (molecular weight 14,900), and further work on proteins, which is now in progress, will be reported later.

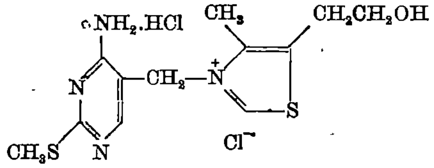
A New Antagonist of Thiamine

4-AMINO-5-hydroxymethyl-2-methylthiopyrimidine[1,2] (I) is an inhibitory antagonist of the pyrimidine moiety of vitamin B_1 (II)[3]. However, a thiamine-requiring mutant of *Escherichia coli* (strain *M*70–17) which can use II for growth will grow in the presence of I if the thiazole moiety of thiamine is also supplied. One possible explanation of this is that, under these conditions, the pyrimidine I is being converted to a functional thiamine-like compound. Consequently, it was decided to synthesize the thiamine analogue derived from I, which would differ from thiamine only in the nature of the 2-substituent, and



III

which, on the basis of a recently proposed mechanism of thiamine action[4], might be expected to have thiamine activity.

4-Methyl-5-(β-hydroxyethyl)-N-(4-amino-2-methylthiopyrimidyl-(5)-methyl)-thiazolium chloride hydrochloride (III) was synthesized by standard methods[5] from I, and its analysis was found to be satisfactory. Instead of replacing thiamine as a growth factor, III was found to be an inhibitory antagonist of thiamine in *E. coli*. The molar ratio of competition (inhibitor/thiamine) was of the order of 100 at concentrations which gave 50 per cent inhibition of growth. Thus, growth of strain *M*70–17 obtained with 0·0001 μgm./ml. of thiamine was inhibited 50 per cent by 0·01 μgm./ml. of III and 100 per cent by concentrations over 0·1 μgm./ml. An increase in the concentration of thiamine required a proportional increase in the concentration of III to give the same level of inhibition.

The corresponding 2-ethylthio compound has been tested on *Amoebae* and is inactive[6]. It would appear that enzyme systems have much more specific structural requirements than the chemical system studied by Breslow[4].

In view of recent work on the metabolic interaction of vitamins B_1 and B_6 [7], it may be of interest that the pyrimidine I has also been found to be an antagonist of pyridoxine[3].

This work was supported by grants from the U.S. Public Health Service. It is hoped to publish full details elsewhere.

Factors favouring Restriction to 1,2 Glycols of Materials coloured by the Periodic Acid–Schiff Reaction

While periodate oxidation was reported first as a histological method for the demonstration of mucin[1], subsequent studies showed its utility for the colouring of glycogen[2] and other carbohydrates or carbohydrate-containing materials[3] in tissue sections. In its present histochemical use, periodate oxidation of tissue sections produces aldehyde presumably from certain specific linkages, chiefly 1,2 glycols and amino, alkyl-amino or ketone substituents of 1,2 glycols. The aldehydes produced by periodate oxidation are coloured with Schiff's reagent.

The initial confidence that only materials containing large numbers of 1,2 glycol linkages, presumably carbohydrates, were being coloured by Schiff's reagent after periodic acid (the PAS reaction[4]) was somewhat tempered by the fact that serine, threonine and 'hydroxylysine' would produce aldehyde after periodate oxidation[5] and quite possibly give a positive periodic acid–Schiff reaction. It was soon indicated that the susceptible linkages would not be available for oxidation in the polypeptide chain of the usual protein molecule and that only terminal serine, threonine and hydroxylysine would be expected to produce aldehyde on periodate oxidation[3]. Since the original publications on periodate oxidation in histochemistry, a number of relevant studies have appeared in the chemical literature without particular notice by histochemists. These are sufficiently important to be mentioned in this communication. The whole subject of periodate oxidation in histochemistry has been reviewed *in extenso* in a separate publication.

The originally described solution of periodic acid for histochemistry, and that which is most commonly used, is 0·5 per cent in distilled water. This has a molarity of 0·022 and a *p*H of 2·1 [6].

α-Glycols, hydroxyaldehydes, hydroxyketones and diketones are oxidized fastest in a slightly acid medium (*p*H 3–5)[7], while α-amino alcohol, amino aldehydes, amino ketones and diamines require a neutral or slightly alkaline medium (*p*H 7–8) for optimal oxidation-rate[8]. The hydroxyaldehydes, hydroxyketones, diketones, amino aldehydes and amino ketones would be expected to produce a coloration with Schiff's reagent without prior periodate oxidation. The diamines and α-amino alcohols do not react rapidly at the *p*H present in 0·5 per cent aqueous periodic acid. Dyer[8] points out that "simple and unhindered α-glycol and α-amino alcohol groupings will be nearly completely oxidized in 5–10 min. at their *p*H of optimum reaction if a moderate excess of periodate is present". The conditions of histochemical periodate oxidation, with a section on a glass slide immersed in a container of the oxidant solution, guarantees an excess of oxidant. The oxidation time originally used was two minutes, now it is five minutes. Dyer indicates further that periods of time longer than 5–10 min. are required for the oxidation of α-hydroxyaldehydes, α-hydroxyketones, α-ketoaldehydes, α-diketones and the corresponding amino derivatives. So long ago as 1941, Van Slyke, Hiller and MacFayden[10] had reported that excess of free periodic acid was associated with slow and incomplete reaction with hydroxylysine and serine.

These data from organic chemistry concerning the influence of time, excess of reagent, *p*H and molarity on periodate oxidation reinforce the belief that materials colouring with Schiff's reagent, presumably aldehydes, which are produced in tissue sections by 5 min. oxidation with 0·5 per cent periodic acid, in all probability consist of, or contain, 1,2 glycol groups and are presumably carbohydrates. Observations to the contrary, that materials of known carbohydrate nature do not give a positive periodic acid–Schiff reaction, and notably that of Jeanloz[11] with cellobiose, can be explained, as pointed out by McManus and Hoch-Ligeti[12], by technical difficulties such as the aldehyde-blockade produced by the use of bisulphite after periodate oxidation.

Effect of Carbon Dioxide Inhalation on the Blood-Brain Barrier

The trypan blue test has been used for studies of damage to the blood-brain barrier caused, for example, by carbon monoxide[1]; but so far as can be seen from the literature no investigation has been carried out on the effect of carbon dioxide on the barrier. Histopathological changes after prolonged exposure to carbon dioxide have been reported by Stephens[2]. They consisted mainly of swelling, chromatolysis and vacuolation of nerve cells.

The present experiments were performed on rabbits which were exposed to various concentrations (10, 15, 20 and 30 per cent) of carbon dioxide in oxygen in a gas chamber. The exposure times varied from 2 to 60 min. Ten minutes before the exposure a trypan blue solution was injected intravenously. Ten minutes after the exposure the animals were killed and their vessels were washed out with normal saline followed by a 20 per cent formalin solution for fixation. On serial frozen sections the whole brains were examined for blue stainings and hæmorrhages.

30 per cent carbon dioxide for 2 min. scarcely caused any obvious changes; but already after 3 min. exposure more consistent changes were seen. After 4, 5 and 10 min. exposure the changes were more pronounced, consisting of marked multiple stainings as well as multiple hæmorrhages. After 15 min. or more the changes often were maximal. Some of these brains were almost totally blue, and there were rich hæmorrhages in the brain substance and the meninges.

In animals exposed to the lower concentrations of carbon dioxide the changes were proportionally less pronounced and occurred only after a somewhat longer exposure. However, still with 10 per cent carbon dioxide and 15 min. exposure clear changes were seen.

The damage to the walls of the blood vessels obviously was reversible within a short time, which was shown by the fact that when trypan blue was injected a few minutes after the gas exposure, the stainings were only slight and the hæmorrhages were unstained.

It may be questioned whether the cause of the barrier damage was a vigorous dilatation of thin-walled vessels or may be a direct toxic effect on the endothelial membranes. The results indicate that hypercapnia is a factor that should not be disregarded as a cause of cerebral damage, for example, in asphyxia, where the component of anoxia sometimes seems to have been over-emphasized.

A detailed account of this work is to be published elsewhere.

Nature of Reticulin

For a long time there has been confusion in the use of the name 'reticulin' to describe the argyrophilic fibrous structures present as basement membrane in the parenchymatous organs and also to describe fibres which are histologically similar but which are present in developing connective tissue. Recently, however, a number of workers[1-3] have shown that the basement membrane type of reticulin is a complex composed of collagen, carbohydrate and lipid which are released only after acid hydrolysis. Windrum *et al.*[3] have questioned the assumption that the two types of reticulin are identical. We now report evidence which suggests that they are indeed different structures.

In the early stages of development of a granuloma produced by subcutaneous injection of carrageenin[4], the fibres present are largely of the reticulin type. Such tissue has been subjected to a differential extraction procedure[4] and examined histologically after each extraction. The histological examination showed that: (*a*) after extraction with $0 \cdot 2$ *M* sodium

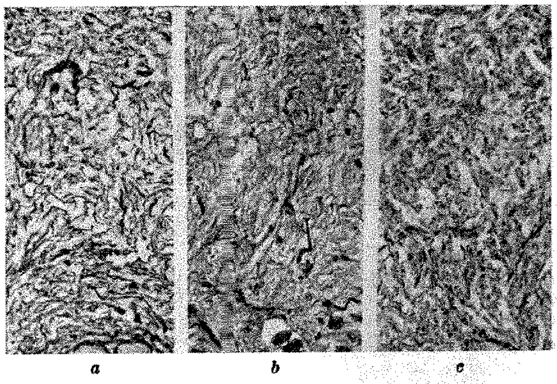

Fig. 1. Carrageenin granuloma after six days.
a, Normal control showing abundant silver staining reticulin fibres; *b*, after neutral salt extraction the fibres lose their argyrophilia and stain red with Van Gieson; *c*, extraction with citrate buffer after neutral salt gives almost complete removal of fibres.
All stained under identical conditions by silver impregnation/Van Gieson. (× *c.* 120)

chloride, pH 7·4, the fibres failed to stain with silver but took up the Van Gieson stain for normal collagen fibres; (*b*) following this with extraction with citrate buffer pH 3·6 removed the fibres almost completely (Fig. 1). The process extracts citrate-soluble collagen from the tissue[4], and this has been shown to contain little or no carbohydrate[5] and no lipid (unpublished data). Hence this type of reticulin is different from the reticulin of the parenchymatous organs. Extraction with 0·2 *M* sodium chloride removes neutral salt-soluble collagen[6], and it may be that the silver staining is due to the presence of a layer of this collagen type which is not yet incorporated firmly into the collagen fibre structure, although it has been shown recently that coating mature collagen fibres with a number of substances induces them to stain with silver[7].

This investigation will be reported in detail elsewhere.

An Isotope-Derivative Method for the Detection and Estimation of Œstrogens

About ten years ago Keston and co-workers developed an isotope dilution method for the estimation of amino-acids[1]. This method, by which the amino-group of amino-acids is labelled with radioactive 'pipsyl chloride' (*p*-iodophenylsulphonyl chloride, labelled with iodine-131), was not found applicable for other types of compounds until recently. Last year, however, this method was also used for the detection and estimation of histamine[2], pyrimidines[3] and 17-hydroxycorticosterone[4]. In the last method the labelling agent was 'pipsan' (*p*-iodophenylsulphonylic acid anhydride).

In this laboratory we are interested in the detection and estimation of œstrogens in the blood of dairy cattle and other animals. Not being satisfied with the usual fluorimetric and colorimetric methods, we adapted the pipsyl chloride method to our investigation.

From our experiments it appears that the phenolic group in ring *A* reacts easily with pipsyl chloride in a 0·75 per cent solution of borax in 75 per cent acetone. The reaction is almost complete in 15 min. at room temperature if about 10 μgm. of œstrogen are esterified with 2 mgm. of pipsyl chloride in 0·4 ml. of 75 per cent acetone solution. Whether the hydroxyl groups at C_{17} (œstradiol and œstriol) and C_{16} (œstriol) are partially esterified under the given conditions has not yet been elucidated. The excess of reagent can be hydrolysed by adding a 2 per cent aqueous borax solution and heating at 50° C. for 30 min. Partition between benzene and water leaves the hydrolysed reagent in the aqueous phase, whereas the pipsyl derivatives and some both hydrolysed and non-hydrolysed pipsyl chloride are left in the benzene layer. Pipsyl chloride and the pipsyl derivatives of œstrone, œstradiol-17β and œstriol can be separated from each other by a paper chromatographic method, using Schleicher and Schüll 2043^a paper, previously dipped in a 10 per cent solution of paraffin oil in ether. An ascending technique is applied with mixtures of carbon tetrachloride/paraffin oil (7 : 2) and cyclohexane/paraffin oil (3 : 1) as the mobile phases. Complete separation is achieved after a 15 hours run (Fig. 1). The latter solvent has the disadvantage that the œstriol derivative remains on the start.

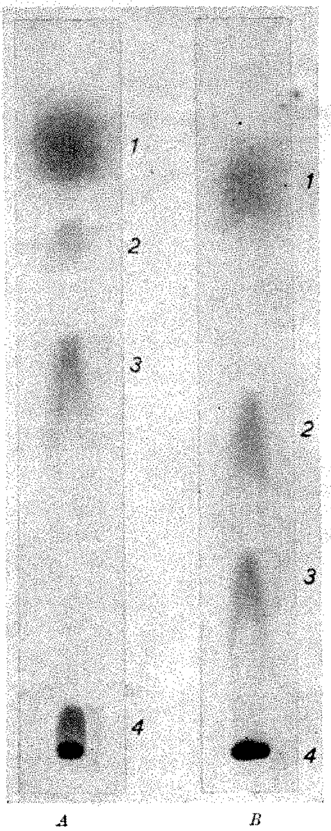

Fig. 1. Autoradiographs of the paper chromatographic separation of pipsyl chloride (1) and the pipsyl derivatives of œstrone (2), œstradiol-17β (3) and œstriol (4). Solvents: *A*, carbon tetrachloride–paraffin oil 7 : 2; *B*, cyclohexane–paraffin oil 3 : 1

So far amounts up to 0·3 μgm. œstrogen could be detected. We are continuing our experiments with more active preparations of pipsyl chloride to increase the sensitivity of the method.

In preliminary experiments blood samples of both non-pregnant and pregnant cows were examined. Extracts were prepared according to the usual methods for œstrogen determination. Each time one litre of blood was worked up. In the extracts a number of compounds which react with pipsyl chloride was detected. Whether one or more of these compounds are identical with one of the three common œstrogens is under investigation. A method for the quantitative determination of œstrogens by means of the isotope indicator method, which makes use of an indicator labelled with pipsyl chloride-^{35}S[5], is also under development.

Results and details of the method will be published elsewhere.

This work is financed by the Agricultural Research Council T.N.O. Thanks are due to Prof. L. Seekles for laboratory facilities and for his interest in the investigation, to Mr. G. H. Frederik and Mr. J. A. M. Clemens for making the autoradiographs and to Miss F. A. Schippers for technical assistance.

Studies on the Biosynthesis of Neuraminic Acid

IN recent years neuraminic acid[1] and several of its derivatives, such as sialic acid and lactaminic acid, have been shown to be constituents of mucoproteins, gangliosides and related naturally occurring substances. Although the chemical structure of neuraminic acid has not been established as yet, its elementary composition and some of its chemical properties are known. The existence of this substance as either the free carboxylic acid or its corresponding lactone form has been demonstrated[2], and it has been postulated that a hexosamine residue is present[3]. The biological function of neuraminic acid remains obscure, although recent evidence indicates that this compound is liberated from its parent polysaccharide by the action of influenza virus or virus-receptor-destroying enzymes[3,4].

Since the biosynthetic origin of neuraminic acid has not been studied, an investigation was carried out with four objectives in mind: (1) to investigate the biosynthetic relationship between neuraminic acid and glucose and its metabolic precursors; (2) to establish on biosynthetic grounds whether a hexosamine residue is actually present in neuraminic acid; (3) to throw light, if possible, on the origin of the carbon atoms not associated with the postulated hexosamine residue; and (4) to provide carbon-14-labelled neuraminic acid which could be used to establish its chemical structure.

In the experiments to be reported here, uniformly labelled D-glucose-^{14}C with a specific activity of $4 \cdot 53 \times 10^6$ counts/min. per mgm. of carbon was injected intraperitoneally into rats in two experiments. The total carbon-14 activity injected into each rat was 14,887,000 counts/min. (8·2 mgm. of glucose-^{14}C). In the first experiment, two rats, each weighing 250 gm. and fasted for 8 hr., were injected with glucose-^{14}C in three equal doses at 2-hr. intervals. Twelve hours after the last injection the animals were killed, skinned and their combined tissues converted to a dry powder after homogenizing with acetone in a Waring blendor. The second experiment was conducted similarly but with only one rat weighing 450 gm. and fasted for 25 hr. before being given glucose-^{14}C. The carbon-14 activity of samples plated out on planchets as infinitely thin layers was measured in a gas-flow counter. Neuraminic acid, glucosamine and galactosamine were isolated from the acetone powders.

A newly devised procedure, the details of which will be published elsewhere, was used for isolating neuraminic acid. In brief, this isolation procedure involves the following steps: (1) The powdered carcass was refluxed with 5 per cent hydrochloric acid-methanol (w/v) for 5 hr. (2) After removal of the excess hydrochloric acid from the supernatant, 0·2 *N* aqueous mercuric chloride was added and the resultant precipitate discarded. The filtrate was then neutralized with 'Amberlite *IR 4B*' (OH form). (3) The filtrate and aqueous washings obtained from this resin were combined and placed on a column (2·5 cm. × 70 cm.) of 'Dowex-50', 4 per cent cross-linked, 200–400 mesh. In the upper third portion of this column, 'Dowex-50' was present in the mercuric form, whereas the lower two-thirds of the column contained the cation exchanger in its hydrogen form. The column was washed with water until the effluent solution did not show a green colour upon addition of Bial's reagent. (4) The column was now eluted with 0·3 *N* hydrochloric acid, whereupon hexosamine and the neuraminic acid were obtained in two discrete fractions. The hexosamine fraction was eluted first, and from it glucosamine and galactosamine were isolated according to the method of Gardell[5]. (5) The effluent fraction containing neuraminic acid was concentrated to a small volume after removal of hydrochloric acid. The concentrate was placed on 'Dowex-50' (H form) in a column (2·5 cm. × 40 cm.) and neuraminic acid was eluted with 0·3 *N* hydrochloric acid with a yield of approximately 12 mgm. per 100 gm. wet tissue. Neuraminic acid was crystallized after removal of hydrochloric acid from a mixture of methanol, water and petroleum ether (boiling point 30°–60°) and recrystallized first from methanol-water and then from water.

Neuraminic acid intended for use as carrier substance was isolated by the same procedure from bovine submaxillary mucopolysaccharide. The elementary analysis of this material (C, 42·49; H, 7·02; N, 4·55 per cent) was in good agreement with that reported by Klenk and Lauenstein[1]. The chemical identity and homogeneity of the unlabelled carrier substance and the radioactive material isolated was established as follows: (1) The absorption coefficient of the coloured material resulting from Bial's reaction was compared with that of an authentic sample of neuraminic acid; we are indebted to Prof. E. Klenk for supplying us with a sample of methoxy neuraminic acid for comparison with our material. (2) Paper chromatography was carried out in one of the two systems: (*a*) *sec*-butanol/acetic acid/water (4 : 1 : 5), and (*b*) *n*-butanol/acetic acid/water (4 : 1 : 1). (3) Infra-red spectra were used for comparison with an authentic sample. (4) Radiochemical purity after repeated recrystallizations served as an index of purity in the case of the carbon-14-labelled material.

In all instances, neuraminic acid was isolated as its methoxy derivative. Glucosamine and galactosamine were isolated as the hydrochlorides. The carbon-14 activity of the isolated compounds is

Table 1. CARBON-14 ACTIVITY OF NEURAMINIC ACID, GLUCOSAMINE AND GALACTOSAMINE

	Activity (counts/min./mgm. carbon)	
	Experiment 1	Experiment 2
Neuraminic acid	1,170	980
Glucosamine	1,560	
Galactosamine	2,580	

expressed as counts/min. per mgm. of carbon (Table 1). In the case of neuraminic acid, the carbon-14 activity has been corrected to eliminate the isotope dilution due to the methoxy carbon atom. In the case of the hexosamines, the carbon-14 activity represents that of the free hexosamine.

The results appear to support the thesis that the carbon atoms of glucose contribute directly to the biosynthesis of neuraminic acid, but do not warrant any conclusions as to the mechanism of biosynthesis. Since the injected glucose-^{14}C was diluted by the rat's glucose pool, which has been reported to be 130 mgm. per 100 gm. of rat tissue[6], it can be estimated that the isotope concentration in neuraminic acid has undergone a dilution of less than one hundred-fold. The extent of this dilution is interpreted as being indicative of a direct contribution of glucose carbon atoms to the biosynthesis of neuraminic acid.

A comparison of the specific carbon-14 activity of neuraminic acid with that of glucosamine and galactosamine shows that the isotope concentration of glucosamine approaches that of neuraminic acid but is less than that of galactosamine by a factor of 1·7. Although the pool-sizes of some of the intermediates as well as the rates of turnover are unknown at present, it seems reasonable to postulate that glucosamine is not a likely precursor of neuraminic acid, but that galactosamine could conceivably function in such a capacity.

This work was supported, in part, by a grant from the United States Atomic Energy Commission.

Separation of Steroid Conjugates by Paper Electrophoresis

THE application of the principle of electrophoretic separation on paper to steroids is limited by their relatively low polarity, so that they do not readily migrate under the influence of an electric current, and also by their sparing solubility in aqueous media. By converting the steroids into derivatives with polar groupings, some separation has been achieved (Voigt and Beckmann[1], 1953, using the hemisuccinates; McKinley[2], 1955, using the mono- and di-phenylhydrazone derivatives). Our early experiments, begun before the publication of these authors' results, were along similar lines, and with somewhat similar results. It did not seem likely, however, that electrophoretic separation would be so convenient a method as chromatography, which has been adapted by Lembart and Schneider[3] for the separation on paper of mixtures of pure steroid conjugates. The natural occurrence of more polar steroid derivatives, the sulphates and glucuronides in urine, suggested to us that these might undergo electrophoretic separation on paper. Although the individual steroids could not be resolved, the two groups of conjugates were sharply separated.

The apparatus used was a simple box type, accommodating the paper strips horizontally. Of several systems tried, a veronal buffer solution of ionic strength 0·1 and *p*H 8·6 containing 20 per cent ethanol was found to give the best results. Whatman No. 31 filter paper was used, and a potential difference of 240 volts and a current strength of 0·5 m.amp. per cm. of paper was applied for 16 hr. A mixture of dehydroisoandrosterone and its sulphate subjected to electrophoresis under these conditions showed that the steroid sulphate travelled 11 cm. towards the anode while the free steroid had moved slightly towards the cathode. An extract containing both the free and conjugated steroids was obtained from urine by half saturation with ammonium sulphate followed by extraction with an ether–alcohol mixture. An amount of extract containing approximately 200 micrograms of total steroid was used for separation. After drying, the paper strip was treated with Zimmermann reagent. Two violet bands were obtained, both on the anode side of the point of application, the glucuronide fraction varying from 5 to 7 cm., and the sulphate from 8 to 10 cm. from the initial line. In addition, a very small amount of free steroid was found at, and slightly to the cathode side of, the starting point. A number of bands due to other non-steroid urinary constituents were also present; for example, a brown band of urea was always seen at about 1 cm. on the cathode side.

In addition to experiments on mixtures of known steroids, further evidence suggesting the composition of the two fractions was given by showing that the glucuronide fraction was almost completely removed by previous treatment of the urine with glucuronidase before extraction, and by demonstrating the virtual absence of glucuronic acid in the sulphate fraction. The fractions can also be quantitatively estimated after elution from an unstained strip, and this has been carried out both for normal and pathological urines and for blood. Table 1 shows the results from a normal adult urine, as an example.

Table 1

	Amount applied	Free steroids	Sulphates	Glucuronides
17-ketosteroids	140 μgm.	3 μgm.	37 gm.	99 μgm.
17-OH corticosteroids	88 μgm.	2 μgm.	6 gm.	82 μgm.

Besides affording a simple means of estimating the proportions of steroid sulphates and glucuronides in urine and blood, for which, so far as we know, there is no direct method, the procedure can also be applied for purifying the fractions prior to hydrolysis and subsequent identification of the components, and also for preparative purposes. Work along these lines is actively proceeding, and fuller details of the method and its applications will be published elsewhere.

Effect of Di*iso*propylphosphorofluoridate on the Acetylcholine Content of Flies

Previous studies[1,2] of the action of di*iso*propylphosphorofluoridate (DFP) on insects have been primarily concerned with the inhibition of cholinesterase, but nothing has been reported about its effect on the acetylcholine (ACh) content. We have therefore examined the effect of di*iso*propylphosphorofluoridate on acetylcholine-levels in the blowfly (*Calliphora erythrocephala*) and the housefly (*Musca domestica*).

Flies were immobilized by cooling at 0° C.; 10 μgm. di*iso*propylphosphorofluoridate in 1 μl. acetone was applied to the dorsal surface of the abdomen, and, when paralysed (about 3 min.), the flies were transferred in groups to open dishes. At intervals after treatment with di*iso*propylphosphorofluoridate a group was taken for acetylcholine determination, either on the whole flies, or on the heads, thoraces or abdomina. Acetylcholine was extracted by the method of Lewis and Smallman[3], and assayed on the eserinized rectus abdominis muscle of the frog. Corresponding estimations were made on control flies treated with 1 μl. acetone only. The results are shown in Fig. 1.

In the whole fly there is a slow increase in acetylcholine content after di*iso*propylphosphorofluoridate treatment; but the distribution of acetylcholine within the insect is markedly influenced. In the head the level of acetylcholine begins to fall after about ½ hr., and at 3½ hr. it is only about 25 per cent of the control value. In the thorax there is an increase in acetylcholine content; but most striking is the accumulation of acetylcholine in the abdomen, where the level rises from less than 0·0005 μgm./abdomen in the control to about 0·07 μgm./abdomen in the poisoned fly after 3½ hr.

In comparable experiments with the housefly we have shown a similar fall in the acetylcholine content of the head of the insect poisoned with di*iso*propylphosphorofluoridate. Winteringham and Harrison[4], working with houseflies injected with 2-^{14}C-acetate, reported that of the total soluble carbon-14 in the head the proportion present as acetylcholine was doubled ½ hr. after treatment with di*iso*propylphosphorofluoridate, but after 5 hr. had fallen to the control level; and it may therefore appear that our results are in contradiction to their findings. However, these workers have also shown[5] that the total soluble carbon-14 in the head (mainly in amino-acids) is decreased ½ hr. after treatment with di*iso*propylphosphorofluoridate, so that the increase in the proportion of carbon-14 present as acetylcholine does not represent a corresponding increase in the absolute amount of acetylcholine.

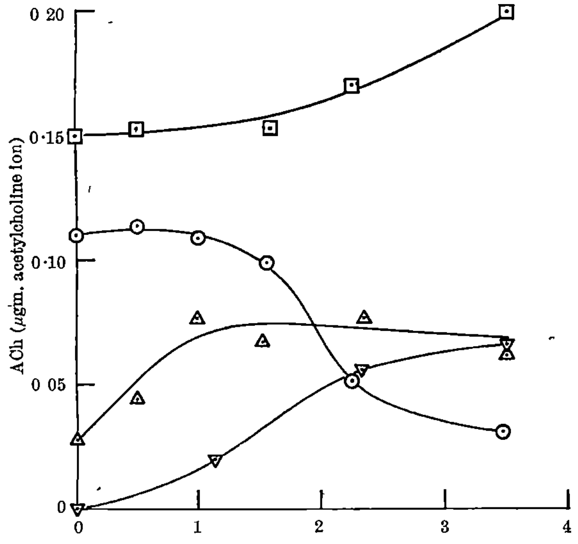

Fig. 1. Change in acetylcholine-levels in the blowfly after treatment with di*iso*propylphosphorofluoridate. (Levels in the untreated fly are plotted at zero time.) ⊡—⊡, Whole fly; ⊙—⊙, head; △—△, thorax; ▽—▽, abdomen

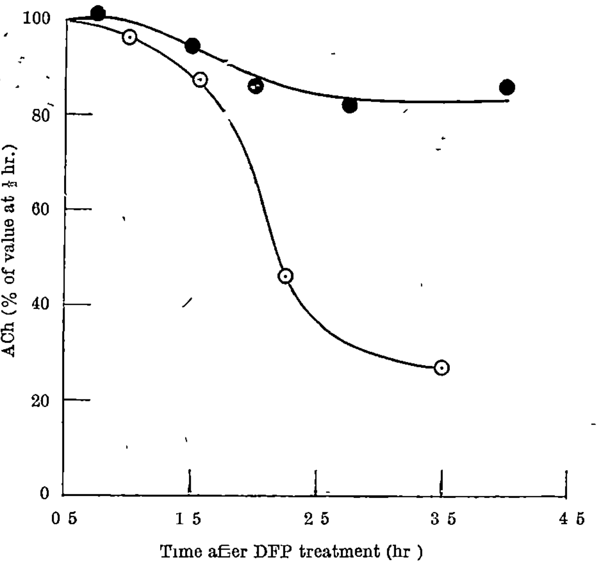

Fig. 2. Effect of decapitation on the fall in acetylcholine-level in the head of the blowfly treated with di*iso*propylphosphorofluoridate. ○—○, Head of intact fly, ●—●, head isolated ½ hr. after treatment with di*iso*propylphosphorofluoridate

We have also measured the acetylcholine content of the head of the poisoned blowfly at intervals after decapitation. Flies were decapitated ½ hr. after treatment with di*iso*propylphosphorofluoridate in groups of fifteen. Heads from one group were extracted immediately after decapitation and those from the remaining groups at intervals up to 3½ hr. The change in acetylcholine content in these heads after decapitation is shown in Fig. 2 in comparison with that occurring in the head of the intact poisoned fly over a similar period (both sets of values expressed as percentages of the acetylcholine content ½ hr. after treatment with di*iso*propylphosphorofluoridate). It is clear that the fall in the level of acetylcholine in the head of the fly treated with di*iso*propylphosphorofluoridate is largely prevented when the head is isolated from the rest of the body.

Similar experiments with abdomina cut from flies ¾ hr. after treatment with di*iso*propylphosphorofluoridate showed that the acetylcholine-level in the isolated abdomen remained constant, whereas that in the abdomen of the intact poisoned fly continued to increase.

These results suggest that the changes in the amount of acetylcholine in the head and abdomen of the fly treated with di*iso*propylphosphorofluoridate are due mainly to redistribution of acetylcholine within the insect and not to destruction or synthesis *in situ*. Although it might be expected that such a redistribution would occur via the hæmolymph, no significant amount of acetylcholine could be detected in hæmolymph from flies treated with di*iso*propylphosphorofluoridate. However, much of the acetylcholine in the abdomen was found in the contents of the hind-gut. Thus it may be that, in flies treated with di*iso*propylphosphorofluoridate, acetylcholine is in fact redistributed via the hæmolymph, but is removed from it and reconcentrated in the hind-gut, possibly by the action of the Malpighian tubules.

Fuller details of these and of other experiments on flies treated with di*iso*propylphosphorofluoridate will be reported elsewhere.

Determination of Fat in Mutton Carcasses by Measurement of Specific Gravity

In albino rats[1], guinea pigs[2], swine[3] and cattle[4] a close relationship has been shown to exist between specific gravity and percentage fat in the eviscerated carcass. Likewise in living man[5] a relationship has been established between specific gravity and percentage fat in the body.

In the present work the relationship between specific gravity of the whole carcass and the percentage fat content of the half carcass and of certain joints has been determined on three groups of five six-year-old Romney pasture-fed ewes reared under typical New Zealand flat-country conditions. The first group of ewes was killed at the outset of the experiment. The second and third groups were killed twenty-eight days later. Animals in the second group were pasture-fed for 1 hr. and starved for 23 hr. per day for the duration of the experiment, while the animals in the third group were grazed on pasture throughout.

After chilling for approximately 18 hr. after slaughter, the specific gravity of the kidney-free carcasses was determined by weighing in air and then in water at a water temperature of 17°–20° C. The surface temperature of carcasses was 11°–12° C.

Following the determination of whole carcass specific gravity the carcasses were stored for a period in a freezing chamber. The frozen carcasses weighing 55·2–78·2 lb. were then divided down the middle of the back with a meat band saw and the right side sliced into pieces one-eighth to one-quarter of an inch in thickness, again using the band saw. These slices, consisting of bone, muscle, fat and other tissues, were then readily minced.

Obtaining a uniform mince of all the soft and hard tissues of the carcass has hitherto presented great difficulty. This has been effectively overcome by the technique just described which, so far as we are aware, has not previously been recorded in the literature. Slight modifications of this technique are also being investigated in this Department in studies of functional anatomy, parturition and whole-animal chemical determinations of meat animals.

The fat content in six samples per animal was determined by using a slight modification of the method of Barnicoat and Shorland[6]. The standard error of the mean of these six samples was ± 0·39 and the coefficient of variation was 2·5 per cent. Percentage fat from the 15 half-carcasses varied from 26·1 to 45·4, and specific gravity of the whole carcasses varied from 1·009 to 1·049.

The left side of each carcass was divided into leg and loin, described by Pálsson[7], as well as a ninth–tenth–eleventh rib cut. The bone, muscle and fat contents were determined by dissection following the method of Pálsson[7].

The linear regression equations of the dependent variables Y, Z, U and W on the independent variable specific gravity together with their standard errors of estimate and their correlation coefficients are as follows:

Where X is $\frac{1}{\text{specific gravity}}$; Y is per cent ether extract fat in half-carcass; Z is per cent dissectable fat of leg plus loin; U is per cent ether extract fat in 9–10–11 rib cut; W is per cent dissectable fat in 9–10–11 rib cut; then

$$Y = 100\left(\frac{5\cdot680}{\text{specific gravity}} - 5\cdot138\right);$$

$$S_{xy} = 3\cdot196 \text{ per cent}; \qquad r_{xy} = 0\cdot877;$$

$$Z = 100\left(\frac{4\cdot965}{\text{specific gravity}} - 4\cdot512\right);$$

$$S_{xz} = 3\cdot131 \text{ per cent}; \qquad r_{xz} = 0\cdot852;$$

$$U = 100\left(\frac{7\cdot386}{\text{specific gravity}} - 6\cdot695\right);$$

$$S_{x.u} = 4\cdot706 \text{ per cent}; \qquad r_{xu} = 0\cdot877;$$

$$W = 100\left(\frac{6\cdot479}{\text{specific gravity}} - 5\cdot810\right);$$

$$S_{x.w} = 4\cdot764 \text{ per cent}; \qquad r_{xw} = 0\cdot814.$$

These results show that the relationship between specific gravity of the whole carcass and the percentage fat content of the half-carcass and joints is high. Thus the specific gravity method of estimating percentage fat content reported for other species can be applied in the sheep.

A detailed report of this investigation will appear elsewhere.

Synthesis of Levan by Pseudomonads

THE property of forming levan from sucrose is rather common among *Bacillus* species[1] and is also found in *Streptococcus salivarius*[2] and *Aerobacter levanicum*[3,4]. Further, levan is produced by many phytopathogenic *Pseudomonas* and *Xanthomonas* species[5,6], and is said to be formed by *Pseudomonas betae-gelatae*[7], isolated from thawing sugar-beets. However, no mention has been made of levan-producing *Pseudomonas* species isolated from other than diseased or killed plant material.

In the course of an investigation on levan-synthesizing bacteria, colloidal solutions of levan in distilled water were regularly stored in the icebox at 2° C. Some of these solutions were found to have become infected by organisms, apparently capable of using levan as sole source of carbon. After isolation, however, the predominating organism proved also to be able to produce a polysaccharide on 4 per cent sucrose with 1½ per cent peptone agar. After cultivation at 25° C. for 2–3 days in liquid 4 per cent sucrose 1½ per cent peptone medium, the polysaccharide formed was precipitated by adding three parts of ethyl alcohol and identified as a levan according to the methods of Hestrin *et al.*[3]. Further examination showed the organism to be *Pseudomonas fluorescens*.

Since here a levan-synthesizing pseudomonad was found which did not originate from plant material, it seemed worth while to examine the possibility of a dependable enrichment culture for this organism. Sterile 1 per cent solutions in distilled water of levans of different origin were inoculated with garden soil, ditch water or tap water. After incubation for 2 days at 25° C. under aerobic conditions and subculturing once more in the same liquid medium, transfers were made on 4 per cent sucrose with 1½ per cent peptone agar. Several strains of the predominating, slime-producing organism were readily isolated, all of which have been proved to be levan-forming *Pseudomonas fluorescens* strains. Apparently, small amounts of impurities in the levan preparations and inoculation materials fulfil the mineral requirements of this organism. These simple growth conditions in the enrichment medium were found to be essential for its selectivity, since the mere addition of mineral salts caused a great variety of other organisms to come to the fore.

Furthermore, it has been found in this laboratory that *Pseudomonas aureofaciens* is a levan-forming bacterium, as already mentioned recently by Kluyver[8]. All strains examined possessed this property; they were isolated from mixtures of clay and kerosene (2 strains) and soil (1 strain).

On screening a number of *Pseudomonas* strains from the bacterial collection of our laboratory, four more strains, belonging to the species *Pseudomonas fluorescens* (3 of 8 strains) and *Pseudomonas chlororaphis* (1 strain), were found to be able to synthesize this polysaccharide. None originated from plant material.

No levan synthesis was found in about 80 strains of different *Pseudomonas* species, among which were: *Ps. putida, Ps. aeruginosa, Ps. fluorescens, Ps. aromatica* var. *quercito-pyrogallica, Ps. calco-acetica* and *Ps. punctata.*

Thus, in a total of three *Pseudomonas* species, levan-forming strains have been found, which did not originate from diseased or killed plant material. All these strains produce levan in considerable quantities; maximal production was shown by a strain of *Pseudomonas aureofaciens* which in one case produced 83 per cent of the theoretical yield on cultivation at 25° C. in 4 per cent sucrose with 1½ per cent peptone medium on a rotary shaker.

The greater part of the levan-synthesizing strains which have been identified as *Pseudomonas fluorescens* is able to use oxygen as well as nitrate as hydrogen acceptor. These nitrate-reducing strains appeared able to synthesize levan also in nitrate-containing sucrose media in total absence of air. Here, maximal production of levan was 49 per cent.

All the levan-producing *Pseudomonas* strains proved to have constitutive, endocellular levan-sucrases (= saccharose → levan-transfructosidase[9]); moreover, all these strains could be characterized on sucrose-containing agar media by colonies having a typical radial structure. In these respects, apparently all Gram-negative, levan-producing bacteria resemble each other closely since *Aerobacter levanicum* was found to show the same characteristics.

Occurrence of a Malic Enzyme free of Oxalacetic Decarboxylase in Silkworm Hæmolymph

HÆMOLYMPH of the larval silkworm (*Bombyx mori* L.) contains a triphosphopyridine nucleotide-linked 'malic' enzyme that has been purified by ammonium sulphate fractionation followed by adsorption and elution from calcium phosphate gel[1,2]. It was of interest to measure the oxalacetic decarboxylase activity of the 'malic' enzyme from silkworm, since those of pigeon liver[3,4] and wheat germ[5,6] exhibit a constant ratio (approximately 1·2 : 1) between oxalacetic decarboxylase and 'malic' enzyme activities throughout all stages of their purification. Recently, a diphosphopyridine nucleotide-linked 'malic' enzyme free of oxalacetic decarboxylase was purified from homogenates of *Ascaris lumbricoides*[7]. 'Malic' enzyme activity has been reported in crude homogenates of larvæ from the blowfly[8]. These extracts also decarboxylate oxalacetate; but it has not yet been established whether both reactions are catalysed by the same enzyme.

The test system used for the spectrophotometric assay of the 'malic' enzyme of silkworm blood contained the following components (in µmoles/2·2 ml.): *tris* (hydroxymethyl) aminomethane buffer *p*H 8·5, 40; magnesium sulphate, 10; *l*-malate, 10; triphosphopyridine nucleotide, 0·5; and enzyme. The assay was carried out in quartz cells ($d = 1\cdot0$ cm.) at 21° C. in a Beckman *DU* spectrophotometer. The control cell contained all the components except triphosphopyridine nucleotide. The activity of the 'malic' enzyme was calculated from the change in optical density at 340 mμ during the third minute of incubation; the unit being defined as that quantity which causes an increase in optical density of 0·01 unit/min.[9].

The manometric assay of oxalacetic decarboxylase was performed in the Warburg apparatus using flasks of approximately 5 ml. capacity; the test mixture contained the following (in μmoles/1·25 ml.): sodium acetate buffer, *p*H 4·5, 20; manganese chloride, 2·5; oxalacetate, 20; and enzyme. The oxalacetate, which had been brought to *p*H 4·5, was placed in the side arm and tipped after an equilibration period of 10 min. The gas phase was air and the incubations were carried out at 25° C. The control vessel contained enzyme inactivated by heating in a boiling-water bath for 3 min. and the gas evolved in this vessel was approximately the same as that produced in a vessel containing the complete incubation mixture without enzyme; thus, denatured silkworm-blood enzyme did not stimulate the non-enzymatic decarboxylation of oxalacetate. The unit of oxalacetic decarboxylase is that quantity of enzyme that causes an increase over the blank of 1 μl. carbon dioxide in 10 min. at 25° C.[9]. The blank value, due to the spontaneous decomposition of oxalacetate, was approximately 32 μl./10 min. One unit of oxalacetic decarboxylase was equivalent to 0·78 unit 'malic' enzyme under the stated experimental conditions.

The enzyme preparations used here were obtained by treating whole or dialysed silkworm blood from fifth-instar larvæ with ammonium sulphate and collecting the fraction separating between 40 and 50 per cent saturation. The precipitate from 15 ml. whole blood or 30 ml. dialysed blood was dissolved in 5 ml. water and suitable aliquots were used for the assay of the 'malic' enzyme and oxalacetic decarboxylase.

The results given in Table 1 illustrate that preparations possessing 57–100 units of 'malic' enzyme activity do not show equivalent oxalacetic decarboxylase activity and, like the *Ascaris lumbricoides* enzyme[7], do not catalyse the decarboxylation of oxalacetate. The data in Table 1 also show that no activation of oxalacetic decarboxylase by triphosphopyridine nucleotide occurred with a preparation of the silkworm blood 'malic' enzyme, although it has been reported that small quantities of triphosphopyridine nucleotide stimulate the oxalacetic decarboxylase activity of the pigeon liver 'malic' enzyme[10] and inhibit that of the wheat germ[5].

Table 1. OXALACETIC DECARBOXYLASE AND 'MALIC' ENZYME ACTIVITY OF SILKWORM BLOOD PREPARATIONS

Preparation*	'Malic' enzyme (units)	Oxalacetic decarboxylase			
		Assay period (min.)	Units		
			No TPN	TPN 0·05 μmole	TPN 0·1 μmole
DB–25	57	4–10	3·0		
		10–15	0·0		
DB–26	83	2·5–5·0	0·0		
		6–10	1·0		
		10–15	1·0		
P–2	100	0–9	2·0	−3·0	−3·0
		10–15	2·0	−2·0	0·0
		15–20	2·0	0·0	−2·0

* The preparations were obtained, as described in text, by ammonium sulphate fractionation of dialysed (*DB*-series) or whole (*P*-series) silkworm blood.

It is concluded that oxalacetic decarboxylase is not associated with the 'malic' enzyme of silkworm blood.

Ortho-Tyrosine in an Insect Cuticle

AN examination of a developing insect cuticle by means of paper partition chromatography has shown that the changes taking place in amino-acid composition primarily concern the aromatic members. Larval cuticles of *Calliphora vomitoria* have been hydrolysed at different stages of development in 6 *N* hydrochloric acid and chromatograms developed using butanol/acetic acid/water and phenol saturated with water as solvents. The positions of the amino-acid spots were located by spraying with ninhydrin. At all stages the following amino-acids were recognized: alanine, arginine, glutamic acid, glycine, leucine, lysine, proline, serine, threonine, and valine. In addition, tryptophan is present before the onset of puparium formation. The chief differences between the various developmental stages concern the presence or absence of phenylalanine and *para*-tyrosine. At the concentration of hydrolysate used, phenylalanine is only very faintly distinguishable in the cuticles of four- and five-day old larvæ; but in the seven-day old and white puparial cuticles it is abundant. Thereafter, however, in the one-day old and fully hardened puparia, it is absent. Somewhat similarly, *para*-tyrosine is present at all stages up to, and including, the white puparium, but is absent from the hardened puparial cuticle.

In addition, however, to phenylalanine and *para*-tyrosine, the cuticle of the seven-day larva yields a spot, not found in any of the other stages, which is indistinguishable from that given by an authentic sample of *ortho*-tyrosine. This appears to be the first indication of the presence of *ortho*-tyrosine in an insect cuticle, and in view of the roles which have been attributed to tyrosine in the development of the cuticle[1], this distinction between *ortho*- and *para*-tyrosine is clearly important. It is possible that the disappearance from the chromatograms of ninhydrin-positive spots corresponding to phenylalanine and *para*-tyrosine may be an indication of the participation of the amino-groups of these acids in the tanning process. But *ortho*-tyrosine disappears not only before this process begins, but even before the white puparium stage is reached; and its appearance and disappearance at about seven days may well be correlated with the preparation of the cuticle for the later hardening process.

I am grateful to Dr. C. E. Dalgliesh for the gift of an authentic sample of *ortho*-tyrosine. This investigation into the amino-acid metabolism of a developing insect cuticle is being continued, and a full account will be given in due course.

Inhibition of Luminescence by Sodium Diethyldithiocarbamate and its Recovery by Sodium Borate in Luminous Bacteria

RECENTLY, significant roles of heavy metals which affect pigment formation in various animals have been examined in this laboratory[1,2].

I have investigated the effects of various metals and metal-chelating compounds on the luminescent reaction in a luminous strain, *Photobacterium phosphoreum*. The bacteria were cultured for 18 hr. in the nutrient medium at 25° C. Cells were harvested by centrifugation and suspended in 3 per cent sodium chloride solution. This suspension emitted a very brilliant light continuously for several hours, but if sodium diethyldithiocarbamate solution was added to this suspension (final concentration 10^{-3}–10^{-4} *M*), the luminescence ceased or decreased rapidly in a few seconds.

Among many kinds of metal-chelating compounds thus far tested, namely, sodium diethyldithiocarbamate, diphenylthiourea, ethylenediamine tetraacetate, 8-oxyquinoline, phenylthiourea, thiourea and thiouracil, the first was the most effective in stopping the bacterial luminescence. This inhibitory effect was eliminated by addition of certain metal solutions such as ferric chloride, cupric chloride, zinc chloride and sodium pyroborate.

Among the metal solutions thus far tested, sodium pyroborate solution was the most effective in the recovery of luminescence, and boric acid was as active as 60 per cent of sodium pyroborate in an equimolal concentration. Sodium diethyldithiocarbamate solution to which sodium pyroborate was added previously has little effect on the luminescent reaction.

Sodium diethyldithiocarbamate solution has two absorption maxima at 255 mμ and 280 mμ respectively ; but these peaks disappear when cupric chloride is added to the solution. On the other hand, sodium pyroborate shows no effect on the elimination of these peaks. Therefore, the concentration of sodium diethyldithiocarbamate may be estimated spectrophotometrically by examination of these absorption peaks in the case where sodium pyroborate is used.

Equal volumes of luminescent bacterial suspension were put into four tubes. Sodium diethyldithiocarbamate solution was added to the first and second tubes so that the final concentration was equal. After the luminescence of both tubes disappeared, sodium pyroborate solution was added to the first tube and the same volume of distilled water was added to the second tube as a control. The luminescence of the second tube was recovered as described before. Then the bacterial cells were removed from these four tubes by centrifugation.

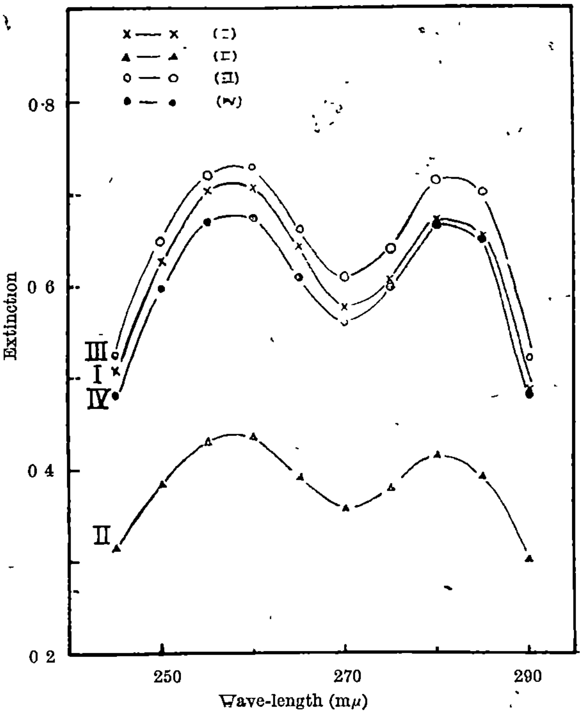

Fig. 1. Absorption spectrum of sodium diethyldithiocarbamate in the supernatant of the first tube (I), the second tube (II), the third tube (III) and the fourth tube (IV). The concentration of the carbamate and sodium pyroborate used is 10^{-4} *M*

After centrifugation, sodium diethyldithiocarbamate solution was added to the third and fourth tubes so that the final concentration was the same as before. Then sodium pyroborate solution was added to the third tube and the same volume of distilled water was added to the fourth tube.

These supernatants were assayed spectrophotometrically. The result (Fig. 1) shows that sodium diethyldithiocarbamate concentration in the supernatant layer of (II) is lower than that of (IV), but sodium diethyldithiocarbamate concentration in the supernatant layer of (I) is nearly equal to that of (III). This means that sodium diethyldithiocarbamate which is added to the bacterial suspension is absorbed by bacterial cells and removed with them by centrifugation, but it is liberated from the cells into the supernatant layer when sodium pyroborate is added.

The luminescent bacterial cell to which sodium pyroborate was previously added was not affected by the subsequent addition of sodium diethyldithiocarbamate ; but the effect of this compound was as active as the untreated cells when the cells were centrifuged and freed from sodium pyroborate prior to the addition of sodium diethyldithiocarbamate.

Judging from these results, it may be assumed that the recovery of luminescence by the sodium pyroborate is due to the removal of sodium diethyldithiocarbamate from the bacterial cells.

Interrelationships of Germination Inhibitors and Oxygen in the Dormancy of Seed of *Betula*

IT has been shown that for 'seeds' (achenes) of *Betula pubescens* a much higher percentage germination is obtained in long days than in short days (approximately 90 and 25 per cent respectively)[1]. The effect of light is presumably on the living tissue of the embryo; but it has been found that excised embryos germinate even in complete darkness.

The alteration of the response of light-sensitive seeds to light by the removal of the seed coat is already well known; but we are still far from understanding the cause of this. It has been demonstrated that in some seeds, germination inhibitors are located in the seed coat, and it has been suggested that the embryo is allowed to germinate because of the removal of the inhibitor.

Investigations on this problem have been carried out on birch seeds. It has been possible to obtain a water-soluble inhibitor from these seeds which strongly inhibits the germination of birch embryos and lettuce seed. In later experiments extracts were made using 100 per cent methanol as solvent, thus avoiding the extraction of proteinaceous material. The extract was chromatographed on Whatman No. 1 paper using a solvent composed of 99 parts 70 per cent aqueous *iso*propanol to 1 part ammonia (specific gravity, 0·880). Using excised birch embryos (in the dark) (Fig. 1) and lettuce seed (var. Newmarket) for bio-assay, a non-fluorescent inhibitor has been located running between R_F 0·7 and 0·9. It was possible to extract seeds both with and without embryos, and the same inhibitor was found in both these samples, thus indicating that it must be present in the pericarp. When the embryos are planted on filter paper soaked in the inhibitor, no germination occurs in the dark, but the inhibition is overcome when the embryos are exposed to light.

The question arises as to whether this inhibitor is of functional significance in controlling the dormancy of the seed. Experiments carried out on seeds from which some, but probably not all, of the inhibitor has been leached, show that the photoperiodic response is altered by this treatment, giving a high percentage germination even in short days (70 per cent). It is not possible, however, to obtain any germination of leached seeds in the dark.

It is known that in some seeds the enclosing structures restrict the inward diffusion of oxygen[2]. One of the effects of seed-coat removal in birch, therefore, apart from the removal of the inhibitor, might be to make more oxygen available to the embryo. By slitting the pericarp and endosperm it is possible to allow of the entry of oxygen but at the same time maintain the inhibitor around the embryo. After this treatment, approximately 50 per cent of the seeds germinate in the dark, whereas intact seeds do not germinate at all. It is clear, therefore, that the behaviour of the seeds is profoundly modified by slitting the seed coat even though the inhibitor is still present. Furthermore, it was later found that approximately 20 per cent germination could be brought about in the dark simply by making one scratch, the length of the seed, in the pericarp. The results of a number of experiments suggest that these effects are due to enhanced oxygen entry, since it is possible to secure 100 per cent germination of both slit and scratched seeds in the dark if the oxygen concentration is increased to 50 per cent. Moreover, the photoperiodic response can be altered by increasing the oxygen concentration. In an atmosphere of 50 per cent oxygen, 70 per cent germination occurs in short days compared with 15 per cent for the control in air.

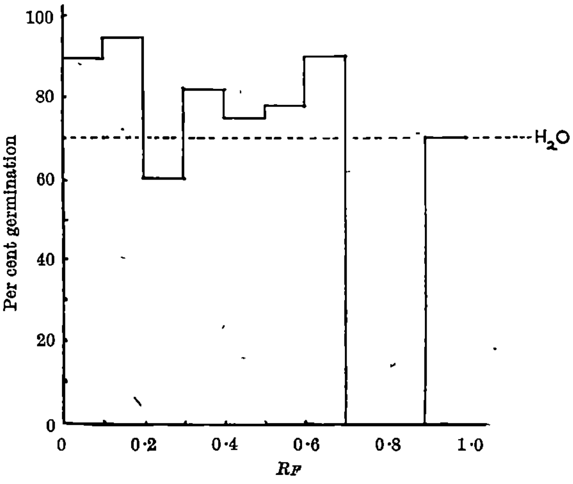

Fig. 1. Bio-assay of the chromatogram of a methanol extract of birch seed

There appear, therefore, to be two results of removing the seed coat. First, the embryo is brought into direct contact with atmospheric oxygen, and secondly, the inhibitor is removed. Presumably intact seeds do not germinate in the dark because of the presence of the inhibitor and also because the seed coat restricts the entry of oxygen.

A direct connexion between the influence of the inhibitor and the effect of oxygen is provided by the results of experiments performed with leached seeds. Scratching the pericarp of unleached seeds results in approximately 20 per cent germination in the dark in air. However, if leached seeds are scratched, the percentage germination in the dark, in air, is of the order of 60 per cent.

Thus it would seem that when some inhibitor is removed, the ordinary atmospheric oxygen tension is sufficient to promote the germination of many more scratched seeds in the dark and it is even possible to secure the germination of some, although only a small percentage, of intact leached seeds in the dark in higher oxygen tensions. Furthermore, it has been found that although completely isolated embryos germinate in the dark, in atmospheres containing only 1 per cent oxygen, the minimum oxygen requirement for germination is very much higher if the pericarp is still present, even though this has been cut away so as to bring the embryo into direct contact with the surrounding atmosphere.

One possible explanation of these results is that oxygen is involved in the deactivation of the seed-coat inhibitor, possibly by oxidation mediated by an enzyme system. On the basis of this hypothesis, it is easy to understand that although, in slit seeds, the inhibitor is still present and presumably diffusing inwards to the embryo, oxidation of the inhibitor is taking place at the same time. In scratched seeds, in air, sufficient oxygen is not entering to remove the inhibitor. But if the inhibitor has been previously leached out, the minimum oxygen requirement is less, and greater germination of scratched seeds occurs in air.

This is in agreement with results obtained by Wareing and Foda[3], who found that the inhibitor present in *Xanthium* embryos disappears in high oxygen tensions, before any visible germination changes have taken place. Furthermore, they have been able to obtain an enzyme preparation from the embryos which is capable of destroying the inhibitor *in vitro* in the presence of oxygen.

By analogy, the evidence presented above for birch seed would justify the assumption that a similar basic mechanism is operative in these seeds also, although, as yet, it has not been possible to demonstrate this.

It is unlikely that the role of light is in the destruction of the inhibitor, since one would not expect any photoperiodic effects if this were true[1]. It is more probable that light is directly involved in the production of a promotive agent which can overcome the effect of the inhibitor.

Glutamic Acid Decarboxylase in Legumes

Since the pioneer researches of Okuniki[1,2] and Schales and his associates[3-5] on glutamic acid decarboxylase, rather scanty data have been made available on amino-acid decarboxylases of plants. Most of the work deals with glutamic acid decarboxylase of higher plants; so it was thought of interest to study the enzyme system in the case of dry seeds of legumes.

The assays were carried out by means of Warburg manometric measurements at 35° C. Healthy, well-formed seeds were freed of contamination, if any, by thoroughly cleaning them with permanganate solution followed by copious amounts of distilled water. These were dried, finely powdered and stored in sterile bottles in a refrigerator. 3 gm. seed powder was extracted with 100 ml. *M*/15 phosphate buffer (*p*H 5·8) for ½ hr. at room temperature (28° C.). The extract was then passed through muslin and the activity of 4·0 ml. suspension was determined.

Of the leguminous seeds investigated, field bean appears to be the richest source of glutamic acid decarboxylase and is being used for the preparation and purification of this enzyme. In this bean, the product of decarboxylation was identified as γ-amino-butyric acid by paper chromatography. Field bean extract lost its activity on dialysis at 4° C. for 18 hr., which could be partially restored by addition of pyridoxal-5-phosphate. Addition of pyridoxal phosphate to the original extract was also found to enhance its activity considerably. This activating influence of pyridoxal phosphate suggests that the same is the coenzyme of the decarboxylase.

Table 1

Seed	Botanical name	Activity c.mm. CO_2/20 min./gm. dry seed
Field bean	*Dolichos lablab*, L.	1,180
Double bean	*Vicia faba*, Moench	97·54
Aconite bean	*Phaseolus aconitifolius*, Jacquin	95·72
Cow-pea	*Vigna catjang*, Walp.	306·1
Green pea	*Pisum sativum*, L. (Indian variety)	30·24
Black pea	*Pisum arvense*, L. (Black variety)	28·30
Bengal gram	*Cicer arietinum*, L.	95·96
Green gram	*Phaseolus aureus*, Roxb.	346·9
Lentil	*Lens esculenta*, Moench	nil
Red gram	*Cajanus indicus*, Spreng.	58·2

Further studies on the purification of the field bean glutamic acid decarboxylase are in progress. The leguminous seeds are also being tested for other amino-acid decarboxylases.

We are thankful to Dr. K. V. Giri for the gift of γ-amino-butyric acid and to the Government of India for the award of a senior research scholarship to one of us (L. K.).

Endosperm and Seed of *Wolffia*

Since the days of Hegelmaier[1] there has been little or no work on the embryology and seed structure of *Wolffia*. Recently[2], I pointed out the probability of a cellular endosperm in this genus. Later, the occurrence of a cellular endosperm was also confirmed in *Lemna paucicostata*[3], which contradicts Lawalrée's[4] report of a helobial endosperm in *L. minor*.

Abundant flowering material of *Wolffia microscopica*, available at Delhi, has enabled me to make further observations on the endosperm and seed structure of this plant. The first division of the primary endosperm nucleus is followed by a transverse wall resulting in the formation of a micropylar and a slightly smaller chalazal chamber (Fig. 1). At this stage the zygote is still undivided. Next, there is a transverse division in the chalazal and a vertical division in the micropylar chamber (Fig. 2); meanwhile, the zygote has divided to form the 2-celled proembryo. No free nuclear divisions occur at any time.

An interesting point concerning the structure of the mature seed is that the inner integument is completely crushed except at the micropylar end, where its apical portion forms the so-called operculum. The outer integument persists but comprises only a couple of layers, of which the outer develops reticulate thickenings.

Most of the endosperm is consumed; only one layer remains and surrounds the embryo. The cells are packed with reserve food materials except in the chalazal region.

The embryo presents a striking resemblance to that of *Lemna*. While still enclosed within the seed, it has already produced the first frond (f_1) as well as its daughter frond (f_2); and even the initials of the granddaughter frond (f_3) are recognizable. Fig. 3 shows a longitudinal section of the mature seed in which the frond has been cut in a plane at right angles to its flat surface. It is attached to the main body of the embryo by a very short pedicel. On one side it is enclosed by the 'suspensor' and on the other by the 'cotyledonary sheath'. Fig. 4 is an adjacent section in which the outline of the daughter frond

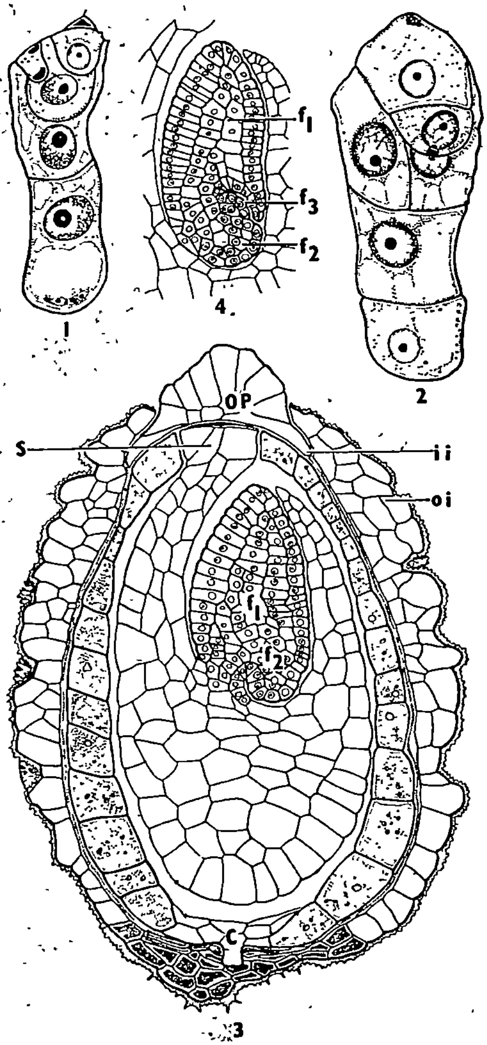

Fig. 1. Longitudinal section of ovule showing zygote and two-celled endosperm ; one synergid, remnants of the pollen tube and the degenerating antipodals are also seen (× 450). Fig. 2. Two-celled proembryo and four-celled endosperm (× 450). Fig. 3. Longitudinal section of mature seed; note the first frond (f_1) and its daughter frond (f_2) (× c. 166). Fig. 4. Part of a successive section of the same seed showing also the granddaughter frond (f_3) (× c. 166). (c, Caecum ; f_1, first frond ; f_2, daughter frond ; f_3, granddaughter frond ; ii, inner integument ; oi, outer integument ; op, operculum ; s, 'suspensor')

is more distinct, and the initials of the granddaughter frond are also recognizable. No root primordium could be distinguished.

The data presented above preclude any close relationship between the Lemnaceae and the Helobiales, as suggested by Lawalrée[4,5] ; on the contrary, they support the view that the Lemnaceae are closely allied to the Araceae.

Thanks are due to Dr. B. M. Johri for his interest in the investigation.

Foliar Zinc and *Oidium heveae* in Ceylon

Oidium heveae is a major pathogen on *Hevea brasiliensis* in Ceylon. Following the private communication of results on zinc deficiency in this connexion, since published by Bolle-Jones and Hilton[1], investigations were undertaken to see if this discovery had a practical bearing on the problem in Ceylon.

Three clones of *Hevea brasiliensis* were selected, namely, *LCB* 870, a high-resistant low-yielding strain ; *PB* 86, a medium-resistant high-yielding strain ; and *Tjir* 1, a highly susceptible, high-yielding strain. Five trees were selected from each clone and representative leaf samples taken, each sample being treated and analysed separately.

Two samplings were made at a fortnight's interval towards the end of the *Oidium* season. The first sampling was vacuum-oven dried and wet ashed with nitric and perchloric acids. The leaf content of zinc is expressed on the oven-dry basis. The second sampling was dry ashed in silica crucibles, and the leaf content of zinc for this sampling is expressed on the fresh weight.

Zinc was determined by the mixed colour dithizone method according to Sandell[2] using a *DU* spectrophotometer.

Tables 1 and 2 show the results obtained.

Table 1. Leaf Content of Zinc in *Hevea brasiliensis* as p.p.m. of Oven-dry Tissue

Sample	*LCB* 870	*PB* 86	*Tjir* 1
1	40	23	29
2	20	28	28
3	26	17	31
4	29	26	36
5	36	26	28
Average and S.E.	30·2 ±2 5	24·0 ±2·5	30·4 ±2·5

Table 2. Leaf Content of Zinc in *Hevea brasiliensis* as p.p.m. Fresh Tissue

Sample	*LCB* 870	*PB* 86	*Tjir* 1
1	3·6	4·2	4 7
2	2·4	6·6	4·2
3	2 4	5·7	6·1
4	3·6	4·7	5 7
5	4·7	3·3	4·2
Average and S.E.	3·54 ±0·47	4·90 ±0·47	4·98 ±0·47

There is no statistical significance in either result, though in Table 2 *Tjir* 1 is almost significantly greater than *LCB* 870 at about 18 : 1. The results are not completely conclusive in that, to obtain strictly comparable samples, leaves which had fully matured were selected. *Oidium heveae* in Ceylon is of primary importance in its attack on leaves up to the half-mature stage, when it causes defoliation. At the later stages only severe distortion of the leaf results from the attack. However, these leaves are comparable with those used by Bolle-Jones and Hilton, and it does not seem likely that the clone *Tjir* 1 could, in the course of the previous 20–30 days life of the leaf, have had a zinc concentration of the order one-eighth to one-tenth that of either of the other clones.

This work does not appear to support an alternative hypothesis for inter-clonal differences in *Oidium heveae* resistance to that already proposed by

Young[3], namely, that rate of cuticle thickening in the immature leaf is the determinant factor in the field.

Plant Life in the Vindhyans

THE possibility of the existence of plant life in the Vindhyans is a century-old problem and it begins with the report of the discovery of coal by Franklin (1833)[1]. Since then investigations have been carried out by various workers, though no definite existence of vascular plants in the Vindhyans could be established until 1950, when Ghosh and Bose[2] reported on their recovery of pitted woods and monolete spores in an Olive shale of the Semri Series (lower Vindhyans). Three years later, Jacob, Jacob and Shrivastava[3] found, in specimens of Jones's original collection of Suket shales, fragments of woody elements and five or six types of spores belonging probably to the primitive pteridosperms and pteridophytes and to doubtful primitive gymnosperms. They did not, however, recover winged spores or those with surface ornamentation in their material.

Recently, I had the opportunity for examining nineteen Vindhyan rock specimens, of which five belonged to the Kaimur Series (upper Vindhyans) and the rest to the various stages of the Semri Series of the Vindhyan system. These samples were obtained through the courtesy of the Geological Survey of India. Following the usual process of maceration in Schultze solution with every possible measure against laboratory contamination, I found a wealth of vascular microflora in fifteen out of the nineteen of the above specimens, the four barren samples being an Olive shale (Semri Series), two Porcellanites rocks (Semri Series) and one Bijaigarh shale (Kaimur Series). The detailed results of this work will be published elsewhere.

The main object of this note is to report on the occurrence of winged spores or those with surface ornamentation in the Vindhyans, more particularly in the Semri. The following is a descriptive list of a few of such spores.

1. *Microreticulate spore.* 44μ in diameter, brownish-yellow in colour, surface reticulate, lumen of the net 2–3 5μ in diameter; spore wall is not clearly seen and the spore body is somewhat distorted (Fig. 1).

2. *Punctate monolete spore.* 27·5μ × 37·4μ, yellow in colour, body densely pitted or reticulate with a bulging slit of dehiscence which is 33μ long; bulging-ends 3·3μ wide, spore wall is not clear (Fig. 2).

3. *Cingulate trilete spore.* Spore axis 88μ; yellow; slit axis 33μ long and 9–11μ broad; slit-rim 2μ thick; slit opening or aperture 5·5 μ; body provided with concentric ridges; spore body brownish in colour; spore wall 1μ thick; flange 3·5μ wide, yellow and wavy (Fig. 3).

4. *Monosaccate spore.* 114μ × 60μ; body distorted; frill is 9–11μ wide, brownish-yellow, longitudinally reticulate and attached to a thick rim; the rim is deep brown in colour and is 2–2·5μ wide (Fig. 4).

5. *Monosaccate spore.* 109μ × 88μ; spore body 77μ × 55μ, pale yellow in colour; frill is dark brown, longitudinally reticulate, 18μ wide approximately, but is not attached to any rim-like structure (Fig. 5).

6. *Disaccate spore.* 42μ in extension, spore body 23μ × 23μ, yellow in colour; wings reticulate, 16·5–15·5μ × 23–22μ in size (Fig. 6).

7. *Disaccate striate spore.* 44μ in extension; spore body 15·4 × 18·7μ, brown in colour, body spirally thickened with stripes; wings yellow, reticulate, 17·6μ–22μ × 25·3–22μ in size, base of wings 2·5μ thick (Fig. 7).

8. *Disaccate striate spore.* 49·5μ in extension, body 24·2μ × 33μ in size and is provided with six stripes which are more or less equidistant and 1·5–2·5μ thick, each extending in a curved manner to meet the spore wall on either side; colour, golden-yellow; wings 23μ × 33–28·5μ (Fig. 8).

Of the spores recovered, the saccate types have been found to occur abundantly in the Kheinjua stage (Semri Series) and very sparsely in a limestone from the Rohtas stage (Semri Series) and another specimen of Kajrahat limestone (Semri Series); the trilete ones occur in abundance in the Kheinjua and Rohtas stages, very rarely in the lower Kaimur and are completely absent in the Upper Kaimur and the basal stage of the Semri Series. It may be recalled

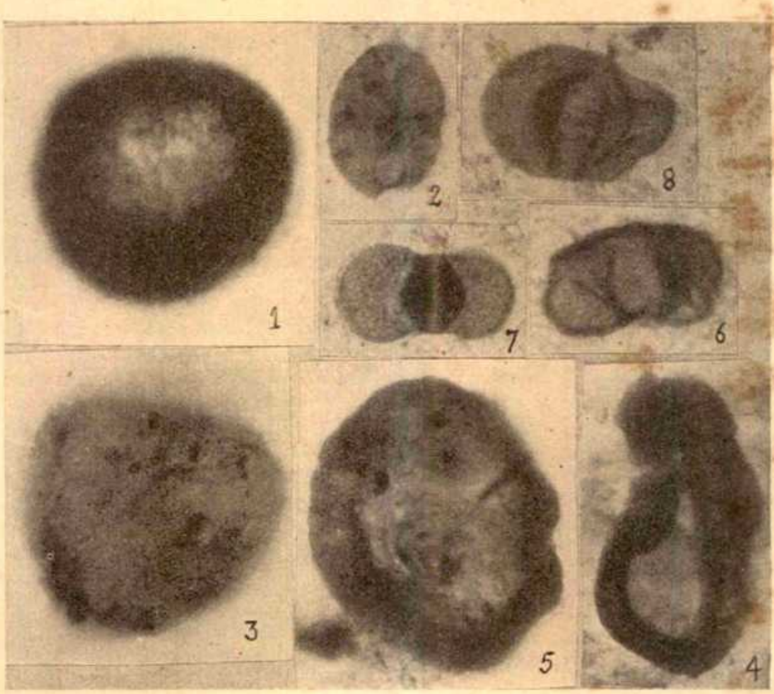

Fig. 1, × 800; Figs. 2–8, × 360

that (*a*) winged spores have been recorded in the Upper Cambrian of Spiti, Middle–Upper Cambrian of Kashmir by Jacob *et al.*[4] and the Cambrian of the Punjab Salt Range and Kashmir by Ghosh and Bose[5-7] and Bose[8]; (*b*) deltoid trilete spores have been found in the Cambrians of the Punjab Salt Range, and also in the Middle Cambrian of the United States by Ghosh and Bose[9]. On comparison, therefore, it may be suggested that the Kheinjua and Rohtas stages (Semri Series) are Middle–Upper Cambrian in age, with the consequence that (1) the Basal and the Porcellanites stages of the Semri Series become Lower Cambrian, and (2) the Kaimur Series, the Rewah Series and the Bhander Series become Late Upper–Post-Cambrian in age.

Specimens of Suket shales on which Jacob *et al.* carried out their investigation belonged to the upper part of the Semri Series; but I have done my work, as pointed out earlier, with material belonging both to the Upper and Lower Vindhyans. The various types of spores listed above prove beyond doubt that a well-developed flora of the Archegoniate group thrived in the Vindhyans and that "the Vascular land plants were in existence even as early as the Lower Cambrian"[3].

Thanks are due to Sri A. K. Ghosh for his guidance, to Dr. D. M. Bose, director of the Bose Institute, for giving laboratory facilities, and to Sri K. L. Chowdhury for photographing the plates.

Status of the Two Forms of Housefly occurring in South Africa

Although evidence[1], based on laboratory crossing experiments, exists for considering the two forms of housefly which occur in the Ethiopian region to be only subspecifically distinct from each other and from *Musca domestica s. str.*, nothing has been published on how they interact in Nature when they are sympatric. It is important to know this, as it is well known that some species will interbreed in the laboratory whereas they seldom, or never, do so in Nature. The behaviour of *M. cuthbertsoni* Patton and *M. curviforceps* Saccà and Rivosecchi[1] (*vicina* auct. not Macquart), both of which occur at Johannesburg, has therefore been investigated.

Synchronous samples of the domestic population (caught in and immediately outside buildings) and the feral population (caught well away from buildings) were made on a farm some thirty miles from Johannesburg. The frons ratio (width of frons at the narrowest point/width of head at the widest point) and the shape of the paralobi (inferior forceps) of the genitalia were determined for all males. The results of the frons ratio analysis are presented graphically in Figs. 2 and 3. These and the study of the paralobi revealed that *curviforceps* occurred mainly in the domestic environment and *cuthbertsoni* mainly in the fields. Thus they are more or less ecologically isolated. Many males in both populations had, however, paralobi which were intermediate in shape between the two typical forms (Fig. 1). Since I have found that laboratory hybrids between these two forms have paralobi of intermediate shape, this is interpreted as indicating that natural hybridization does occur. These results have been confirmed by subsequent collections.

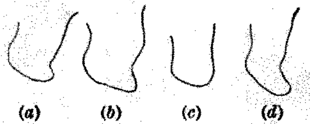

Fig. 1. Paralobi: (*a*) Hybrid. (*b*) *M. domestica curviforceps* (Johannesburg). (*c*) *M. domestica cuthbertsoni* (Johannesburg). (*d*) *M. domestica curviforceps* (Tongaland)

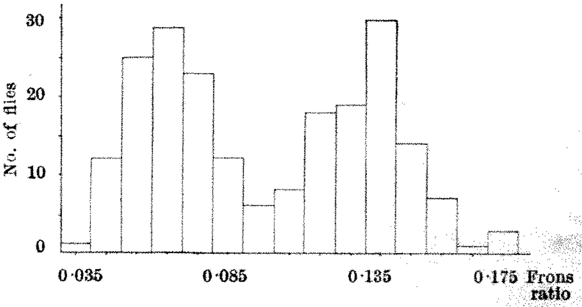

Fig. 2. Frequency distribution of the frons ratio in houseflies (domestic and feral) on a farm near Johannesburg

This evidence of the occurrence of natural hybridization between *cuthbertsoni* and *curviforceps* indicates that they are not specifically distinct, despite the fact that they are often sympatric in the original sense of the term.

Musca domestica s.str. and *curviforceps*, I can confirm, are completely interfertile in the laboratory, and, since they are allopatric, it is convenient, for the reasons given by Mayr[2], to consider them only subspecifically distinct despite their morphological differences.

It is possible that *cuthbertsoni* and *curviforceps* are now often sympatric because of extensions of range by *curviforceps* as a follower of man.

While studying the paralobi of Johannesburg *curviforceps*, it was noted that they were not as curved as those of the type series. This, I believe, may be due to the hybridization which I have shown to occur at that locality. This view receives some support from the fact that in Tongaland (lat. 27° 9′ S.; long. 32° 15′ E.) a population occurs which has very strongly curved paralobi as in the type series. These flies were caught in and about the tents of a camp in the bush. A search for *cuthbertsoni* proved fruitless. An alternative explanation is that the flies with

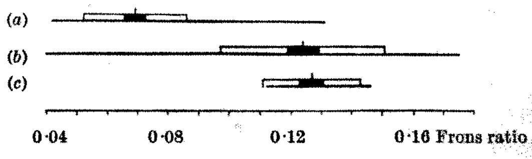

Fig. 3. Frons ratio: range of variation, mean, two standard errors of the mean on either side of the mean, and a standard deviation on either side of the mean for: (*a*) feral population, Johannesburg ($n = 99$); (*b*) domestic population, Johannesburg ($n = 109$); (*c*) domestic population, Tongaland ($n = 44$)

strongly curved paralobi are linked by an altitudinal cline to those with moderately curved paralobi. This alternative will be tested by further collecting.

A full report of this work will be published in due course. I am indebted to Prof. G. Saccà for help in various ways.

Occurrence of *Polydora pulchra* Carazzi in British Waters

WHILE studying the seasonal variation in plankton and hydrography of the plaice ponds at the Marine Biological Station, Port Erin, I came across a dense population of larvæ belonging to the species *Polydora pulchra* Carazzi (Polychaeta Spionidae). The identification is based on the key, descriptions and figures given by Hannerz[1]. The identification was further confirmed when the larvæ metamorphosed in the laboratory.

Carazzi[2] was the first to describe *pulchra* as a variety of *Polydora antennata* Claparède; but recently Hannerz[1] separated the variety and classed it as a distinct species with the name *Polydora pulchra* Carazzi. There are no previous records of either *Polydora antennata* or *Polydora pulchra* in British waters (Tebble, N., personal communication). Adult specimens have not yet been found in British waters.

Polydora pulchra has been very rarely reported. The only records are those of Fauvel[3] and Hannerz[1]. Fauvel found the species in the Mediterranean at Naples and in the Atlantic off northern Spain, while Hannerz found three individuals in southern Sweden. The occurrence of *Polydora pulchra* at Port Erin thus extends the known distribution of the species into the Irish Sea. Observations on the behaviour of the larvæ of *Polydora pulchra* and their resistance to changes in temperature, *p*H and salinity are being published elsewhere.

I wish to thank Dr. N. S. Jones, of Port Erin, and Mr. Norman Tebble, of the British Museum (Natural History), for confirmation of the identity of the larvæ.

An Unusual Method of capturing Prey by a Cuttlefish

IT is usually assumed that the typical shallow-water decapod cephalopods are active hunters and seek out their prey rather than wait for the prey to [illegible] them. It does sometimes occur[1] that a[illegible] lying passive, half buried in the sea bott[illegible] when food, such as a prawn or a crab, [illegible] the tentacular arms are rapidly unf[illegible] to secure the prey. In contr[illegible]

The observation was made in the late afternoon in the Straits of Singapore, some six miles offshore, from the Fisheries Research Station's launch, the *Chermin*, during the interval between two of the routine series of plankton hauls which are made in this area. At the time, the engine was shut off and the boat was drifting with the tide in a fairly extensive patch of *Sargassum* weed. The sea was glass-calm.

Through a break in the weed a small cuttlefish of about six inches length could be seen, floating some twelve inches below the surface. It was lying horizontally, the arms typically bunched together, there being no sign of any movement except from the suckered tips of the tentacular arms. These were extended above the head, inclined slightly forward, straight, excepting the distal suckered portions, and were slightly divergent. Both the tips of the tentacular arms were pendulous and slowly waving about in the water. Since the water was so perfectly calm, and there being no movement of any part of the submerged fronds of the *Sargassum* weed, it is reasonable to assume that the cuttlefish was waving them. This assumption is supported by the distribution of colour over the body. All the body, excepting the suckered areas of the tentacular arms, was of a uniform dull brown colour, very similar to that of the *Sargassum* weed. The suckered areas of the tentacular arms were white and very prominent.

It should be added here that I am well acquainted with the appearance of moribund and dying cuttlefish, and the possibility of the cuttlefish discussed here being moribund was considered, and rejected, since there was no indication whatever of it being other than healthy and normal in its behaviour.

Several times during some ten minutes of observation, small fish, which were clustered under the *Sargassum* weed, left their place of shelter to investigate the white tentacle tips. When the fish approached close to the tentacular arms, the cuttlefish attempted to catch them by a sudden dart forwards and securing them with the arms. During the period of observation the attempts were, unfortunately, unsuccessful. The cuttlefish did not exhibit any colour changes when approached by the fish, or when attempting to catch them.

Thus, although the actual capture of the prey was not observed, it was an undoubted case of an animal, accepted as being a hunter of its prey, deliberately and successfully luring its prey to it.

compatibility, ranging from combinations where none of the seeds was viable to those in which as many as 50 per cent of the caryopses germinated, that is, a high seed-compatibility[2].

Table 1 summarizes some of the results obtained after irradiating inflorescences of the two species at about 7 days prior to anthesis by means of a cobalt-60 source.

In general there is a significant reduction in seedset after 250–500 r. This is followed by an increase at 1,000–2,000 r.; but further increases in dose again result in a decline.

The effect of irradiation on seed-compatibility, although similar to that observed for seedset, showed a greater variability. Nevertheless, the results still fit into a general pattern if one takes into account first the direction of the cross and secondly the normal seed-compatibility of the genotypes involved.

In the *L. perenne* by *F. pratensis* matings the drop at 250–500 r. as well as the recovery at about 1,000 r. occurred to varying degrees in different crosses: in the normally incompatible cross (No. 1) and in the cross of low compatibility (No. 2), irradiation had little effect; in the cross of medium compatibility (No. 3) the initial drop as well as the increase at 1,000 r. was marked, but where the normal compatibility is high (No. 4) only a small reduction occurred at 500 r. Moreover, in the latter cross the germination percentage at the higher doses significantly exceeded that observed normally. Genotypic differences in the response to irradiation are therefore evident.

In crosses with *F. pratensis* as seed parent genotypic differences were again apparent in that the greater the genetic difference between the genotypes, the greater was the dose required for optimum production of viable seeds; for example, compare crosses (5) and (6). These differences were, however, partly masked by the fact that crosses showing a high degree of seed-compatibility where *L. perenne* was the femal[illegible] parent were not the most successful combina[illegible] in reciprocal matings; for example, cross[illegible] and (8).

While the results in themselves [illegible] assumed that with doses of up to 500 r. pollen-grain differentiation and germination and pollen-tube growth are not sufficiently affected to prevent fertilization, so that cytologically damaged pollen grains would participate in triple fusion. A proportion of the ovules may, however, undergo immediate degeneration, or else at some time after fertilization[3] the former results in a reduction of seedset, the latter in a decrease of seed-compatibility.

At doses higher than 500 r. selective elimination of the more severely damaged pollen grains presumably occurs either through lack of differentiation and germination[4] or possibly due to a slight disadvantage in rate of pollen-tube growth or by a combination of these factors. In consequence, seedset and germination should be higher than at 500 r.

The variable nature of the seed-compatibility data and especially the dependence of the response to irradiation on genotype suggest that irradiation has a second effect directly concerned with the degree of endosperm development. Since endosperm failure has been shown to be due to the genetic disparity which exists between the genomes of the two species (unpublished), it appears that irradiation induces changes in consequence of which endosperm development and hence germination capacity are improved. Superimposed upon the initial decrease in seed compatibility due to cytological abnormalities, we therefore presumably have changes which improve endosperm development. The latter is dependent on the initial disparity which exists between the genotypes.

The results reported form part of a general investigation into the nature of the differentiation and the barriers to successful hybridization between *L. perenne* and *F. pratensis*. They were carried out under the helpful guidance of Prof. P. T. Thomas.

Effects of Changes of Temperature on the Respiration of Certain Crustacea

WHILE much work has been carried out recently[1] on the long-term changes which take place in poikilotherms following a change from one constant temperature to another, little is known about the respiratory changes which take place within a short time after the temperature is altered. The object of the present study was to investigate this. Experiments have been carried out on the following Crustacea: *Neomysis integer*, *Hemimysis lamornae*, eggs of *Astacus pallipes*, *Diaptomus gracilis*. A detailed [illegible] made on *Artemia salina*. The rate of [illegible] was estimated using a continuous-flow [illegible] which will be described elsewhere. Most [illegible] were kept for two days or more at [illegible]ature of the experiment. They [illegible]paratus and after a few hours

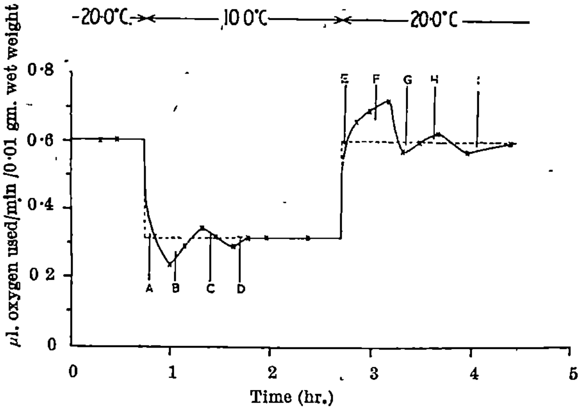

Fig. 1. Graph showing the effect of a change of temperature on the oxygen consumption of *Hemimysis lamornae*. The experimental temperature and the points at which it was altered are shown at the top of the figure

replaced at the initial temperature of the experiment. The oxygen consumption was followed throughout.

In every experiment on all the Crustacea examined it was found that the immediate effect of either a rise or a fall in temperature was to cause an overshoot in the oxygen consumption. This was usually followed by minor oscillations before a steady level characteristic of the new temperature was reached (Fig. 1). In *Artemia* the steady level was maintained for at least nine hours after the temperature was altered.

Overshoot in oxygen consumption following a change in temperature has been previously reported from a number of fish[2], *Cyclops*[3], *Planaria*[4]. It has been found in some individuals of *Astacus*, but apparently not in others[5]. In fish, however, overshoot appears to be of much longer duration than in Crustacea, and several days or even weeks pass before the steady level of oxygen consumption is reached at the new temperature.

It was found that *Artemia* anæsthetized with ether still showed overshoot in oxygen consumption even though all locomotory activity had ceased.

While the overshoot effect was found in all the oxygen consumption experiments, it could not be detected in any of the similar experiments on carbon dioxide output in *Artemia*. Here the steady level of output was reached within a few minutes at the new temperature. Because of the absence of overshoot in carbon dioxide output there are marked fluctuations in the respiratory quotient immediately following a change of temperature (Fig. 2).

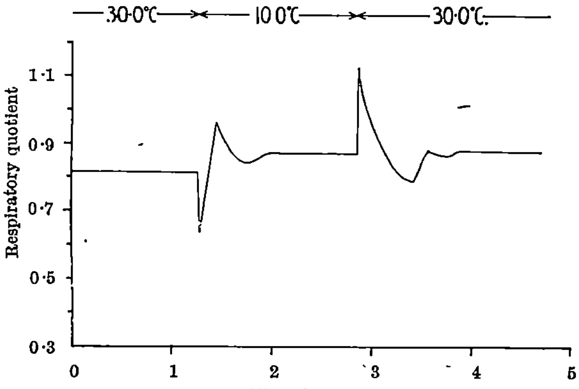

Fig. 2. Graph showing the fluctuations in the respiratory quotient in *Artemia salina* which follow changes of temperature (shown at the top of the figure)

The widespread occurrence of overshoot in oxygen consumption, and particularly its occurrence in the eggs of *Astacus*, suggests that the effect may be inherent in the organization of some organisms or tissues. All the results can in fact be satisfactorily explained if the organism is considered as behaving as a steady-state system. Several authors[6] have pointed out that the metabolism of living organisms can be interpreted in this way. According to steady-state theory the metabolic processes of an animal, when it is kept under constant environmental conditions, should tend to proceed at constant rates. When conditions are altered a new state should eventually be established in which these processes again proceed at constant rates, which are, however, different from the rates in the first state. When the level of oxygen consumption is steady at constant temperature the organism can be considered as being in such a steady state.

The properties of theoretical steady-state systems have been studied in some detail[7]. Many of the systems studied consist of sequences of consecutive or cyclical reactions connected by diffusion with constant external sources and sinks. Even in very simple theoretical systems of this type it has been shown[8] that overshoot curves may occur during the transition between two steady states. Overshoot may occur in such curves showing the relationship between rate of entry of material from an external source and time, when the temperature of the system is changed. It is possible that the observed overshoot in oxygen consumption (Fig. 1) is due to the same sort of reason, namely, a temporary piling up or a deficiency of metabolic substances. If this view is correct the fluctuations in the respiratory quotient (Fig. 2) found experimentally can also be explained, and were in fact predicted from the properties of simple theoretical systems[8]. Furthermore, a 'cost of transition' is to be expected[7,8]. That is, in Fig. 1 $(F + H - E - G - I)$ should be greater than $(B + D - A - C)$. This was the case in most of the experiments. The mean 'cost of transition' for *Artemia* for the temperature-change 20 → 10 → 20° C. was 0·545 μl. oxygen/0·01 gm. wet weight (mean of three experiments).

It would thus appear that the overshoot effect in oxygen consumption, which has been referred to as 'shock effect'[9], and 'acclimatization'[10] by some authors, can be interpreted satisfactorily in terms of steady-state theory.

These results will be published in detail elsewhere.

Isolation of Active Nematocysts of *Metridium senile* and their Chemical Composition

DURING the past half-century, there has been recurrent interest in the chemical nature of the stinging capsules of cœlenterates. Mainly two lines of investigation have been pursued. Toxic extracts of the tentacles or whole animal have been examined[1], and histochemical studies have been made. Both these approaches have yielded interesting information for speculation, but as Hyman[2] has pointed out, "On the whole it must be concluded that the nature of the nematocyst toxin is unknown, since the extracts mentioned above include tissues as well as nematocysts . . .", and one cannot expect the histochemical approach to yield the definitive answers.

Since the toxins of nematocysts would be useful substances for testing the immune antitoxic responses of a variety of marine invertebrates, studies were undertaken to find a way of isolating active nematocysts in a purified form and in sufficient quantity to allow chemical analyses and the isolation of the toxin. A method has been found of doing this, and it has afforded some information about the chemical nature of the wall and internal contents of the nematocysts of *Metridium senile*.

Briefly, the method involves maceration of the whole anemones in a Waring blendor with an equal volume of 1 *M* sucrose in sea water (maceration in sucrose solution was originally suggested by Miss Eleanor Dodge, Zoology Department, University of Washington). The creamy suspension is passed through graded screens with openings of 1·168, 0·589, 0·295, and 0·147 mm. with the aid of suction. Tyler standard screens customarily used for geological investigations were fitted on to a Buchner funnel with the aid of masking tape. The suspension after this filtration consists of nematocysts, fine tissue debris, dissolved tissue constituents and very fine sand. The amount of sand can be greatly diminished by keeping the anemones on a wire screen for several days before macerating.

Centrifugation of the suspension at approximately 1,000 rev./min. for fifteen minutes collects the nematocysts, and they are washed with additional sucrose solution to free them of soluble materials. Differential centrifugation in a small International clinical centrifuge finishes the purification. 15-min. centrifugations are used to collect the nematocysts and free them from fine tissue fragments. 15-sec. centrifugations are used to remove the sand. After five or six such centrifugations, the material appears to be all but completely free of both the sand and tissue fragments when examined microscopically, and is chemically consistent from batch to batch with respect to total nitrogen and hexosamine content. The nematocysts may be discharged with distilled water, dilute acid or base, sodium thioglycollate, or methylene blue, and the material released is toxic to those animals tested: the barnacle, *Balanus glandula*, and the snail, *Littorina planaxis*.

Chromatographic analyses of hydrolysates of the walls and tubes after discharge have revealed the presence of eighteen amino-acids: cysteine, aspartic acid, glutamic acid, serine, glycine, histidine, lysine, arginine, threonine, alanine, tyrosine, proline, valine, methionine, phenylalanine, leucine, isoleucine, and tryptophan. Two-dimensional chromatograms were developed with phenol/water (80 : 20), followed by butanol/acetic acid/water (4 : 1 : 5). Isatin and ninhydrin were used for the detection of spots. In addition, a hexosamine resembling galactosamine and a uronic acid resembling glucuronic acid were detected in acid hydrolysates through the use of one-dimensional chromatograms with ethyl acetate/pyridine/water (2 : 1 : 2) and *p*-anisidine hydrochloride or ninhydrin for the detection of spots. Quantitative determinations[3] of these carbohydrates has revealed that they are present in an equimolar ratio which may indicate the presence of chondroitin sulphuric acid; a polysaccharide similar in solubility characteristics has been isolated. These findings suggest that the walls may be formed of a cartilagenous material.

The material released on discharge of the nematocysts in distilled water shows on hydrolysis the same amino-acids, with the exception that tyrosine and tryptophan appear to be lacking. The same hexosamine and uronic acid are present, but in this material they are in a molar ratio of four hexosamines to five uronic acids. It is still uncertain whether the internal mucoproteins are of more than one species. In addition to the mucoprotein material, two hydroxyindoles have been detected. One of these, which is extractable with ether from acidified material, resembles 5-hydroxytryptophan with regard to its colour reactions and fluorescence. The other, which is extractable with ether from basic solutions, resembles bufotenine (N dimethyl 5-hydroxytryptamine) with regard to chromatographic development in basic, neutral and acid solvents. In addition to giving the bluish Ehrlich reaction, it fails to give the greenish-yellow colour of 5-hydroxytryptamine with ninhydrin in acetone. This latter substance has recently been found in tentacle extracts of *Metridium*[1]. Further work is under way on the identification of these substances.

The analyses, which have been carried out to this point, indicate that the material injected into the prey of these anemones is a mucoprotein with either adsorbed or free hydroxyindoles. It is hoped that through the investigation of purified suspensions of nematocysts their nature will be revealed.

Larvæ of the Polypterid Fish *Erpetoichthys* Smith

WHEN J. S. Budgett studied the *Polypterus* larva in the Niger Delta in 1903, he also searched for larvæ of the closely related *Erpetoichthys*, but did not find any. Apparently later workers have been equally unsuccessful, since there seem to be no records of juvenile *Erpetoichthys*. It was assumed that *Erpetoichthys* would possess a larval stage similar to that of *Polypterus*, with pinnate external gills; but this had not so far been confirmed.

On March 17, 1956, towards the end of the dry season, I caught two young specimens of *Erpetoichthys* at Aiyetoro about 40 km. west-north-west of Abeokuta in south-west Nigeria, both still in the larval condition. The find was made at the point where a small bridge on the Iboro Road crosses a swamp in the middle of the township of Aiyetoro. The water-level was very low, probably at its lowest, and the brook traversing the swamp was a mere trickle. The swamp itself consisted, at this point, of thick black mud, more than 50 cm. deep and with practically no water above. An enormous growth of *Pistia* was resting directly on the mud surface, the lower layers forming a fairly compact mass of decaying vegetable matter. The two young *Erpetoichthys* were found in a lump of this mud, scooped out of the swamp a few metres from the brooklet and spread on the road.

Before being killed and preserved, the specimens were kept alive in an aquarium for about three weeks at University College, Ibadan. One was about 6 cm. in length, the other about twice as long, and both had well-developed external gills resembling those of larval *Polypterus*. Frequent air gulping seemed to indicate that the lungs were already functional; this took place at short regular intervals, even in well-oxygenated water.

The finding of larval *Erpetoichthys* at Aiyetoro was unexpected as the place was outside the known area of distribution of the species. *Erpetoichthys* is said not to occur west of the Ogun River system; but the small stream draining the swamp at Aiyetoro belongs to the more western Yewa system. Moreover, and probably more important, Aiyetoro is a typical inland locality, more than 80 km. from the lagoon and coastal swamps. This is in contrast to the statements in the literature, which describe *Erpetoichthys* as a coastal form, confined to deltas, lagoons and estuaries[1], and raises the question whether this species migrates inland to spawn. If so, this would explain why searching for its young stages in the coastal region has not been successful.

A more complete account of the observations on larval *Erpetoichthys* will be published elsewhere. Field-work with the aim of throwing light on the distribution and breeding of this species is being continued.

Rate of Heat Production by Bull Spermatozoa

DURING some work on a problem unrelated to the present communication, a microcalorimeter was developed based on the 'Callendar Radio-balance'[1]. This calorimeter has been used for measuring the rate of heat production of unbuffered bull semen under anaerobic conditions, and although the calorimeter was not ideally suited to the work some results have been obtained which might be of interest to workers in the field of fertility.

Measurements were made on unbuffered whole semen from a bull of proved fertility. The measurement showed that there was a fall in rate of heat production from approximately 200 micro-watts/ml. of semen at 1 hr. after incubation at 37° C. to approximately 35 micro-watts/ml. of semen at 3 hr. These rates of heat production were, however, close to the sensitivity limit of the micro-calorimeter (measurements made on 0·055-ml. sample) and for this reason the accuracy of the measurement is not high. T. Mann[2] has published a curve showing the normal course of fructolysis in an unbuffered specimen of good quality bull semen at 37° C. From the rate of disappearance of fructose, the rate of heat production has been estimated by making the following assumptions: (1) the process is anaerobic; (2) the principal heat-producing metabolic activity is fructolysis; (3) the semen from the bull on which the fructolysis measurements were made was similar to that on which our measurements were made as regards sperm quality, buffering capacity of semen, initial fructose content, etc.—the sperm density is known to be similar in both samples; (4) the heat liberated (ΔH) in the reaction, 1 gm. mole of fructose to 2 gm. mole of lactic acid, is 23,000 calories (ΔF is approximately $-47,000$ calories).

The value so obtained for the rate of heat production 1 hr. after beginning of incubation at 37° C. is 160 micro-watts/ml. of semen. The trend of the curve for rate of utilization of fructose compares with that for the measured rate of heat production. The agreement of the measured and calculated values is encouraging and suggests that the method might be used for throwing additional light on the nature of the metabolic process (for example, whether fructolysis is the main energy-producing metabolic process).

It is interesting to compare these figures with an estimate of the energy requirement for spermatozoa *movement* made by Lord Rothschild[3] using formulæ developed by Sir Geoffrey Taylor[4,5]. The estimates, using two separate formulæ, are $3 \cdot 74 \times 10^{-7}$ erg/spermatozoa/sec. and $2 \cdot 04 \times 10^{-8}$ erg/spermatozoa/sec. The details are given in ref. 3 and the approximations in the hydrodynamic treatment are fully discussed in refs. 4 and 5. Our measurement converted to the same units is $0 \cdot 24 \times 10^{-5}$ erg/spermatozoa/sec. It appears, therefore, that on this basis the available chemical energy is much in excess of that required for propulsion.

Geographical Zonation of Atypical Caryotypes in Shieldbugs

BOTANISTS have postulated polyploidy as an adaptation to cold; but it has been shown that in ferns polyploids occur more frequently in Ceylon than in western Europe[1]. Little or no geographical analysis has been attempted of the occurrence of atypical caryotypes in insects outside the genus *Drosophila*, although in the shieldbug genus *Thyanta* three neotropical species have $2n = 14$ while three Nearctic species have $2n = 16$, 16 and 27 respectively[2].

From a number of sources the published values of the diploid number of 151 shieldbug species have been extracted during the course of a revision of the

Table 1. GEOGRAPHICAL DISTRIBUTION OF DIPLOID NUMBERS IN PENTATOMIDAE

	$2n = 14$	$2n \neq 14$	Total
Tropical and sub-tropical spp.	40	2	42
Temperate spp.	58	19	77
Total	98	21	119

higher systematics of the superfamily. Applying a new classification of Pentatomoidea (unpublished) and deleting species of doubtful determination or uncertain provenance, there remain 119 cytologically known Pentatomidae *sensu stricto*: these may be grouped as in Table 1. The ancestral diploid or type number, which here happens to coincide with the modal number, is 14; $12A + X + Y$ in males.

Inspection of Table 1 shows a statistically significant ($P = 0{\cdot}029$) association of atypical caryotypes with a temperate climate. The systematic positions of the atypical species and the presence of genera with a *Thyanta*-like range and caryotype pattern show that the association is not with a Holarctic distribution or monophyletic block although all the temperate forms so far examined live in the Palæarctic or Nearctic.

The present facts suggest either that: (1) rearrangements accompanying speciation in temperate climates tend, under the influence of some external factor, to be more often associated with gross caryotype changes than is the case in the tropics; or (2) gross changes, when they occur, are differentially selected and confer an enhanced survival value in temperate areas. In attempting an evaluation of these two hypotheses it must be remembered that the behaviour and general biology of shieldbugs show that the tropics provide optimum conditions for the group, while the rich fauna suggests it is also the area of maximum speciation.

Dr. R. E. Blackith, of the Imperial College of Science and Technology, London, has kindly assisted me with the statistical analysis.

Sexual Colour Differences in *Caranx ignobilis* (Forsk.)

Caranx ignobilis (Forsk.), the largest of the Indo-Pacific carangids, is a valued food fish from the East African coast to the Hawaiian Islands. The biology of this fish is being studied by one of us (F. W.), and it has been found that maturity is reached between 500 and 650 mm. standard length.

Routine observations on catches have shown that in specimens more than 500 mm. long there is a difference in colour with sex. The male has a dusky to black body, head and fins. In the female the body and head are pale to silvery, except for slight duskiness on the back. Small black dots may or may not be present on the upper sides of the body. The fins are pale to dusky hyaline.

These colorations refer to living and freshly caught specimens, as some hours later both sexes become a uniform dusky grey.

Sex prediction tests were carried out on a sample of 88 specimens, standard length 500–1,150 mm., and were correct in 90 per cent of cases. These colour differences develop with maturity. Most errors occurred in the size range 500–700 mm., and may have been immature fish. With specimens more than 700 mm. long prediction was nearly 100 per cent correct.

To our knowledge, these are the first recorded sexual colour differences in the Carangidae.
